The postoperative treatment should be conducted with great care. Frequent gastric lavage will relieve the vomiting. Cocaine hydrochloride, grain $\frac{1}{4}$ to $\frac{1}{20}$, may be given every four hours to allay the irritability of the stomach and to act as a stimulant. Morphine should be interdicted and its place taken by hypodermics of codeine, grain 1, every two or three hours if absolutely necessary. Pain after the operation is partially due to the stretching of newly formed adhesions or to solid material passing over the site of stricture. Stimulants, such as strychnine and adrenalin (15 minims every two hours) may be administered hypodermically, while atropine may be given in the same way to stimulate peri-

stalsis. High enemata are used every three hours until the bowels act. Thirst and the loss of the body fluids by vomiting, etc., are overcome by salt solution administered by rectum, or by hypodermoclysis, every four to six hours. To the salt solution are added adrenalin, or whiskey, as thought advisable. Small doses of calomel are given as soon as the stomach will tolerate them.

(To be concluded.)

MYOCARDIAL DEGENERATION.

By ALBERT E. ROUSSEL, M. D.,

PHILADELPHIA,

ADJUNCT PROFESSOR OF PRACTICE AND CLINICAL MEDICINE,
MEDICO-CHIRURGICAL COLLEGE; VISITING PHYSICIAN TO
THE HOSPITAL OF THE SAME; VISITING PHYSICIAN
TO THE HARVARD HOSPITAL, ETC.

Contrary to general opinion, if we accept the statistics of Schott, we find that diseases of the myocardium are more frequent than those of the endocardium in the proportion of 505 to 245. Of these 505 cases intellectual excesses have been noted in 140 cases, and in 68 cases these have conjoined with physical strain, while 212 of these patients, out of the total of 750, declared a significant family history.

Arteriosclerosis must be accepted as an important factor in many, but not in all cases of cardiac degeneration. It is worthy of remembrance that at least partial occlusion of the coronary arteries due to this cause may be compensated through the vessels of Thebesius with avoidance of otherwise resulting damage. Much more often, however, as a result of the diminished blood supply, the parts undergo an anæmic necrosis with resulting change in the muscular fibres either in loss of their nuclei or as shown by J. Renaut (1889) fragmentation or fracture of the fibre itself. This, doubtless, is the cause of more sudden deaths than any one valvular lesion. If the development is a more gradual one the muscle fibres which have undergone this anæmic necrosis are replaced by fibrous tissue with resulting increase in the size of the heart and subsequent gradual or sudden dilatation of its walls.

Necessarily, syphilis, rheumatism, and gout are the important ætiological factors in this degenerative change. The first two diseases should give a positive history, but an important fact, which is not appreciated as much as it should be, is that true gouty subjects (rare in this country) are less apt to show myocardial change than those in whom the joints have never been inflamed, but who suffer from other irregular manifestations of the disease. This American gout or

lithæmia which is often difficult of recognition is doubtless in many instances an explanation of those cases in which an apparent ætiological factor could not be found.

Parenchymatous degeneration is a condition met with in infectious diseases, typhoid, typhus, smallpox, pyæmia, remittent fever, particularly when protracted and accompanied by high temperatures. However, fever is not always a necessary condition, as it is found in other diseases when such degeneration does not exist. It is characterized by a pale, turbid condition involving the entire cardiac muscle, and relaxed, soft, brittle walls.

Fatty heart includes fatty overgrowth, with often resulting fatty infiltration and fatty degeneration. The first is an abnormal development of adipose tissue on or between the muscular substance of the heart, often impairing the contractile power, and not infrequently resulting in actual fatty degeneration. Hereditary predisposition exercises a marked influence on the occurrence of obesity, and no doubt also on resulting fatty infiltration. The condition is more than twice as common in the male as in the female, and is generally found after middle life. Improper food, sedentary habits, alcoholism, particularly in the consumption of malt liquors, are important factors.

Fatty degeneration is a change in the muscular fibres, by which the transverse striæ disappear being replaced by granules and globules of fat; a condition of defective nutrition, and, therefore, the result of various causes, old age, perhaps, associated with fatty infiltration, anæmia, either primary or secondary to repeated hæmorrhages; of wasting diseases, phthisis, cancer, and chronic suppurating, prolonged fevers, chronic alterations of the blood, purpura, scurvy, hæmorrhagic diathesis, certain poisons, phosphorus, arsenious acid, lead, antimony, and, last but not least, alcohol. Local causes, such as pericarditis and hypertrophied ventricular walls, as well as disease of the coronary arteries, may bring it about. The distribution of this change varies. When secondary to acute diseases it is generally uniform, but in the majority of all cases the left ventricle is more affected than the right.

A point of importance, as shown when we entertain the question of diagnosis, is that in pure fatty degeneration the size of the heart is normal or only increased slightly by the occurrence of secondary dilatation, and, not rarely, it is diminished. This condition, however, may and often does occur in hearts previously enlarged. The predisposing causes as regards sex and age

are the same as in cases of fatty infiltration. Habits of life have probably less influence in fatty degeneration. I have not infrequently seen it in persons of temperate habits, but suffering from long continued mental strain.

Brown atrophy is a common degenerative change, particularly in that portion of the heart muscle secondary to valvular affections. In the old and those who have died from wasting diseases, it is generally present. I have in the past three years seen two marked post mortem evidences of this kind in patients who had suffered repeated and profuse hæmorrhages from uterine fibroids. In several other instances of a similar nature I have been so impressed by the physical signs and symptoms of a weak heart that I have enjoined particular caution in the administration of ether in those cases where operations were indicated.

Amyloid degeneration of the heart is rare and not often recognized macroscopically.

Hyaline degeneration is sometimes met with in prolonged fevers.

Calcareous degeneration may occur in the myocardium.

These last three forms possess no clinical interest.

The consequences of myocardial disease necessarily depend upon the degree and character of the affection, and to a certain extent upon the parts involved. In all cases, however, the result must be loss of contractile power and thus lead to imperfect filling of the arterial system and consequent visceral anæmia. This, it is to be noted, is much more marked than is the correlative venous distention, which is so prominent an effect of dilatation of the heart.

In the *fibroid heart*, hypertrophy and dilatation usually coexist and suggest at least recognition of the heart as the main issue involved. Dyspnoea and dropsy are sooner or later present and the symptoms resemble those of dilatation of the heart. The first sound is weak and toneless and has been noticed to be weaker over the left than over the right ventricle when the former was more affected. A mitral systolic murmur may be present, but perhaps recognized only in the recumbent posture. The pulse is weak, irregular on exertion, and may be as infrequent as 30 beats to the minute. Cardiac pain may be present, but rarely to a marked extent. In many instances, however, the symptoms have been remarkably latent and death may be sudden apart from rupture or even the existence of an aneurysm.

The diagnosis of many cases of fatty degeneration is to my mind even more difficult than that

of a fibroid heart, and I am positive that often cases of this disease are not recognized even after a physical examination. This is due largely to the fact that as the size of the heart in simple, fatty degeneration is little changed, the area of dullness presents no alteration. The slight dilatation rarely leads to signs of enlargement. It must be remembered, however, that in a certain number of cases fatty degeneration may follow preexisting hypertrophy and dilatation. Significant are evidences of diminished force of impulse, the area which remains normal: of course, if dilatation has occurred, the impulse is diffuse. Both sounds of the heart are weakened corresponding to the impulse, but necessarily the first sound shows the greater alteration on account of the muscular change: it is of less volume, shorter in duration, and higher in pitch, resembling the normal second sound, which is, of course, correspondingly diminished on account of the weakened distention. In some cases the second sound is alone discernible.

The first silence is longer than normal, on account of the shorter first sound. Thus the sounds resemble those of the fetal heart, particularly when the action is rapid. If on repeated examinations where the area is not increased, there is noticed a greater relative diminution of the aortic second sound than of the pulmonic, it is fair to assume that the left ventricle is chiefly affected and vice versa. The greater involvement of the left ventricle can thus be demonstrated in the parenchymatous change resulting from high temperature in typhoid and other fevers.

The rhythm varies greatly. The action of the heart may be regular and normal in frequency, particularly if dilatation is not marked. More significant, but more rare, is infrequency of pulse with or without low tension. In these cases the pulse may drop to 40, 30, or even 20, beats a minute. This condition, when observed after middle life is, to say the least, suggestive.

An active business man applied last winter for an increase of \$20,000 of insurance, which was granted. Some weeks afterward he called my attention to the fact of the lowering of his pulse rate to about 58 beats a minute. A careful examination revealed evidences of cardiac degeneration, and notwithstanding treatment he died in an attack of angina (the first) within three months of his insurance examination.

True anginal seizures are comparatively rare and pain itself is not a common symptom. More often is there a sense of weight or uneasiness in the cardiac region with some shortness of breath on exertion. Syncopal attacks are not uncommon and vary in intensity: the degree may be so

great as to simulate apoplexy without, of course, resulting paralysis. They may come on suddenly independent of exertion and resemble asthma or a continuous sense of suffocation, or, as already remarked, muscular exertion may be necessary to bring them into evidence.

Other symptoms are pale skin, mucous membranes bluish and extremities cold, morale often depressed. Symptoms of venous distention are rare, except slight œdema about the ankles; gastrointestinal symptoms and constipation are common, but dropsy is never present without dilatation. It is only when this is present that albumin may be found in the urine. A point, however, which I consider of particular importance in these cardiac degenerations is the diminished amount of urine, which is often only one fourth or even one half the normal amount. The amount passed should, therefore, be carefully measured in all doubtful cases. According to Bouchard, there is diminished toxicity of the urine.

Coexisting degeneration of other organs often modifies the general character of the symptoms of fatty degeneration, but neither the existence of arteriosclerosis nor of the yellow arcus is pertinent to the diagnosis.

Fatty overgrowth rarely gives rise to distinctive symptoms, unless infiltration or fatty degeneration has supervened. Necessarily the heart sounds are less clearly conveyed to the ear, but in these cases it has often seemed to me that after exercise the heart sounds become more distinct, which we would not expect to occur, at least to the same degree, in cases of the degenerative form.

Prognosis.—Many patients die suddenly when the symptoms are either absent or not considered of sufficient importance to merit treatment; but too many cases of so called heart failure with fatal termination are recorded in patients who have recently been under observation and in whom the condition was unrecognized. In most cases the outlook is most serious, but perfect recoveries of the parenchymatous and fatty types, after typhoid fever and diphtheria, respectively, are everyday occurrences. To a lesser extent may this be said to be true of the attacks in the cases accompanied by arteriosclerosis and dilatation.

Treatment.—In that important group of cases characterized by a heart of normal dimensions and absence of evidences of dilatation, but existence of cardiac weakness, rest in bed for a certain period of time is probably the first indication. Easily digested food, largely nitrogenous

in composition, and attention to the condition of the bowels are of importance. The regular use of an after dinner pill or an occasional mercurial purge, alternating from time to time with high rectal irrigation, should be borne in mind. The importance of maintaining the digestive functions in as good condition as possible should not be forgotten, as an attack of indigestion may be followed by dangerous consequences. Strychnine, arsenic, and iron are the drugs which are of most use. The digitalis group is, as a rule, to be avoided, and in some cases I am satisfied that it is productive of harm. I am in the habit of making regular use of oxygen, two or three times daily for periods of ten to twenty minutes, and have continued this for weeks at a time with satisfactory results. In cases where there are evidences of increased arterial tension, the nitrites are of benefit. When the contrary is the case small doses of atropine may be tried with good results. Aromatic stimulants are, as a rule, better suited for syncopal attacks than whiskey or brandy, but the use of light wines is often beneficial. The patient is sensitive even to proper clothing and warm water for bathing. For restlessness, small doses of heroine guarded by atropine are useful. In Cheyne-Stokes breathing, strychnine, hypodermically, and oxygen may be administered. In attacks of angina, nitrite of amyl and nitroglycerin may be given hypodermically. As the patient improves, graduated exercise, either by the Oertel or Schott treatment, should be instigated. I am aware that there is, at least in this country, some doubt among the profession as to the propriety of using these methods in cases of fatty degeneration of the heart. Certain it is that the results are more uniform and satisfactory in cases of fatty overgrowth, but those of you who have examined and noted the at times excellent results obtained in the first group by these treatments, cannot but become partizans of the same. The group of cases attended with dilatation (generally the fibroid) must be given the treatment for that affection. In cases with a syphilitic history, the usage of potassium iodide for long periods should be carried out as some brilliant results have been reported.

2112 PINE STREET.

Gift to the Postgraduate School.—Announcement has been made that the New York Postgraduate Medical School and Hospital, Second Avenue and Twentieth Street, has received a gift of \$7,500 from Mrs. Richard T. Auchmuty, of No. 101 University Place.

COTARNINE HYDROCHLORIDE IN
UTERINE BLEEDING.*

By H. J. BOLDT, M. D.,

NEW YORK,

PROFESSOR OF GYNÆCOLOGY, NEW YORK POST-GRADUATE MEDICAL SCHOOL; ATTENDING GYNÆCOLOGIST TO ST. MARK'S AND THE POST-GRADUATE HOSPITALS, AND GERMAN POLIKLINIK, AND CONSULTING GYNÆCOLOGIST TO BETH ISRAEL, AND THE ST. VINCENT'S HOSPITALS.

Having made use of cotarnine hydrochloride (or stypticin, the name applied to it by its discoverer, Professor Martin Freund, of Frankfurt-am-Main) for the past seven years, to control bleeding from the uterus, I feel that my opinion of its therapeutic value has been established with exactness. Having now passed the experimental stage in the employment of the remedy, I am able to supplement my former report on the same subject, published in the *Medical News*, April 8, 1899, with the present contribution.

The drug is a fractionation product of the oxidation of narcotine, an alkaloid obtained from opium, and is a microcrystalline, yellow powder, soluble in water. It has an intensely bitter taste. Narcotine, under the influence of oxidizing agents, can be separated into an acid, opianic acid, and a base, cotarnine. It can then readily be converted into the hydrochloride of cotarnine. Chemically it differs from hydrastinine only in the substitution of the methoxyl group OCH_3 for one atom of displaced hydrogen.

The following is a résumé of the conclusions concerning its physiological action, the experiments having been conducted in the Pharmacological Institute of Berlin by Edmund Falk (*Therapeutische Monatsschrift*, Vol. IX, No. 12).

1. In cold and warm blooded animals it produces paralysis by its action on the motor sphere of the spinal cord. In the warm blooded animals a complete paralysis occurs late, usually only shortly before death.
2. A mild narcotic state, but neither sleep nor complete narcosis, is produced in warm blooded animals by its action on the cerebrum.
3. In rabbits and dogs by both internal and subcutaneous administration, it is productive of intestinal paralysis and fecal evacuations.
4. It has no direct primary influence in warm blooded animals on the heart, circulatory system, or blood pressure. The effects on the heart, pulse, and blood pressure are of secondary nature, through the influence of cotarnine on respiration; only in very large doses, and with long continued artificial respiration is a weakened heart action produced.
5. Its action on the respiratory centre after transitory irritation is paralytic; respiration is, therefore, increased at first, but subsequently rapidly sinks to a quietus.
6. Fatal termination is produced by paralysis of the

respiratory centre, but can at any time be kept in abeyance by artificial respiration.

There is a similarity in the therapeutic action of cotarnine hydrochloride and hydrastinine, which is explained by Rousse and Walton on the theory that both drugs augment cardiac activity, and possess oxytocic properties. According to these observers, the difference between hydrastinine and cotarnine hydrochloride is that the former causes circulatory modifications more rapidly, acting on the heart and abdominal vessels at the same time, while the action of the latter seems limited to the heart and is slower.

They also find that cotarnine hydrochloride slows the action of the heart in the frog and rabbit, whereas it exerts an accelerating influence in the dog; hence they utilized the latter animal in their later experiments. They find, contrary to the opinion of Falk and Marfori, that it exerts a tonic action on the circulatory system. Comparing it again with hydrastinine, they find the latter acts as a stimulant on the heart, like camphor and ether, whereas cotarnine hydrochloride can be compared, in its action on the heart, to digitalis; hence the difference in their indication when these drugs are to be used in the control of hæmorrhage. All observers agree that cotarnine hydrochloride causes fatal termination by its paralyzing effect on the respiratory centre.

The credit of making the first clinical observations belongs to Sigismund Gottschalk, of Berlin. Since then numerous clinicians in Europe have made careful observations and almost uniformly report most excellent results; not only in bleeding from the female genitalia, but also in instances of pulmonary bleeding, dental hæmorrhage, hæmaturia, and intestinal bleeding.

The cases for which it was used by me were 35 cases of fibromyomata. Eleven were more or less benefited by its administration, and twenty-four were not benefited at all. Its uselessness was most marked in instances of submucous tumors. I quote one example in which relief was very marked:

1. *Interstitial Fibroid*.—Mrs. R. S., aged 40 years; interstitial fibroid extending 4 inches above the symphysis; menstruation regular but very profuse, and from eight to ten days' duration. One week before the expected flow, 1 grain was administered three times daily; with the onset of the flow the dose was increased to $2\frac{1}{2}$ grains every three hours. The flow has been diminished to three days and is of only moderate quantity. This patient is still under observation. She has positively declined surgical intervention. (If the drug is not taken during a flow, the bleeding is more profuse.)

2. *Hæmorrhage from Uterine Cancer*.—There were nine patients with hæmorrhage due to cancer of the uterus. The result was negative in each instance.

* Read at the Southern Surgical and Gynecological Society, Birmingham, Ala.

3. *Postpuerperal bleeding* after removal of retained placenta particles or decidua. There were five such instances: the patients had had the remnants of conception removed by their family physicians, but still some atypical bleeding persisted. In all these patients complete cure followed in from two to six days. The following is an illustration: Mrs. W., 24 years old, was delivered of her first child six weeks before consultation; manual detachment of the placenta was undertaken; three days later her accoucheur curetted the uterus and removed the placental remnants. Some bleeding, however, continued up to the time when I was requested to see her in consultation, with a view of sanctioning another curetting. Not finding any indication that such procedure was necessary, I advised subcutaneous injection of a solution containing five grains of cotarnine hydrochloride, the injection to be repeated every eight hours until the flow ceased. The bleeding diminished after the first dose and ceased entirely after the sixth injection.

4. *Hyperplastic Endometritis*.—Out of 13 patients benefit was derived in 3 instances. All were subsequently curetted, but in eight patients even then the menorrhagia was not markedly diminished. Seven of this number were then cured with cotarnine hydrochloride, and one was not at all benefited. In the glandular form of endometritis the results were entirely negative.

5. *Retroversio-flexio with Endometritis*.—There were five instances of this class, but in only one patient was the menorrhagia relieved without resorting to surgical intervention, viz., R. T., aged 29 years, two children and one abortion at the second month, nine months before coming under observation. Menstruation during the last three months, profuse and of six to eight days' duration, which weakened the patient very much. The menorrhagia was the only symptom of which the woman complained. Inasmuch as the period always recurred regularly, the administration of cotarnine hydrochloride was begun in 1 grain doses two days before the next expected period, and as soon as the flow showed itself, $2\frac{1}{2}$ grains were ordered every three hours, this treatment to be continued throughout the period. The first time the flow was shortened to five days, and was of smaller quantity; the second month, to four days and was of moderate quantity, and the third month it was normal and of only three days' duration. The woman did not again report. The remaining patients not being markedly benefited were subsequently operated upon.

6. *Chronic Metroendometritis*.—Out of nine such patients, five were more or less benefited by the administration of the drug, and in four the result was negative.

7. *Various forms of non-suppurative pelvic inflammation*, the uterus itself not being markedly affected. Twenty-three patients. The pathological bleeding was subdued in 8 instances; was markedly improved in 9 cases; was somewhat improved in 3; and had a negative result 3 times. The following narrations may serve as illustrations: M. J., aged 28 years, married eight years, never pregnant. Menstruation regular, of three days' duration, but very painful. Amount of blood lost, small. Her physician dilated the cervix and curetted four

months previously. She was ill three weeks as the result of that interference. On examination the pelvis was found to be filled with an exudate which prevented mobility of the uterus. The para and perimetritis was diagnosed to be non-suppurative. The patient had atypical bleeding at varying intervals, from two to four weeks, and each bleeding was profuse, and from seven to ten days in duration. The remedy was ordered in doses of 1 grain three times daily when not bleeding, and as soon as blood showed itself $2\frac{1}{2}$ grains were ordered to be taken every two to three hours. The effect was marked; the amount of blood lost began to lessen from the beginning, and after three months of administration in the manner described, menstruation began to be regular, although considerable exudate was still present.

Chronic tuboovarian inflammation. A. G., 27 years old, one child three years previous to consultation. During the preceding two years the woman had been bleeding from eight to twelve days, losing a large quantity of blood at each period; prior to this the menstrual period continued but two to three days and the blood lost was moderate in quantity. She was ordered to begin with the drug three days before the expected flow, in 1 grain doses, and, on the appearance of bleeding, increasing it to $2\frac{1}{2}$ grains every two to three hours, according to the severity of the bleeding. The patient had been curetted three times; and it had been proposed to remove her slightly thickened and (as was shown on examination) sensitive Fallopian tubes and somewhat enlarged ovaries, yet four months of treatment with cotarnine hydrochloride as described, sufficed to rid her of the menorrhagia.

8. *Bleeding During Pregnancy*.—Patients who have slight irregular bleeding during pregnancy are greatly benefited by letting them take cotarnine hydrochloride. Usually these patients are much alarmed so long as such bleeding continues, and in my experience it ceases after a few doses have been taken. There has been no unfavorable symptom caused by its administration. In all there were eleven such instances.

9. *Profuse menstruation in virgins* without detectable changes being found in pelvic organs on rectoabdominal examination. There were seventeen such patients, and in only five was the result entirely negative. In one of these hydrastinine gave the desired relief. Five of the patients had dysmenorrhoea as a complication, and in two instances this was diminished by the drug. One illustration may suffice. E. L., aged 23 years. Menses began at 12 years, the flow being at irregular intervals of from six weeks to two months during the first eighteen months; then the flow was of moderate quantity and of two to three days' duration; painless. From the second year after the beginning of menstruation the flow gradually increased in quantity and duration, and was associated with much pain, so that at the time when the patient came under observation the flow was of from eight to ten days' duration, exceedingly copious, and associated with such severe cramp like pain that the young woman had to spend from three to four days in bed. Ordered cotarnine hydrochloride, 4 grammes, divided into 40 capsules, one capsule to be taken every six hours, beginning three days before ex-

pected flow; on the appearance of the flow and during it, one capsule every two hours; if the flow was not diminished in twenty-four hours then two capsules were to be taken every two hours. In three months this patient had the bleeding decreased to four days' duration and the dysmenorrhea was so much improved that she did not find it necessary to go to bed during the period.

10. *Atypical Bleeding During the Climacteric Period.*—If there was no pathological cause found for the occurrence of this symptom, the result has usually been satisfactory. It is necessary, however, to give it on the first sign of bleeding. The remedy has also been used in a few instances of uterine bleeding in patients in whom no cause at all could be found for the occurrence of the hæmorrhage, and in these instances, too, the result was fairly satisfactory.

It must of course not be expected that cotarnine hydrochloride is a panacea for all cases of uterine bleeding, but it has been found to answer better than any other remedy that I have used. If no effect at all is produced after three large doses (from $2\frac{1}{2}$ to 5 grains) have been given, it is useless to continue with the drug. In the cancer cases it was tried as a palliative measure prior to the palliative operation, but, as has been noted, without effect. It is likewise not recommended to continue its use in instances of fibroid if two hypodermic injections of 5 grains each at intervals of four to twelve hours do not cause a diminution of the hæmorrhage. One should resort to surgical intervention when necessary. It is intended here merely to call attention to a very valuable remedy for the relief of a symptom often met with by physicians; a remedy that may be advantageously tried with patients who decline immediate surgical intervention, or who are not in proper physical condition to risk such intervention. I do not coincide with those of my confrères who look upon gynaecology only from a surgical side.

It is reasonable to expect that one is in a position to make practical deductions after having used a therapeutic agent as extensively as I have employed that under consideration. While I am not as enthusiastic about its general use as a remedy to control uterine bleeding, yet there can be no question about its utility in many properly selected cases. In fact, in some instances it has practically served as a specific. Further, and this is important, no harmful action has been observed even when it has been administered in such large doses as five grains every three hours. Neither was it noticed in the employment of such large doses that it had a hypnotic effect as was maintained by Gottschalk, who attributed this action to the drug because it is a derivative of opium. The only semblance that I have observed, that might be construed into the supposition that cotarnine hydrochloride acts like a hypnotic in medicinal doses is that in some instances it also

relieved the various patients of pain associated with the profuse bleeding, and hence induced a restful condition. That its therapeutic value is not due to its possessing oxytocic properties, as has been stated by some writers, is best proved by the fact that in no instance of slight bleeding during pregnancy, in which the drug was administered, were uterine contractions produced, although the bleeding usually ceased. Further, Gaertig, in the lying in asylum with which he is connected, experimented with the remedy in instances of premature labor and in atony of the uterus, without observing any uterine contractions as the result of its administration.

It has been found that in instances of too profuse menstruation, the best plan is to begin with 1 grain doses three times daily about one week before the expected flow, and as soon as the flow begins to let the patient take $2\frac{1}{2}$ grains every three hours to be continued during the entire period. In instances of metrorrhagia, from $2\frac{1}{2}$ to 5 grains may be given at intervals of from two to three hours until the bleeding is lessened, then the dose may be decreased to from 1 grain to $2\frac{1}{2}$ grains at intervals of three to four hours. If a quick result is important, it is best to give 3 to 5 grains in a 10 per cent. solution subcutaneously into the buttocks, using the customary antiseptic precautions. The small doses recommended by our German confrères did not give me a sufficiently satisfactory result often. Because of the disagreeable taste of cotarnine hydrochloride, it is best administered in the form of capsules, ordering the pharmacist to put the powder dry into the capsules. It may, however, also be given in tablet form.

39 EAST SIXTY-FIRST STREET.

Philadelphia College of Physicians.—At the meeting of the College of Physicians, held February 1st, Dr. Charles Lester Leonard read a paper entitled *Recent Advances in the Technique of Röntgen Therapy*. Dr. Russell H. Boggs, of Pittsburgh, by invitation, read a paper entitled *The Treatment of Some Non-Malignant Diseases by the Röntgen Ray*. Dr. Enion G. Williams, of Richmond, Va., by invitation, read a paper entitled *The Treatment of Malignant Disease by the Röntgen Ray*. The discussion was opened by Dr. George C. Johnston, of Pittsburgh, by invitation. The honorary librarian announced the addition of forty-four volumes to the library during January. Dr. Ward Brinton was elected curator of the Mutter Museum. The president announced the following appointive committees: Finance committee, Dr. John B. Roberts, Dr. G. Fales Baker, and Dr. Samuel J. Dixon; entertainment committee, Dr. George E. de Schweinitz, Dr. Charles H. Frazier, Dr. J. Alison Scott, and Dr. George B. Wood; Alvarenga prize committee, Dr. Elliston J. Morris, Dr. John M. Swan, Dr. Stricker Coles, Dr. Alfred Hand, and Dr. Joseph M. Spellissy.

A BRIEF REVIEW OF THE TREATMENT OF PREPUERPERAL AND PUERPERAL HÆMORRHAGES.*

By CHARLES J. C. O. HASTINGS, M. D. C. M., L. R. C. P. I., L. M. K. Q. C. P. I.,

TORONTO, CANADA.

In view of the fact that a large number of the Fellows of this society are not engaged in obstetrical practice, I presume I should offer some apology for bringing this subject before you. The facts, however, of the cases being, fortunately, of rare occurrence and the results depending on the judicious and prompt action of the attendant, justify, if they do not in fact make it obligatory on our part, to have an occasional rehearsal as regards the best line of treatment in order that we may be well equipped for prompt action, as we can only hope successfully to meet an emergency by being prepared for it.

Wellington said that his greatest victories were achieved before the battles were fought. Napoleon maintained that he had conquered the greater part of Europe because the enemy didn't know the value of five minutes. Now if we hope to attain similar laurels in the field of labor we must keep our powder dry and know how to appreciate the value of every minute, for in these cases we are confronted by a formidable enemy which will promptly conquer if not conquered. My experience in private practice extending over nearly nineteen years is limited to two cases of unavoidable, two of accidental, and one of post partum hæmorrhage. From my personal experience and observations, the successful handling of these cases depends largely on the ability of the physician to properly classify them, as no method of treatment can be suggested that would be suitable for all cases. The advances in treatment of these cases, if they are an advancement, have been with the object of diminishing the infant mortality. If this can be accomplished without diminishing in the slightest degree the chances of the mother, then they may well be considered advancements.

If the child is viable, or if a severe hæmorrhage has occurred, labor should be induced at once. If on the other hand the child is not viable and there have been but slight hæmorrhages and the patient can be kept in the recumbent posture in a hospital, or otherwise carefully guarded, I think one is justified in temporizing, providing that the patient's friends, when advised of the nature of the case, are satisfied or desirous that such a course should be pursued.

Now, assuming that the child is viable or that a severe hæmorrhage has occurred, what is the best method of inducing labor and emptying the uterus?

If the patient is a primipara and the cervix will admit only one finger, and the os is rigid, the cervix should be drawn down with a strong tenaculum and held while the cervix and vagina are gently but firmly packed with iodoform gauze. If properly done this will usually stimulate uterine contractions and satisfactorily control the hæmorrhage, and when the packing is removed in a few hours, in a vast majority of cases the os will be sufficiently dilated to admit of digital dilatation by Harris's method. If, however, the pains have become strong and regular, the hæmorrhage is not severe, the head or buttocks are engaged, we may safely watch and wait, never leaving the bedside of the patient. Should there be any increase of hæmorrhage the membranes should be ruptured at once, so that the placenta may retract with the uterocervical walls and at the same time allow the presenting part to press down firmly on the bleeding surfaces. If this is not effectual in controlling the hæmorrhage, no time should be lost in bringing down a foot, but this must always be done very gently so as to disturb the placenta as little as possible and produce the least possible shock to the mother. I would like to emphasize here the fact that there is no means known to the profession to compare with the bringing down of a foot to control hæmorrhage in these cases. The means for its execution are always at hand and can be applied without the loss of one minute. This method has been in use now for about a hundred and thirty years, and as a safeguard to the mother has to my mind no peer as yet.

The condition, however, that we most frequently encounter when called to these cases is rather extensive hæmorrhage or evidence that severe hæmorrhage has occurred with the cervix fairly well dilated. Version should be performed by the Buxton Hicks's method and the membranes should be ruptured at once and a foot brought down. Once this is accomplished, if the patient is not already exsanguinated or suffering from shock, we can practically rest easy, using gentle, intermittent traction, not exceeding two pounds. Should, however, either of the aforesaid conditions exist, restoratives should be used at once, such as normal saline solution, morphine, strychnine, digitalin, or an ether or a whiskey hypodermic. For obvious reasons the normal saline solution cannot be given per rectum in these cases. No condition of the patient would justify a rapid dilatation or rapid emptying of the uterus, as even a slight laceration in these cases might open a large vessel at the placental site, resulting in a profuse and probably uncontrollable hæmorrhage, while the shock of rapidly emptying the uterus would be almost certain to be disastrous to the patient. I want to emphasize this here, as we all know what a temptation it is, especially in one's earlier years, in

* Read before the Toronto Clinical Society, May 4, 1904.

practice, to use considerable traction in either a foot or breech presentation. In addition to the danger of laceration, hæmorrhage, and shock, there is the difficulty of delivering the aftercoming head, if the cervix is not well dilated before the body is delivered.

After the child is delivered, the placenta and membranes should be removed at once and if the hæmorrhage continues, only one line of treatment should be adopted, as there is no time for uncertainties. The uterus should be well drawn down with a strong volsella forceps. This traction alone often controls the hæmorrhage. The entire uterine cavity, cervix, and vagina should be firmly packed with sterilized gauze. While I thoroughly appreciate the hæmostatic properties of hot water, yet the difficulty of having it at just the right temperature, in private practice, is likely to result in loss of time, for, if it is not hot enough it will rather favor hæmorrhage, while if it is too hot it will paralyze the muscles. I am convinced that if this method of treating these cases was carefully carried out, leaving the case almost entirely to nature after a foot had been brought down, or with just such light traction as might or may be necessary to control the hæmorrhage, the maternal mortality would be reduced almost to a minimum.

Now as regards the hydrostatic and pneumatic methods of dilatation, which have been so extolled by Maurer and Duhrssen, of Germany, and DeLee, of Chicago, of which the Champetier de Ribes balloon and Carl Braun's colpeurynter are probably the best, I feel that their field of usefulness is for obvious reasons practically limited to hospital practice. The only advantage claimed for them is a probable reduction in infant mortality. The same can be said of Cæsarean section either vaginal or abdominal, only the cases requiring such a formidable procedure will be very few indeed.

As regards Bossi's dilator, I mention it only for the purpose of strongly condemning its use in placenta præviæ as being most dangerous. The same is true of any metal dilator. Notwithstanding this, De Paoli records 19 cases treated by Bossi's method in which the time occupied in emptying the uterus varied from five to fifteen minutes, with a loss of one mother and three children, and he asserts that in some instances there was no dilatation at the commencement of the operation. Now, how a uterus could be competently dilated and emptied in that time with safety to a mother is, to my mind, an obstetrical mystery. Even though it were possible fully to dilate the cervix in these cases in so short a time with safety to the mother, I cannot conceive of a condition that would warrant one in rapidly emptying the uterus unless, perhaps, alarming hæmorrhage, and even that would not justify

the procedure, as the additional shock of rapidly emptying the uterus of an already exsanguinated patient would almost positively turn the tide to a fatal issue. I am sure there is no other known means by which this could be safely accomplished.

Schroeder's assertion that the physician who has least regard for the life of the child in these cases, will have the smallest maternal death rate, cannot, to my mind, be too strongly impressed on the mind, of the young obstetrician especially.

Accidental Hæmorrhage.—Here we have quite a different condition of affairs to that in placenta præviæ, for if the hæmorrhage is severe the only treatment that offers any degree of safety to the mother is a rapid dilatation and emptying of the uterus by whatever means may be at hand; having previously applied a firm binder over the abdomen, and the cervix being well dilated, ergot should be administered in full doses hypodermically, and the attendant should have everything in readiness to pack the uterus after it is emptied, providing there is post partum hæmorrhage, as there is likely to be, on account of the atonic condition of the previously overdistended uterine walls. The placenta and membranes should be removed immediately after the delivery of the child (which should be as rapid as possible). While I have never had occasion to use Bossi's dilator, yet in careful hands I could understand its being a valuable means of dilating in these cases and possessing the advantage over the various bags and balloons that it is always in working order when required.

In all these cases the patient's strength must be constantly sustained by the usual restoratives. The subsequent treatment will be that for acute anæmia and probably shock, namely, saline transfusion, lowering of the head, raising of the foot of the bed, hypodermics of strychnine, morphine, and digitalin, also hypodermics of ergot to favor uterine contraction and, if needs be, autotransfusion.

In the milder revealed cases we may safely temporize by putting the patient to bed, administering full doses of morphine, and keeping her absolutely quiet for some time after all symptoms have subsided.

Post Partum Hæmorrhage.—Speigelberg was not far astray when he said that grave post partum hæmorrhage is almost without exception the fault of the medical attendant. I think if we exclude the cases of hæmorrhagic diathesis and those from laceration, we can all pretty well endorse this assertion. The treatment, therefore, is largely preventive. However, I shall only deal with the active treatment, and this depends on whether the placenta has been expelled or not. If the placenta is still in the uterine cavity, the hæmorrhage has been extensive, and the uterus is not contracting satisfactorily, the hand should be promptly but gently introduced, gloved

of course, the placenta carefully separated, and the whole of the interior of the uterus palpated, the hand being kept in the uterine cavity until expelled with the placenta and membranes by the contractions of the uterus. This will usually control the hæmorrhage.

If on the other hand the uterus is empty when the hæmorrhage occurs, only two methods of treatment should be considered: a hot douche at 120°, or the same with acetic acid 3 per cent., or say 4 ounces to the gallon; secondly, packing with sterilized gauze. In packing, the method recommended by Henkel and Peretti should first be adopted of catching both anterior and posterior lips with volsella forceps and drawing the uterus well down as for vaginal hysterectomy. Holding it in this position will alone frequently control the hæmorrhage. If not, we have the uterus in the proper position for douching or packing.

The after-treatment is the same as recommended for the other cases of acute anæmia and shock.

The points I wish to particularly emphasize are:

First.—That in order to satisfactorily cope with any of the aforesaid conditions we must have our line of action positively decided on before we meet the case, and then make the best use of every minute, as the loss of one minute may turn the tide against us. There is no time for uncertain methods.

Second.—I have limited myself in most cases to one method of treatment, and in no case to more than two. I cannot understand our text books and obstetric teachers persisting in burdening the young practitioner with half a dozen or more methods of meeting these emergencies. It is most perplexing to the attendant, and valuable minutes are lost in uncertain methods and, I have no doubt, frequently valuable lives.

Third.—No condition of the patient in placenta prævia will justify rapid dilatation or rapid emptying of the uterus. Should evidence of shock or collapse occur, all operations should be abandoned and restoratives applied.

Fourth.—The sustaining of the patient's strength at all stages of the operation, the physician never leaving the patient till she is out of danger and always securing the assistance of one of his colleagues.

Fifth.—That morphine and strychnine hypodermically is, *par excellence*, the best possible means of combating or controlling shock in these cases.

Sixth.—To adopt no method of treatment that we are not positive will not diminish the mother's chances in the slightest degree. While I would not like to be the last to lay down the old, yet I do not want to be the first to take up the new. Unfortunately there seems to be an uncontrollable desire in a large number of members of the profession to be constantly looking for something new, and when

they get it they think they are inspired and that all other treatment has been a mistake. Would it not be more to our credit to be slow to abandon the old and to take up the new, but to rather follow Paul's advice to the Thessalonians, to prove all things and hold fast that which is good?

WELLESLEY STREET AND ROSE AVENUE.

INTESTINAL PERFORATION IN TYPHOID FEVER.

By HUGH M. TAYLOR, M. D.,

RICHMOND, VA.

Within the past two months I have been called on to operate in two cases of typhoid perforation, and to see one case of intestinal hæmorrhage, which was at first thought to be a case of perforation. It is rarely that I am able to discuss this subject with medical colleagues who cannot recall deaths in their practice, from suspected perforations which were not operated upon, and even in the newspapers we not infrequently see notices of deaths from peritonitis and perforation complicating typhoid fever. An occasional epidemic of cholera, yellow fever, or bubonic plague, that killed 50,000 people in the United States each year, would create widespread terror in medical circles and in the civic government. Every year more than 50,000 representatives of the young manhood, womanhood, and childhood of the United States alone die from typhoid fever. The United States Marine Hospital Service Report (page 1008, 1896) estimates that there are 500,000 cases yearly and 50,000 deaths. Victor Vaughan, in a recent address, says there die in this country every year from typhoid fever alone not less than 50,000 people. These reports are made up from the reports of the larger towns and cities in which mortality rates are compiled. They do not include the thousands of cases which occur in the country, of which no report is made. Many more than 500,000 deaths, obviously, occur from typhoid fever in the United States each year and, assuming a death rate of ten per cent., many more than 50,000 deaths ensue. Preventive medicine has accomplished much in the field of typhoid fever; it has yet much to accomplish. It is stated that three per cent. of typhoid fever patients die from intestinal perforation; three per cent. of 500,000 is 15,000; more than 15,000 deaths from typhoid perforation in the United States each year! Some writers have estimated that not more than ninety-five per cent. of typhoid perforations will die without operation; others place the death rate at ninety-nine per cent. Possibly a perforated cæcum or appendix from a typhoid ulcer, may result in a circumscribed abscess; in

fact, this is not infrequently the case. More than eighty per cent. of complete perforations occur in the last eighteen inches of the ileum, and I fully agree with those who think that in such cases we may expect a mortality of one hundred per cent. This being true, more than 15,000 cases of typhoid perforation should be operated in each year in the United States. In 1900, Dr. Keen could tabulate only the reports of 158 cases operated in. In April, 1903, Frank reports but 352 cases operated in the world over. Of course, there are unreported cases operated in, but they are comparatively few in number. Contrast this statement with the plea that more than 15,000 cases should be operated in every year in the United States alone, and you have my excuse for persistently bringing this subject before you for discussion. As a matter of fact it embarrasses me to bring my statistics before you; they compare so unfavorably with the achievements of other surgeons in this field, some of which I shall present to you to sustain the claims for operative intervention in all cases of typhoid perforation. I am optimistic to an extreme as to the value of surgical aid in typhoid perforation, not from my own experience, but from a study of the opinions and the results of others. My cases include seven operations for complete perforation of the lower portion of the ileum, with but one recovery. It is not a difficult matter to explain my high death rate. My medical friends have not solved the problem of how to make an early diagnosis of perforation. With but two exceptions, my cases were eleventh hour cases, and several of the patients were practically moribund when operated upon. I feel it my duty, as I think it is the duty of every surgeon, to give even these forlorn cases the only chance left. Greig Smith, in discussing this question, pertinently asks: Who can always tell when a patient is moribund? In all but two of my cases I was not called upon to operate until after the first twenty-four hours, and in all, widespread, so called general, peritonitis was conspicuously present.

What has surgery accomplished in the treatment of typhoid perforation? "Twenty years ago," says Dr. Osler, "we would fold our hands and murmur that all was over," when we were brought face to face with a case of typhoid perforation. Recently, Dr. R. G. Le Conte reports three consecutive successful cases. Dr. W. D. Haggard, Jr., reports three cases and three recoveries; one hundred per cent. What a stimulus! And more than 15,000 cases in the United States to operate on each year! Certainly the profession at large did not appreciate the importance of this subject until the advent of Dr. Keen's well known

paper in 1901, in which he showed in 158 cases a mortality of twenty-three and four tenths per cent., and this in spite of the fact that it included late operations in many instances, and those by inexperienced operators in not a few. Since 1900, our confidence in operative intervention has, with cause, steadily grown; due notably to statistics from Dr. Warren and Dr. Cobb, twenty-five per cent.; Dr. Osler, thirty-seven and five tenths per cent.; Dr. Cushing, forty-one and six tenths per cent.; Dr. Armstrong, thirty-seven and five tenths per cent. One operator, Eschner, has had the proud distinction of saving fifty per cent.; fourteen cases with seven recoveries. More than one series of forty per cent. of recoveries has been reported, and it is confidently predicted that early diagnosis and operation, to prevent septic peritonitis, will result in the saving of from fifty per cent. upwards; fifty per cent. of more than 15,000 cases is an indication of the possibilities of surgery in this field, in the United States alone.

By far the most important phase of this subject is the early diagnosis, as it implies preventive surgery. How to make an early diagnosis, and how to treat the late sequences of typhoid perforation may well set the limits to this paper. The former, the early diagnosis, is the more important, for a greater number of early diagnoses means fewer late cases, with gross intraperitoneal lesions, to operate in. The diagnosis of the late cases is easily made; we have the usual symptoms of general suppurative peritonitis. The answer to the first question must be solved to a large extent by the general practitioner. As a rule, only the family physician has the opportunity to study the initial symptoms of perforation. Certainly, my experience sustains the assertion that a surgeon is very frequently not called in to see the case until the gross consequences of perforation are pronounced. I cannot too emphatically agree with those who have urged cooperative study in all suspicious cases by the general practitioner and the surgeon. A greater number of cases is undoubtedly being recognized, but a vast number is not recognized. If we keep in mind that in three per cent. of all cases of typhoid fever we are called upon to treat, perforation occurs, we shall watch more intently for the first symptoms. Some sage has remarked that the matter of diagnosis is largely guess work, but adds that the practitioner who is looking for a trouble and has its symptomatology uppermost in his mind will more frequently make the early and correct diagnosis.

In typhoid perforation, as in many intraperitoneal, morbid conditions, we may expect to meet with typical and atypical cases. In some, the clinical picture will be unmistakable. In others, it

will be blurred beyond recognition. If, when called to a case, we are told that it has run an uneventful course, that there have been no pronounced abdominal symptoms, no mental confusion, or delirium, to mask an expression of symptoms, that the patient was, up to a given time, comfortable, and, while having an action of the bowels, was taken with sharp continued pain, tenderness, and muscular rigidity; perhaps with chill, reduced temperature, increased pulse rate, and vomiting, symptoms of shock; we have a chain of evidence pointing to perforation, as closely linked as that upon which we commonly have to rely in most acute peritoneal infections. A large majority of the cases I have seen have presented a clinical history as clear as that indicated by the above described group of symptoms.

On the other hand, it is easy to see how such symptoms may be masked if the patient is delirious, if there is abdominal distention and gastroenteric disorder, and if there have been daily marked variations in pulse and temperature. Fortunately, in my experience, a large number of typhoid cases are atypical in type and the gross symptoms which would mask the symptoms of perforation are probably in the minority. It should be borne in mind that other conditions than perforation may, during the existence of typhoid fever, give rise to symptoms of local and general peritonitis. Incomplete perforation may, and I think often does, give rise to local peritonitis and adhesions. In one of my cases, a preperforative abscess formed with later rupture and flooded the peritoneal cavity with pus and intestinal debris. The lower portion of the ileum entered into the formation of the abscess wall, and in this portion of the ileum was a large perforation. I do not believe that adhesions occur after perforation of the small bowel, but I do think that it is not infrequent in the preperforative stage, and that it possibly saves many lives. It is also essential to take into consideration the occurrence of acute cholecystitis, appendicitis, and the infection, suppuration, and discharge of the mesenteric and other intraperitoneal glands, and also the possible thrombosis of intraperitoneal blood vessels. While these are possibilities relatively infrequent, perforative cholecystitis and thrombosed mesenteric vessels may give rise to acute symptoms of local and general peritonitis.

I have seen a number of cases of acute cholecystitis occurring during the course of typhoid fever. In several instances, I have mistaken typhoid fever in its incipency for appendicitis, and I have also seen the two conditions coexist. I have not, however, seen perforative peritonitis during typhoid fever due to any cause, except ty-

phoid perforation. Usually the differentiation has to be made only between typhoid fever and the conditions mentioned. In exceptional instances, an unrecognized, ambulatory case of typhoid fever may have perforation, and the only symptoms presented will be those of perforative peritonitis.

The symptoms of intestinal hæmorrhage may at first simulate those of perforation, and this is notably so when the conditions coexist. A case recently seen with Dr. E. J. Moseley, Jr., and Dr. William S. Gordon, presented slight symptoms of abdominal pain, profound collapse, reduced temperature, increased pulse, anxious expression, and pinched features, and this was followed in six or eight hours by reaction. I was at first misled, but there was in this case an absence of the acute, lasting pain, tenderness, and muscular rigidity. Later on, progressive improvement and large bloody stools cleared the obscurity in the diagnosis.

No feature in the diagnosis is more important than the sudden transition from the quiescent condition to one evincing acute intraperitoneal invasion, and no symptoms of the last condition are more uniform than acute, lasting pain, and tenderness with muscular rigidity. With these, we may or may not have the usual symptoms of shock. The limits of this paper will not permit me to analyze in detail the relative value of pain, tenderness, rigidity, vomiting, hiccough, reduced temperature, increased pulse rate, distention, liver and flank resonance, inhibited peristalsis, the value of blood count, blood pressure, the injection of fluids and air into the suspected peritoneal cavity, etc. Usually writers have confused preperforative symptoms, symptoms coming on immediately after perforation, and the later symptoms, those expressive of acute widespread peritonitis. I agree with those who classify the symptoms into three groups: (1) the preperforative; (2) the early or immediate symptoms of perforation; (3) the late; those of septic peritonitis. These last are really not symptoms of perforation, but are its inevitable sequence; virulent, widespread peritonitis.

In the diagnosis of perforation, we must not in its incipency expect an unbroken chain of evidence. Missing links are found in the symptomatology of acute gastric bile tract and appendicular infection. If there are pain and muscular rigidity in the right iliac fossa, a majority of surgeons will operate, confidently expecting to find an appendicitis. Clinicians, who have had the largest experience in dealing with typhoid perforations, dwell upon the danger of delay. Dr. Osler writes: "as typhoid patients bear operation

well, it is better to err in favor of surgery than to let valuable time be lost in waiting for further confirmatory evidence; and again: in doubtful cases, give the patient the benefit of the doubt and operate"; Dr. Cushing says, "when reasonably in doubt, explore"; Richardson: "operation should be done when perforation is suspected rather than demonstrated"; Greig Smith: "at the worst, happen what may, the patient can be in no more deplorable condition than before operative interference was carried out and I would plead for an attempt to reduce a mortality of one hundred per cent." Early operation lessens the amount of surgery called for, is conservative, and life saving.

The technique of the early operation is very simple and implies a median or right lateral incision (I prefer the latter, as it gives easier access), suturing the perforation, and cleansing the soiled area, and I agree with those who maintain that fifty per cent. to sixty per cent. of cases thus treated should recover. The best technique in eleventh hour cases is an unsolved problem. How best to treat widespread intraperitoneal infection from any cause is an open question. In this, as in other acute intraperitoneal infections, the key to success depends upon getting into the abdomen early and out of it just as quickly as is consistent with complete work. It is sometimes as hard to know when to get out of the abdomen at the right time as it is when to get in. Complete work implies that which will save the greatest number of patients. A conception of what should be regarded as complete work varies very widely. Good men are not willing in general infection to stop short of evisceration and the use of gallons of water in flushing; others are content to wipe out the infected cavity. Still others contend that if we trust more to the recuperative powers of the peritonæum after removing the focus of infection, we shall get better results. Still others, notably Dr. J. B. Murphy, think prolonged irrigation, wiping, and prolonged anæsthesia shock to such an extent that the patients do not rally. Dr. Murphy recently reported sixteen bad cases (one a typhoid perforation), in which he simply removed the focus of infection, instituted pelvic drainage, and trusted to the peritonæum to do the rest. Fifteen of these cases ended in recovery. Fowler saved sixty-two per cent. Escher thinks that suturing of perforation produces immediate stenosis of the bowel and, as I have stated, he contents himself with simply finding the perforation, and suturing the torn segment of the bowel into the abdominal incision. His report of fourteen operations and seven recoveries is the most encouraging I have seen. Greig Smith

uttered a truism very pertinent in connection with Escher's method of treating typhoid perforations: better a live patient with a faecal fistula, than a dead patient with an air and fluid-tight anastomosis. I live in the hope that some of the pathfinders in surgery will soon blaze a way out of this horrible wilderness, which the uninitiated may successfully follow in the treatment of widespread intraperitoneal infection. In the treatment of eleventh hour cases of general peritonitis from typhoid perforation, I have eviscerated and irrigated and I have irrigated without eviscerating. I have used multiple gauze and tubular wick drainage, anterior, posterior, and lateral, after wiping. I have followed as best I could Fowler's technique. In one recent case, operated in thirty-six hours after perforation, under local anæsthesia upon a practically moribund patient, I followed Escher's technique, and in my last case, operated in twenty-four hours after perforation, I only sutured the perforation, put a large tube into the rectovesical pouch, and placed the patient in Fowler's position. With few exceptions, my patients have all died. I can see nothing but the deepest gloom when I view widespread, intraperitoneal infection from typhoid perforation, especially in contrast with the brilliant results from the early operation. I shall continue to deny no one, however seemingly moribund, the only hope offered. I plead for an early diagnosis, and operation whenever and wherever a case of typhoid perforation occurs. Escher saved fifty per cent. Is his technique within the scope of the general practitioner? Two of my recent graduates have operated successfully in the backwoods of West Virginia. I advocate the closest cooperative work in this, as in many conditions, between surgeon and physician. If, however, the victim of typhoid perforation cannot be gotten to the surgeon, or the surgeon to the victim, I aver that the general practitioner has no more right to shirk the responsibility of operating, and thereby abandon his patient to inevitable death, than he would have in a case of strangulated external hernia. There is a possibility of a saved life by a faecal fistula in the case of strangulated hernia; but, as far as we know, it is death or operation in typhoid perforation. Dr. Victor Vaughan, in a recent address, says typhoid fever "is essentially a disease of the rural districts." Thousands of patients can secure only the services of the country practitioner. Don't stop to think of sepsis; it can always be secured, but even if it could not, the general practitioner's hands cannot possibly be as foul as the peritoneal cavity, with faecal matter pouring into it. Such a condition cannot be made worse. Look

for it and it will be found. Operate by Escher's technique and some patients will be saved. A case abandoned at any stage is a reproach.

LUMBAR PUNCTURE: ITS VALUE IN DIAGNOSIS AND TREATMENT.*

By EDGAR P. COOK, M. D.,

MENDOTA, ILL.

Although puncture of the spinal meninges was first employed by Quinke, in 1890, for the relief of the intracranial pressure in tuberculous meningitis, general attention was not attracted to the procedure until 1895, when Furbinger reported the striking results obtained in a series of cases in which he had resorted to lumbar puncture for diagnostic rather than therapeutic purposes. Since then the field of application of lumbar puncture has been greatly extended, and at the present time it has become an established operation for diagnosis and, in less degree only, a recognized means of treatment.

The technique of spinal puncture is simple and the procedure when aseptically performed is practically free from danger. Pfaundler reported two hundred lumbar punctures without a single bad result. In one case only of his series was there collapse, due to the removal of an excessive amount of fluid. Northrup noted no ill effects in fifty cases. Gumprecht, in 1900, collected fifteen cases of sudden death following lumbar puncture and added two cases of his own, but he failed definitely to connect the untoward results with the operation itself. Those observers who have had the largest experience with the operation agree that when properly performed it is harmless.

As a result of the extended use of lumbar puncture careful studies have been made of the cerebrospinal fluid *intra vitam*. These investigations have thrown a flood of light on many hitherto obscure problems in the pathology and ætiology of affections of the cerebrospinal meninges and have modified our views regarding certain acute and chronic diseases in which these structures are involved. Although the diagnostic value of lumbar puncture far exceeds any therapeutic value yet discovered for the procedure, it is nevertheless a welcome addition to therapeutics in a field where the resources at our command are yet very meagre.

The normal cerebrospinal fluid is perfectly clear. Sicard, Widal, and others have shown that in health it contains scarcely any cellular elements; there is an entire absence of polymorphonuclear leucocytes and the small mononuclear

cells or lymphocytes are very scanty if present at all. Albumin is present as a faint trace (0.02 per cent to 0.04 per cent.), and there is no fibrin. Sugar is normally present, but, according to Pfaundler, sugar disappears in acute inflammatory disease of the meninges. This observation, however, lacks sufficient confirmation to be of diagnostic weight. The amount of fluid allows of no definite conclusions, except that a great amount of fluid as shown by very high pressure is most frequently met with in tuberculous meningitis. An increase in the albumin (more than 0.05 per cent.) in the absence of blood, points to tumors or inflammatory disease, and a considerable excess of albumin in a clear fluid, according to Pfaundler, is almost a certain sign of tuberculous meningitis.

Wentworth states that in meningitis the withdrawn fluid is invariably cloudy. The degree of cloudiness, however, depends on the number and character of the cells in the meningeal exudate. It is sometimes so slight as to be detected with difficulty. While, therefore, marked changes in the gross appearance of the fluid are of suggestive value, reliance should be placed only on a complete microscopical and bacteriological examination. The necessity of thorough examination is emphasized by the experience of Barr, who reported cases of purulent meningitis in which puncture showed a clear fluid. A cardinal rule in estimating the results of lumbar puncture has been insisted on by Hand, who declares that positive results only are of diagnostic value; it is unsafe to draw any conclusions from negative findings. For example, although the demonstration of tubercle bacilli in the fluid constitutes a positive diagnosis of tuberculous meningitis, failure to prove their presence does not necessarily exclude the disease. Occasionally fluid may not be obtained. This failure is usually due to a faulty technique, but rarely it may result from the thick, wax like character of the exudate, as in a case mentioned by Packard, in which the diagnosis was proved by post mortem examination.

An admixture of blood in the spinal fluid may be accidental from the operation. Such an explanation is excluded when repeated punctures show persistence of the same amount of blood. The stage of the disease in which the puncture is resorted to must always be considered. Puncture made late in the attack may fail to show changes which were pronounced at an earlier period.

The bacteria most frequently found in the cerebrospinal fluid are the tubercle bacillus, the meningococcus intracellularis of Weichselbaum, the pneumococcus, and the streptococcus and staphy-

* Read at the meeting of the Illinois State Medical Society, Bloomington, Ill., May 18, 1904.

lococcus. The tubercle bacillus can usually be demonstrated in the sediment by the ordinary staining methods. By direct examination of the cover slips in this way, Pfaundler found tubercle bacilli in 91 per cent. of the cases where they were present. Rarely, inoculation experiments may be required to make a diagnosis in tuberculous meningitis on account of the scarcity of the micro-organisms. Cultures are usually necessary for the proper identification of the meningococcus, pneumococcus, and ordinary pus cocci. As pointed out by Councilman, the meningococcus may vary greatly in numbers. Usually it is readily found and in abundance. When present in small number it may be missed on the cover slips, and even when present in large number the culture tubes may show only one or two colonies. The demonstration of the meningococcus is positive proof of the existence of cerebrospinal meningitis of the epidemic type. In fifty-five cases of meningitis in which lumbar puncture was made, Councilman found the meningococcus in thirty-eight cases. He states that the cocci are most constantly present early in the disease, i. e., at a time when the diagnosis is most difficult from the symptoms alone. The identification of the meningococcus is also important from a prognostic standpoint, as these are the only cases in which recovery is likely to occur. Osler states that the pneumococcus cases are invariably fatal.

Cytodiagnosis, or the study of the cellular elements in the fluid, has yielded some interesting and valuable results. As already stated, normal cerebrospinal fluid contains few or no cells. In diseased conditions, leucocytes of one type or another may appear in greater or less abundance. The number of cells will determine the degree of cloudiness of the fluid, while the type of cells which preponderates will furnish information as to the nature of the infective agent. Generally speaking, the presence of the large polymorphonuclear leucocytes is indicative of an acute microbial invasion of the meninges, while the small mononuclear lymphocytes are found in the sub-acute and chronic affections, especially in the tuberculous form.

In purulent meningitis there is a polymorphonuclear leucocytosis, and the lymphocytes are scanty. A lymphocytosis is met with in tuberculous meningitis. The explanation of these findings is interesting. The polymorphonuclear leucocytes are cells of the highest phagocytic capacity, and therefore appear in the onset of an acute bacterial infection. The lymphocytes, being of inferior resisting power, occur in the sub-

acute inflammations of which tuberculous meningitis is a good example.

Lymphocytosis of the cerebrospinal fluid has also been noted in certain chronic toxic affections, and especially in tabes and general paralysis. In the latter affections, lymphocytosis is the rule, positive results having been found in 116 of 125 cases of these two diseases, which were reported to the Neurological Society of Paris, in March, 1903.

Care is necessary, however, in cytodiagnosis. A case reported by Pighini illustrates an interesting fallacy. A diagnosis of a tuberculous process was made where subsequent recovery suggested an error in diagnosis. He explains the mistake thus: Cytodiagnosis was made too late, a lymphocytosis having already replaced the initial polymorphonuclear leucocytosis excited by the bacterial invasion. Widal also cites an interesting case which, while apparently showing the uncertainty of cytodiagnosis, proves its accuracy. A patient with general paralysis developed a polymorphonuclear leucocytosis due to an apoplectic attack. A lymphocytosis reappeared with the subsidence of the congestive symptoms.

Cytodiagnosis of the cerebrospinal fluid has been attempted in some forms of mental disease and in a number of nervous diseases, but with the exception of tabes and general paralysis, no definite diagnostic conclusions are justifiable. The cerebrospinal fluid has been found normal in Friedreich's ataxia, cerebellar hereditary ataxia, multiple sclerosis, syringomyelia, polyneuritis, poliomyelitis, epilepsy, and neurasthenia. Positive changes have been noted in syphilitic meningomyelitis, lead paralysis, herpes zoster, and in some cases of chorea, but further observations are necessary to decide the exact value of the findings.

In the diagnosis of the intracranial complications of ear disease, lumbar puncture may afford valuable information. Schwartz, of Halle, has satisfactorily employed the method in his clinic for several years. He says that normal clear fluid excludes diffuse purulent meningitis in cases of otitis presenting intracranial complications. Cytodiagnosis offers much aid in the diagnosis of suspected purulent meningitis and tuberculous meningitis complicating otitis. A considerable increase in the amount of spinal fluid in these cases, according to Schwartz, points to the occurrence of sinus thrombosis.

The field of usefulness of lumbar puncture in treatment is as yet limited. Naturally it has been employed most frequently in the various forms of

meningitis, but with variable results. Hitherto the treatment of meningitis has been merely palliative or symptomatic. Lumbar puncture is a remedial measure which theoretically at least is reasonable. The symptoms of meningitis are due chiefly to the toxæmia and the mechanical effects of the increased intracranial tension. It is rational, therefore, to conclude that the withdrawal of a considerable amount of inflammatory exudate containing the specific germs in large numbers should exert a favorable influence on the course of the disease. Clinical experience has shown that lumbar puncture is of value in the treatment of meningitis, but it is to be remembered that in a disease like cerebrospinal meningitis, which is apt to present occasional remissions of symptoms and signs, very great care is necessary in drawing conclusions regarding the value of any single remedy. Koplik has reported five cases of meningitis with four recoveries, the fatal case occurring in a child aged eight months. Relief of the symptoms due to the pressure and toxæmia followed the tapping, which was repeated according to the indications in each case, most of the cases being tapped three times in the course of the disease. In view of the fact that we have no specific remedy in cerebrospinal meningitis, I believe that every case of the disease should be given the benefit of repeated lumbar punctures, because this line of management is rational and has shown the best results so far recorded.

Bochard reports several cases of head injury in which the escape of a small amount of the cerebrospinal fluid aroused the patient from stupor and hastened recovery. Marie and Gullian noted relief of headaches of syphilitic origin, following lumbar puncture. Recently Babinski has recorded eight cases in which lumbar puncture was resorted to for the relief of symptoms incident upon chronic aural catarrh. The patients were invariably relieved of the subjective noises and the deafness was markedly improved, in some cases permanently. In chronic hydrocephalus lumbar puncture produces temporary improvement, but it is not curative. This is the conclusion arrived at by Raczyński after testing the method in twenty-six cases of hydrocephalus.

The withdrawal of a small amount of cerebrospinal fluid by lumbar puncture preliminary to the subarachnoid injection of the antitetanic serum in tetanus has been frequently done of late. It is the most effective simple method of exhibiting the antitoxine in this disease. In July last, I saw a case of acute tetanus in a boy of twelve years on the fourth day of the attack, which followed a pistol wound of the palm of the hand. Twenty c.c.

of cerebrospinal fluid were removed by lumbar puncture and 15 c.c. of antitoxine injected into the spinal canal. No effect was produced on the course of the disease, which rapidly terminated fatally.

The rôle of lumbar puncture in the method of subarachnoid cocainization for anæsthesia is chiefly of surgical interest.

In conclusion, I wish to present two illustrative cases in which lumbar puncture was employed:

CASE I.—Young negro, aged 16 years, first consulted me April 12, 1902, giving a history suggestive of incipient lung disease. Examination was entirely negative, except for a few faint râles in the right apex after coughing. The lymphatic glands were normal. Temperature, 100.6° F.; pulse, 116; respirations, 18. Sputum examination was twice negative. Repeated examinations of the sputum, which was scanty and obtained with difficulty, finally showed a very few tubercle bacilli.

On May 1st, careful examination of the chest failed to reveal any physical signs of disease. Temperature was 100.8° F.; pulse, 120; respirations, 18. Two days later there was sudden onset of vomiting, which persisted for forty-eight hours, and was followed by severe headache, chiefly frontal. Pain developed in the back of the neck and there was rigidity of the cervical muscles. The patient remained mentally clear, but was very restless, rolling about in bed. The pulse fell to 52, and was full and regular, but was accompanied by a subfebrile temperature. The urine showed a trace of albumin, several hyaline casts, and a few red blood cells. No ocular changes were noted. Moderate delirium slowly developed, gradually passing into coma. The pulse remained slow, finally rising to 84, with normal temperature and respiration just before death, which occurred in coma, May 16, 1902. Lumbar puncture was made post mortem and 15 c.c. of clear fluid were removed. A few tubercle bacilli were found in the centrifugated fluid, thus confirming the clinical diagnosis of tuberculous cerebrospinal meningitis supervening on incipient pulmonary tuberculosis. Cultures on blood serum were negative.

CASE II.—School girl, aged 10 years, was seen in consultation February 6, 1903. The onset of attack was sudden two days previously with headache and vomiting. Examination showed the pulse to be 92; temperature, 104° F.; respiration, 32, irregular, of Cheyne-Stokes type. Patient lay in coma on the left side with the limbs drawn up; head retracted and muscles of neck rigid; herpes labialis marked; eyes and ears negative; no facial paralyses; heart, lungs, and skin normal; Kernig's sign distinct. There was slight paralysis of right foot, producing inversion and flaccidity. The urine contained considerable albumin and a few hyaline casts. Lumbar puncture was performed and 20 c.c. of clear fluid were withdrawn. Cover slips were negative. Cultures on Loeffler's blood serum showed diplococci in pure growth, resem-

bling morphologically the meningococcus. Following the lumbar puncture there was slight but gradual improvement in the symptoms. The coma persisted for nearly two days, gradually disappearing. On February 11, the temperature was normal and convalescence established. Subsequent recovery was rapid and there were no sequelæ. Aside from the lumbar puncture the treatment was purely symptomatic.

ELECTRICITY IN OTOTOLOGY.

By J. J. RICHARDSON, M. D.,

WASHINGTON, D. C.

Electrical energy in its various forms has not been employed in the diagnosis and treatment of aural effusions to the same extent that it has been in those of other regions of the body. The subject has been practically ignored by some of our best known writers on otology. In reviewing the literature, however, we find it has been employed in a way since the time of Volta. More or less material is met with, but from the standpoint of a specialist the communications are not of much value. In most instances they consist of reports of cases by electrotherapeutists, who show a lack of knowledge of aural affections. Again, we find reports of cases treated by *electricity* without any reference to the kind of current employed, its intensity, or manner of application. All these factors naturally vitiate the value of such reports to the specialist. I am not an enthusiast, who claims electricity to be a panacea for all diseases, but after careful experimentation and observation, I am convinced that it at least possesses great possibilities along certain lines. The more I employ it the more I appreciate the great benefit that may result in the future from its scientific application. I know from practical experience that we can by its employment in one form or another, (1) stimulate weak muscles, (2) relieve pain, either by direct action of the current or by the cathartic application of anæsthetics, (3) stimulate absorption of inflammatory exudates, (4) overcome stenosis or complete strictures, and, (5) at times revive nervous activity. In order to get satisfactory results it is necessary to have not only a knowledge of the physiology and pathology of the parts we are treating, but a thorough understanding of electrophysiology and electrophysics. The apparatus employed must be of the highest standard and under perfect control when applying the different currents to such a delicate organ as the human ear. Without these, we are assuming a risk which is unjustifiable and may inflict injury upon our patients instead of affording relief. For example in the application of galvanism, the polarity of the current is of the greatest importance. The negative pole will often do good while the application of the positive may

be painful and even injurious. In other instances the strength of the current must be accurately measured. A mild one will frequently relieve or cure conditions where a stronger one would aggravate them. This is especially true in some forms of tinnitus. An accurate milliamperemeter should always be used, notwithstanding the statement made by Politzer that the rheostat and galvanometer, indispensable for physiological experiments, are superfluous for therapeutic purposes. We do not administer powerful drugs without knowing their dosage. The same principle applies exactly to the use of galvanism without a meter, as only by its pointings have we a means of knowing the amount of energy passing or the patient's resistance. This resistance is frequently different in different individuals and is also modified by pathological changes.

The action of electricity on the normal auditory nerve produces an interesting phenomenon. The sensation produced is described differently by different persons, but is always identical in the same individual. In one it resembles the ringing of bells, in others a hissing or buzzing sound, while in still others it produces musical tones of various intensities. This is the normal reaction of the acoustic nerve and the constant current alone should be used in investigating this excitability. The series of successive shocks produced by the interrupted current is of too short duration to produce any distinct sensation. The intensity of the current necessary to produce these reactions varies according to the polarity, and is altered by pathological changes in the ear. With the negative pole at least four, and with the positive six to eight milliamperes are necessary. When the negative pole is applied to the ear and the current abruptly established, a clapping noise is experienced which continues a little during the passage of the current and produces a kind of whistling sound, or a sound resembling the buzzing of insects, of boiling water, or wind. This auditory sensation disappears, although the current may continue. There will be no sensation while the current is interrupted. On the application of the positive pole there is no auditory sensation at the time the current is applied, or during its passage, unless it be prolonged, when a feeble crackling sound may be experienced. More or less serious difficulty is encountered in bringing about this normal excitability, on account of the auditory nerve being so deeply placed and surrounded by its bony envelope and labyrinthine fluid. It is much less accessible than the other nerves of that region, so that often before obtaining the special auditory reaction, other effects are observed which interfere with the test. Excitation of the auriculotemporal nerve may cause some pain and excitation, and of the facial,

muscular facial contraction. Stimulation of the chorda tympani is especially difficult to avoid and is followed by incessant efforts at deglutition and an increased amount of saliva. I have frequently observed cough and, in one case, a sort of vocal oppression and hoarseness which continued several hours. These effects are doubtless due to the stimulation of the auricular branch of the pneumogastric. The most disagreeable phenomena that may be produced are those due to excitation of the brain. Giddiness, vertigo, paleness, nausea, and tendency to syncope may be observed and it is important to know of these phenomena in advance and also to bear in mind that they depend above all upon a sudden variation of the intensity of the current. The current interruption must be gradual and not abrupt if we wish to avoid these unpleasant symptoms. The acoustic nerve reaction is a valuable clinical test and ranks along with the tuning fork and Galton's whistle. Gradenigo goes so far as to maintain that electrical examination must play in otology the same part that the ophthalmoscope does in ophthalmology.

The normal excitability of the nerve is modified by pathological conditions. In perforations of the tympanum and in the majority of labyrinthine diseases it is observed that very feeble currents, one to two milliamperes or even a fraction of a milliampere, will often produce the indicated reaction. When the stronger currents are employed the noises last often during the entire passage of the current. The most established fact is the association of hyperæsthesia and hyperæmia of the nerve. It never exists in non-inflammatory diseases of the ear. Diminished excitability or electric torpor at times exists and is observed in cases of impacted cerumen and in diseases of the labyrinth with violent tinnitus. It has been demonstrated by Rohrer to exist in all cases of auditory neuritis, either primary or secondary to cerebral hæmorrhage, tumors, or softening. We may have conditions existing analogous to certain neuritides of motor nerves where galvanic excitability is increased at a certain period and becomes gradually less—the torpor being the final end of hyperexcitability.

There are different methods of applying electricity to the ears. The one which I employ for both the galvanic and faradaic currents, when both ears are to be acted upon, is a bifurcated intraauricular electrode, the metallic ends of which I cover with moist absorbent cotton. For the indifferent pole, an ordinary sponge electrode is placed in the hand or over the nape of the neck. I frequently apply it to the Eustachian tube by introducing a hard rubber catheter in the ordinary way, and passing through it a metallic bougie electrode, and place the other

electrode over the mastoid region. In this way it acts directly on the muscles of the tube, which at times lose their normal tonicity, and it also stimulates the circulation of the parts. For this purpose I usually employ the faradaic current, which produces a sort of tingling sensation, but no vertigo or other symptoms of cerebral irritation.

The active pole for therapeutic purposes should almost always be the positive, unless electric torpor exists, as it is the sedative, decongestive one. The negative pole, which we employ in studying the auditory nerve excitability, acts in the inverse sense. With the faradaic current the polarity is unimportant.

In the distressing symptom *tinnitus*, which exists in so many of the aural diseases of adults, electricity will frequently be beneficial where other forms of treatment have been of no avail. It is the misfortune of us all to meet with cases of deafness with this symptom and where the patients state that if the noises in the ear could only be removed or lessened, they could get along well enough. It is in this class of cases where the ordinary treatment of inflation, Eustachian and middle ear modification, and where the nasopharynx and nasal cavities have been attended to and no improvement has followed, that electricity offers some encouragement. A fair percentage of the patients will be greatly benefited and one occasionally cured. When the tinnitus is of labyrinthine origin, or due to chronic inflammatory changes in the middle ear, the constant current is the one most employed. One to three milliamperes are sufficient and should be allowed to pass from six to ten minutes. Where there is ankylosis of the ossicles, the interrupted current has been more satisfactory in my cases, although it has not been used to the same extent as the constant current. The good effects are due to its mechanical action on the adhesions and to stimulation of the circulation and of the weakened muscles of the middle ear.

True strictures of the Eustachian tube are of rare occurrence, but when they do exist they are best treated by electrolysis. The galvanic current is utilized for this purpose. A hard rubber or silver catheter, properly insulated with rubber up to its point, is introduced and a small gold bougie is passed through the catheter and up to the point of constriction in the tube. The object is readily recognized; the bougie acts as the active electrode. It is to be attached to the negative pole of the battery, the current turned on slowly, and three to six milliamperes are to be allowed to pass. After six or eight minutes, by a gentle pressure on the bougie it will be felt to pass the softened stricture. The operation is a little painful and for a few days following there will be an increased amount of deaf-

ness and ringing and fullness in the ear. On the third day I usually pass a celluloid bougie, and at the same intervals of three or four days for two or three weeks. The dispensing electrode is held in the hand in preference to the mastoid region, or over the neck when there will be less tendency to cerebral irritation.

Complete success, by electrical treatment, of deafness either of tympanic or labyrinthine origin, is of rare occurrence. I do not recall any cases that I have treated where the hearing was greatly improved, except those naturally resulting from the diminution of the subjective noises. Hysterical deafness, like hysterical aphonia, is best treated by the faradaic current. Pruritus of the auricular canal, which is so distressing at times, is often benefited by this form of treatment. In neuralgic otalgia the interrupted current is very efficacious, when applied by means of an intraauricular electrode. Cocaine applied to the ear acts very incompletely, but its anæsthetic effect may be aided by the action of the constant current. This cataphoric process is utilized in producing anæsthesia of the tympanic membrane and external canal for slight operative procedures. The auricular canal is filled with a 10 per cent. solution of cocaine and a mild current allowed to pass for five to ten minutes when anæsthesia ensues. This same process has been utilized by some with various drugs as a means of curing deafness, but I have had no personal experience along these lines and the results published are not encouraging. The positive pole should be in contact with the fluid, and the negative applied over the neck.

1016 FOURTEENTH STREET, N. W.

Legislation Against Mosquitoes.—Assemblyman Wilsnack, of Queens county, on February 10th, introduced a bill in the New York legislature providing for the appointment of a commission, consisting of the State commissioner of health, the State engineer and surveyor, and the city commissioner of health of New York city; the engineer of the board of estimate and apportionment, of New York city, and six other members to be appointed by the Governor, to examine into the condition of the marshes at Arthur Kill, on Staten Island, and Greater Newark and Hackensack, N. J. The commission is to report to the next legislature its recommendations as to the best method of getting rid of the mosquito evil in its breeding places. The New York State Commission is authorized by the Wilsnack bill to cooperate with a similar commission to be appointed by the New Jersey legislature, or with a commission to be appointed by the Federal government. At present the Long Islanders try to get rid of the mosquitoes by burning out the marshes, but they have no lasting relief.

RETRODISPLACEMENT OF THE UTERUS.

By HELEN HUGHES, M. D.,
MANKATO, MINN.

The importance of this disorder among the diseases of women is evidenced by the number of methods that have been exploited for its cure, none of which has been so satisfactory as to close the subject.

Two methods have been evolved after much study and debate, which if used in accordance with their indications afford us a very successful treatment for many cases. These methods are support from below, including the different forms of pessary during the time that the natural supports are recovering themselves, and support from above by various operations. The results would be more satisfactory if a correct knowledge of each case was obtained, and the choice of methods made according to the conditions.

No one can be too rigid, too careful, or too painstaking in the examination of the pelvic organs. Within the last year I saw a woman who had an abortion, repeated hæmorrhages, and lastly was subjected to a curettage, and all this time she was under the care of a reputable physician who had failed to discover that the uterus was involved in a growth that afterwards proved to be malignant.

A thorough pelvic examination requires time and patience; what we fail to discover the first time we may observe in a second, or third, examination when the patient has become accustomed to our manipulations. We have no right to give an opinion or begin a line of treatment until we have made ourselves perfectly familiar with the condition of the pelvic organs, and this is very difficult, especially in the young, the rigid, the fat, and the sensitive, but that it is difficult is the very point I want to make. Many cases require repeated effort, but we have the same obligation to make a correct diagnosis for our difficult cases as for our simple ones.

When the uterus is retroverted it is often impossible to outline the tubes and ovaries by the vagina, but a very thorough examination can be made by drawing down the cervix with a pair of long artery forceps and then exploring by the rectum; in this way the posterior uterine ligaments are avoided.

In restoring a uterus to its original position or as near that position as we possibly can, we should keep in mind its natural supports and the part each plays in sustaining it in that floating, movable, yet secure position which is natural to

it. Only two pairs of ligaments possess muscular fibres, the round and the uterosacral; these fibres are prolongations from the muscular coat of the uterus, the most highly contractile organ in the whole body, and are more numerous close to that organ. This fact seems to have been overlooked by those gynaecologists who condemn the Alexander method for shortening the round ligaments and advise that the cords be sacrificed at the proximal end, preferring to retain the thick fibrous cord of the distal extremity to the thinner, but more muscular part near the uterus.

The uterosacral ligaments also contain muscular fibres, and are intimately connected with the fibres of the rectum which is, as we shall see, an important point in accounting for symptoms in retroversions. These ligaments possessed of muscular fibres are the most important, both in keeping the uterus in place and in restoring its balance after displacement. The uterus lies at an angle of about 45° with the plane of the vagina, supported by the loose areolar tissue that fills the space between the anterior walls of the vagina and the uterus itself, and is held forward by the round ligaments. About the junction of the body and cervix posteriorly are thrown out the fibres of the uterosacral ligament, whose duty is to hold the uterus backward and prevent it following the cervix into the vaginal canal. The other ligaments are folds of peritonæum and simply help to sustain the balance. The uterus receives the heft of the intestines on its rounded posterior surface, which casts them to either side, where they become a support rather than a load. So long as the proper relations are maintained, the uterus rests securely in its position and no such exercise as is consistent with the maintenance of good health will in any way affect it. All athletic exercises that tend to keep the body in good condition are a gain to the pelvic organs as they are to all other parts of the body, but the moment the equilibrium is destroyed many exercises that were useful before become decidedly pernicious.

The causes that bring about a lack of harmony with it, surely following retroversion, descent, and prolapse are many and varied. The habit so common among women of allowing the bladder to become overfilled is a frequent cause, and long sickness, such as typhoid fever, when the patient lies on the back for days and weeks, while every muscle is relaxed. Chronic inflammation of the cervix, especially following laceration, which inflammation often extends to the posterior ligaments, is another cause. This can be proved by the exquisite pain elicited when the

cervix is raised by the examining finger. Such a pain has long been looked on as a sign of endometritis, but it means more than that; it means that the posterior uterine ligaments are inflamed. Other causes are overexertion, producing great relaxation of all the muscles of the body; long continued tiring work; inflammation of the annexa; the torsal position after childbirth; subinvolution; resuming household duties after childbirth before the ligaments have recovered their tone; and the senseless use of the warm douche; also all growths so situated that they pull down or press down the uterus. Long walks, heavy lifting, straining, the wearing of tight clothing, and fastening heavy skirts around the waist, as well as many gymnastic exercises help toward retroversion. The round ligaments are stretched gradually and persistently, and while the fundus descends toward the sacrum the cervix rises toward the pubes, thus making traction on the posterior ligaments. It is during this period that the most prominent symptoms arise: eye symptoms, headache, indigestion, backache, and the whole train of reflex symptoms that follow strain on any organ of the body. We often hear a doctor say that the uterus is in very good position even when it stands midway between its normal position and the hollow of the sacrum. It is in a very good position to begin treatment, and if nothing is done for the patient this is only a start on the road to complete prolapse. In some cases when the uterus descends to the sacral hollow, nature interferes and adhesions are formed, preventing further descent. This is a condition that seldom produces symptoms, and leaves the woman about as well off as a ventrosuspension. *It is the progressive prolapse rather than the abnormal position that produces the painful symptoms.* It is during the progressive prolapse that constipation and rectal symptoms are prominent, for it is at that time that traction is made on the uterosacral ligaments, whose fibres are intimately connected with the rectum and which has the same nerve supply. We have seen too many cases where the pelvis was choked with a growth, and yet the action of the rectum was not interfered with, to suppose that a retroverted uterus always causes constipation. Where the uterus is movable, the case of the married woman during the childbearing period is of all the most hopeful, for if a pregnancy occurs the uterus must rise out of the hollow of the sacrum and at delivery with proper care it will assume the natural position.

There is no rule and there never will be any rule for treatment that will suit each individual

case, but we have two principles which we can observe: first, to relieve the symptoms, and, second, to follow nature as closely as we can in restoring the parts to their proper place. The highest form of gynecological work, and the only form that can offer a cure at the present time, is the non-operative.

I know that any treatment other than surgical is looked on with contempt, and that "routine treatment" and "tampon treatment" are terms of opprobrium in the profession. It is not the treatment, but the way in which it is carried out that is disgraceful. The term palliative has been applied to all such procedures, a term altogether misleading. No such treatment should be undertaken with any other goal in view than that of complete return to the normal, and the title of such treatment should be curative and not palliative.

Every case of retroversion not complicated by tumors, oophoritis, pustules, or the like, where the muscular tissue in the round and uterosacral ligaments is still capable of functioning, and where there is no mechanical obstruction, can be cured by replacing the uterus again, and again if necessary, applying properly a tampon, or, if there is no tenderness in the posterior ligaments a hard rubber pessary, massaging the uterus and annexa, building up the general health, wearing loose clothing suspended from the shoulders and taking the "knee chest position" from five to ten minutes twice daily, and practising walking on the hands and feet, or "elephant" walking, as it is called in the gymnasium.

Such a line of treatment judiciously carried out will cure any suitable case in the same length of time that is given to the removal of the symptoms by surgery, that is to say, two weeks in bed and two months of convalescence. Such a line of treatment should seldom be attempted at home unless the services of a nurse can be secured.

It is said, and with truth, that a woman has to be keyed up to the excitement of an operation before she will give herself the necessary time, but this is largely the fault of the physician. The patient is as clay in the hands of her medical adviser. And if he spoke with the same certainty of relief for her after medical as after surgical treatment she would submit even more willingly. As for the matter of expense, it is about equal.

What has brought everlasting disgrace and suspicion on this method is that it has been used again and again in unsuitable cases, and carried out in a slipshod haphazard way, by physicians who looked forward to no more definite termination than the end of the woman's patience. While

medical treatment is strongly to be recommended in suitable cases, it is just as strongly to be condemned in the unsuitable, that is to say, where there are complications that prevent the muscular ligaments from recovering their tone, where the muscle fibres have been destroyed by inflammation, where there are adhesions, oophoritis, salpingitis, and endometritis of a chronic form, such as that following gonorrhœal infection, or where a ruptured perineum or relaxed vaginal outlet makes it impossible for the uterus to maintain its equilibrium. In such cases there is actual loss of function from destruction of tissue and only palliative treatment can be thought of.

Sometimes the repair of a perineum or relaxed vaginal outlet with replacement of the uterus and keeping it in place with a pessary for a few months, is sufficient, or perhaps the clearing out of diseased glands and repair of the cervix are called for.

Curettage of the body of the uterus had better be deferred until some genius invents an instrument that will curette. I seldom use a curette, except in some cases of incomplete abortion, and then experience has taught me to rely largely on my finger. I have tried to curette a rubber bag, into which I had poured a non-soluble red jelly or paste. Splitting up the bag after a twenty minutes' conscientious attempt to clear it out with a curette and the use of several quarts of water, I was very glad that nobody's life depended on the completeness of that curettement. Another consideration that will often deter us from a curettage is that the corpus uteri is not at all so prone to inflammations as its more glandular cervix, and there is the risk of infecting a previously sterile body from an infected neck.

In the surgery of the pelvis, we must be governed by the conditions. Of the many complications there is not time to speak, though many of them are the direct cause of the displacement. As to the various ways of restoring the uterus by surgery, perhaps the shortening of the round ligaments offers the most promise with the least risk, but it should be kept in mind if the posterior ligaments are not functioning, that the uterus will be simply suspended from the round ligaments and will never give as much comfort to the patient as if the organ was raised up and anteverted, and held in that position by ventrosuspension, the main point in the choice between these operations being the condition of the posterior ligaments.

I have at present under my care a woman operated on fourteen years ago by a noted surgeon.

As a prevention to the descent of the uterus the operation was eminently successful, the fundus was well forward and the round ligaments could be palpated as tense and short, but the body and neck were in the same line and the uterosacral ligaments out of use. The patient told me that from the day she left the hospital to the present she was never free from pain, and I could well believe her. Nor is this a solitary instance. There is a large percentage of women operated on for this trouble who would not care to subscribe to the "cured" that stands after their names on the hospital books. But when their cases are studied carefully it will appear that they suffer, not because we have not the means at hand to relieve them, but because we do not apply the proper means to each individual case.

Ventrosuspension will always be the operation of election where there is annexal trouble that requires surgical interference, as the removal of tubes, ovaries, and the breaking of adhesions which are always found in connection with inflammations. Where the menopause is reached, we can rest assured that the symptoms will be removed and that we are not substituting one serious pathological condition for another. Ventrofixation with its variations remains as the only method in that class of cases in which the ligaments are crippled or deprived of their functional power by disease, while the Alexander method will yield many cases to medical treatment as our respect for medical methods increases.

Therapeutical Notes.

Removal of Nævi.—The child is put to sleep, writes Neiswanger in the *Alkaloidal Clinic*, for February, and a well wet pad, the size of the hand, is placed upon the abdomen and attached to the positive terminal of a galvanic battery. To the cathode is attached a short needle holder, in which is fastened a suitable needle—generally a long, slim one, from which the temper has been drawn. After the seat of operation has been cleansed and the needle drawn through an alcohol flame, it is passed *almost* through the mark, superficially, and parallel with the epidermis. The amount of current employed depends upon the distance the needle has been inserted, but usually is from $\frac{1}{2}$ ampere to 8 milliamperes, which is maintained until the usual blanched appearance indicative of decomposition is obtained. In like manner we attack every portion that is red, introducing the needle as many times as is necessary for the purpose.

The part is then dusted with boric acid, or other dry antiseptic, and in about a week a dark crust covers the whole area. This should not be disturbed until it is almost ready to drop off.

If the mark has not been very large, the resultant scar will be almost entirely absorbed in a few months, and even where the surface operated upon has been considerable, the scar will not be very noticeable in a year, because, it must be remembered, that the caustic action of the negative pole is very similar to that of any of the *alkaline* caustics, leaving a soft, pliable cicatrix that is easily absorbed.

Indigestion in the Adult.—In an article on Indigestion in *Treatment*, for December, 1904, Dr. Charles A. Beck says *inter alia*: In treating acute indigestion, dyspepsia, or gastric catarrh, in the *adult*, a speedy cure may be effected in the spontaneous removal of the ingesta from a stomach that has been treated like a gizzard. The best plan here is to encourage vomiting, one of the oldest and most simple of methods (that might be more frequently employed by the practitioner), by tickling the fauces with the finger (*care digitum!*), or by administering some tepid water. The patient is urged to take one glass after another (85°) until its nauseating effects on the palate and volume of gastric contents provoke free emesis. Another draught of water is then taken with the same effect, bringing away with it the remnants of the offending material and mucus. A third draught of water may now be given to which a little sodium bicarbonate (half a teaspoonful) has been added; this will neutralize the acid products of decomposition, and further dissolve and remove the mucus. A portion of the latter is left behind, and this, acting as a sedative to the gastric walls, will give speedy relief and rest. This method of treatment is simple, and may abort an acute attack of gastric catarrh; its application, however, will require discretion on the part of the practitioner. It must be remembered that old people stand vomiting and emetics badly; in some patients the above procedure might be dangerous, perhaps fatal, through rupture of a cerebral blood vessel. A rider might be added here: *All* medicines administered to old people, or to those having sclerotic arteries, should be made up as palatable as possible.

Hyperidrosis.—According to Unna, cited in *Nonceaux remèdes*, for February 8, 1905, washing the affected parts with spirits of camphor or a toilet vinegar of which eucalyptus is an ingredient, is valuable and may be followed by:

- R Ichthylol } of each.....5 parts;
Turpentine }
Ointment of zinc oxide.....10 parts.

M. For an ointment, to be used nightly.

In the shoes and socks may be sprinkled this powder:

- R Mustard1 part;
Powdered talcum.....30 parts.
M. Foot powder.

If the hands alone are affected, a half teaspoonful of the following may be thoroughly rubbed into the hands after each washing:

- R Eau de cologne.....90 grammes (3 ounces);
Tincture of belladonna.....15 grammes ($\frac{1}{2}$ ounce).
M. For the hands.

NEW YORK MEDICAL JOURNAL

AND

PHILADELPHIA MEDICAL JOURNAL.

A Weekly Review of Medicine.

ESTABLISHED IN 1865.

Entered at the Post Office at New York and admitted for transportation through the mail as second class matter.

NEW YORK, SATURDAY, FEBRUARY 25, 1905.

A RESERVE MEDICAL CORPS FOR THE ARMY.

At the last meeting of the Association of Military Surgeons of the United States Major Azel Ames, formerly a brigade surgeon of volunteers and previously to that an acting assistant surgeon in the army, presented an elaborate and, on the whole, a well considered plan for the organization of a medical reserve corps for the army, one intended to provide for the efficient supplementing of the regular medical service in times of emergency and at the same time to do away with the anomaly of the contract surgeon. Major Ames's paper is published in the February number of the association's *Journal*.

The reserve corps, according to the major's plan, should be a large one, and its members, enrolled under a sort of proportional system from all parts of the country, should have actual rank, but not be under pay except when they were called into active service. They should have the privilege of special instruction in the Army Medical School, and this might be advantageously supplemented or replaced, Major Ames thinks, by instruction on the correspondence plan. It appears that at the outset he thought he had good reason to expect that the surgeon general and the War Department would join in a movement to procure the Congressional action necessary to put the whole scheme into operation, but this expectation proved illusory, and in consequence the major was moved to some acer-

bity of expression concerning the regular medical corps. In the discussion that followed the reading of Major Ames's paper his reflections on the corps were shown, particularly by Major Jefferson R. Kean, to have been quite undeserved.

The legislation actually proposed cuts loose from the scheme of appointing the members of the reserve corps on geographical lines, and lodges the appointing power with the surgeon general. Since in time of war the corps will be drawn into active service and perform its functions under the surgeon general's responsibility, we do not see why the power of appointment should be vested elsewhere than in that officer. The legislation sought for also ignored the correspondence scheme of instruction. We are quite ready to admit that correspondence instruction is better than no instruction at all, but that, we fear, is the best that can be said of it. At least we should look upon it as quite inadequate to the military training of a body of medical officers appointed from civil life.

THE AMERICAN MEDICAL ASSOCIATION'S PROPOSED "DIRECTORY."

It is generally understood that the American Medical Association is about to publish a list of its members. There would be nothing extraordinary in the publication of such a list, but the fear seems to be widely entertained that a directory character is to be given to it, and that consequently those who are not members, and whose names accordingly will not be included, will be subjected to the risk of being said not to be in good standing. There are even some who think that this detrimental effect is foreseen and designed by the association as a means of coercing them into joining the organization. We feel sure that this must be a mistake, because any such action would be opposed to the spirit in which the association was formed and in which it has been supported for more than half a century, and because it would be suicidal as a matter of policy.

We should be sorry to think that the association was actuated by any such unworthy motive, but it is not easy to overlook the possibility of the result that is feared. The implication that a man is not in good standing unless his name appears in the "directory" is one that can readily

be cultivated to a vicious purpose, but it would be tremendously erroneous, and we believe that in every considerable community there would be no lack of practitioners brave enough to disregard it. We are all interested in promoting the real welfare of the American Medical Association, but many would resist coercion exercised in its name. The association was formed for the cultivation of medical science and for strengthening the bonds of brotherhood among physicians, and those who guided its early career had no thought of forcing their colleagues into its ranks. Surely it will not now be suffered to degenerate into a political machine, and those who represent the great mass of the members in the House of Delegates could readily be made to feel that this was the general sentiment, a sentiment behind which there would be the determination not to be coerced.

A REMARKABLE PRESCRIPTION.

Dr. Henry Beates, Jr., of Philadelphia, contributes to the February number of the *American Journal of Pharmacy* an article which he introduces with the following prescription:

R Aconitiae Cryst, Merck.....Gr. 1-20;
Resinæ Phosphori, 4 per cent.....Gr. v;
Calci Phosphatis.....Gr. xlviii;
Misce et fiant capsulas numeros quatuor et viginti.
SIGNA.—One every two hours for four or five doses, then one every four hours, constitutes an "instrument" which is exponent of many facts associated with life and the profoundest interests of human existence.

"The prescription," Dr. Beates adds, without specifying whether he means this particular one or a prescription in general, "is designated 'an instrument' because of its legal significance, for it is a 'writing acknowledging or certifying to a claim, or recording the terms of a contract, deed, or grant,' and by common consent presupposes a right, by reason of the possession of qualification, to formulate and to have compounded and administered, without harm, according to obtaining conditions." We understand Dr. Beates as meaning that a prescription in general is "an instrument" such as he describes, that a properly qualified person has a right to write it and have it put up and administered, and that such administration will be "without harm according to obtaining conditions." We judge that he thought it unnecessary to comment specifically on the pre-

scription quoted, but simply cited it as a horrible example of what a prescription ought not to be, whether from his own point of view of it as an "instrument" or from any other.

We cannot make out that the prescription cited acknowledges or certifies to a claim or records the terms of a contract, deed, or grant. It has the negative disqualification, therefore, of not answering to Dr. Beates's definition of "an instrument." It has certain other peculiarities—for example, that of a Latinity unique in the phrase "fiant capsulas numeros," and that of incorporating in the directions to be written on the label a general statement having, we should say, "nothing to do with the case." Dr. Beates saw, of course, that all this would strike his readers at once, and he accordingly withheld specific comment. Dr. Beates's article is one of a number written to prove the necessity of higher education on the part of both physicians and pharmacists, all of which are printed in the same number of the *American Journal of Pharmacy*, and a perusal of them will doubtless accomplish much toward convincing the readers of that journal that such higher education is devoutly to be wished for.

THE ASEPTIC OBLIGATIONS OF MIDWIFERY.

From the present standpoint of the bacteriologist, it can be stated, without argument here, that the healthy vagina is immune to pathogenic organisms. That its acid secretions are germicidal is demonstrated by the experiments of Krönig, Duerksen, and others, who after placing various organisms in the vaginas of healthy women found that the canal was sterile after forty-eight hours. Streptococci die first, then, in the order named, staphylococci and pyocyanæi, the two last living twice as long as the first. Gonococci, on the contrary, find the same acid secretions a favorable medium for development, and are hence active, not only in the vagina, but also within the uterus and tubes.

Quite a different condition exists about the vaginal entrance. Here micrococcic life is luxuriant, as might be expected from the environment of these parts; their nearness to the anus, their opportunities for contamination with decom-

posed urine, cutaneous excretions, and soiled clothing, and for infection by personal handling. The integument of the pudendum, being partly true skin and partly transitional between skin and mucous tissue, provides a natural habitat for such microorganisms. Even in the healthy woman, then, the outlet of the birth canal is naturally and artificially septic, and that this condition is universal is proved beyond question.

The obstetrician must accept the facts, therefore, that the birth canal, considered in its entirety and as he finds it, is neither wholly clean nor wholly infected, and that the degree of infection varies according to the distance of the point in question from the outlet, steadily lessening, however, from below upward. Edgar found that the secretions in the vulvar canal of twenty-eight pregnant and parturient women showed pyogenic organisms in forty per cent. of the cases, though in all but two of the women the external genitals had been washed with soap and water just previous to making the cultures. In the healthy parturient, then, the septic enemy is openly massed at the entrance of the birth canal, while its scouts are ambushed in reduced force within the passage. The objective points, therefore, for attacking the enemy—in providing for and maintaining asepsis in labor and the puerperium—are the introitus, the vulva, and the adjacent regions.

The deduction from these statements is obvious; when the healthy vagina is normally immune, infection, if received at all, must be from without. Though autoinfection may and undoubtedly does exist, it is relatively so infrequent that, for the present purpose, that factor in puerperal septicæmia may be disregarded. In the main, labor is a natural process, carried on under natural laws and safeguards. During the function the birth canal is specifically immunized by the vaginal bacilli, naturally antagonistic to cocci, by leucocytosis, by the absence of free oxygen as a culture medium, and by the outward flow of the vaginal secretions; and is mechanically sterilized by the flushing of the passage with liquor amnii and blood and by friction against its walls of the child and placenta during their expulsion. From all this it follows inevitably that any interference with the spon-

taneous process, particularly by intrusion into the birth canal through an infected entrance, deranges its orderly course and weakens its natural defenses.

The obstetrician's unmistakable relation to his patient is that of an ally rather than an enemy; he exists solely to help parturition. His first important service at the bedside is to find out whether labor is to be natural or whether his aid will be requisite. In deciding the question he makes use of the principles of his art to establish the relation of the passenger to the passage, that is, he examines for position. Up to within very recent times the only accepted method of the examination was by palpation of the presenting part by way of the vagina. Now he ascertains the fetal position by abdominal palpation and auscultation, reserving internal examination for confirmation of his previous abdominal study and for such minor purposes as observing the character and progress of cervical dilatation, the condition of the passage as respects its adaptation to the passenger, etc. But just here the great superiority of the method of external examination over the vaginal becomes evident; it precludes all risk of infection. Experiments show that the danger of systemic infection increases *pari passu* with the number of internal examinations, being least when these are omitted entirely and greatest when they are frequent. That the foetal position can be determined in the majority of cases better by the external method than by the internal, is a fact of daily experience; that it is safer needs no argument. The only inference from these statements—and to deny them is to confess one's ignorance of modern obstetrics—is that those practitioners who still use internal examinations, to the exclusion of external, for diagnosing position, subject the woman to the hazard of sepsis. They either ignorantly or deliberately commit an assault upon the rights of the patient.

Granting that it is practically impossible to sterilize the vaginal outlet, yet much may be done toward that result. It is manifestly impracticable to try to cleanse its delicate surfaces with the same elaborateness which one would use for the coarser, less sensitive skin of the abdomen. Energetic scrubbing of the pudendum with brush,

soap, hot water, and chemicals would not be tolerated by the patient unless anesthetized, and, whether she was conscious or unconscious, such work would almost surely lacerate its tissues, thereby offering ready entrances to the ubiquitous germs. The clinical results of many conscientious practitioners bear witness to the value of simple soap and water as a prophylactic against infection. I believe that if, at the beginning of the first stage, the usual surface microorganisms were carefully removed from the introitus by this means alone, the natural germicidal provisions for labor would maintain sufficient immunity against those residual germs in its deeper layers, which cannot be removed artificially. Should operative assistance become needed, the first cleansing, repeated under anesthesia, may approach more nearly to the ideal. Once clean means continuously clean; the more protracted the labor the more frequent the disinfecting.

Thus much of sterilization is possible for every lying-in woman, in private or public, without offending her modesty or inflicting pain. Whether in addition every one must have the vulvar and pubic hair shaved is disputable; it is a question of time, availability of the trained nurse, the after-discomfort during renewal of the growth, etc. When the hair is luxuriant, it ought certainly to be clipped with scissors, and I have never found a patient who objected to this practice after its purpose had been explained to her. The ante partum douche, plain or medicated, in the healthy woman is not only unnecessary, but on the contrary is improper because it removes the natural protective. The golden mean in antiseptics, between the extreme technics of the abdominal surgeon and its burlesque by "our friends, the enemy," lies in not attempting too much, but in making a little go a great way. The danger of carrying sepsis through an infected entrance, while trying to locate the fetus by vaginal palpation, more than balances any good that the patient will gain by that method of diagnosis. The cardinal point in the details of the bedside toilet, so far as it concerns the patient, lies certainly in the initial cleansing of the external genitals.

Of the various plans devised for sterilization of the hands, that one most appeals to the ob-

stetrician which combines in itself simplicity, effectiveness, and cheapness. The method lately recommended by Harrington, while probably most germicidal of all, requires the free use of alcohol, after the usual scrubbing with soap and water and a five minutes' immersion under a seventy-five per cent. alcoholic solution of mercury bichloride. It is manifestly impossible to add to the various necessary articles carried in the obstetrical satchel a quart bottle or two of alcohol. Allowing that this mode of sterilizing is best for the amphitheatre, for the ordinary bedroom the handiest germicide is still the time honored bichloride tablet, "cheap and fillin' for the price," and it must be a very poverty stricken house which cannot provide a piece of laundry soap. The coal tar derivatives are preferred by many to the mercurial, and a sufficient quantity of either takes up but little room in the satchel. Rubber gloves are steadily gaining a place in the lying-in room, particularly for all operative and intrauterine work, but their two essential defects, expense and fragility, hinder their general adoption. Many good obstetricians restrict their antiseptic toilet to the use of soap and water, limiting their vaginal examinations to the least number possible. Supposing that this alone is competent manual disinfection, it must be granted by those who rely upon it that only superficial microorganisms can be removed by a single washing, however thorough. For since the deeper layers of bacteria are constantly working their way upward, as the external epithelia become softened by contact with fluids and wiped off by friction, true immunity can be maintained only by frequent repetition of the preliminary washing. The final word upon the subject of sterilization of living tissues is not yet said, and the best method for its attainment awaits its discoverer. But the proved benefit to the parturient of antiseptics, even if the best method of its application is yet unsettled, makes the principle doubly insistent, and that there are many defects in its working details is no excuse for discarding the principle entirely. The rule for the obstetrician must be absolute; no unclean hands in the vagina.

During the last hundred years of midwifery two results stand contrasted; throughout three

quarters of the century puerperal septicæmia was much more prevalent in institutional than in family practice, in the last quarter these facts are exactly reversed. Infective processes during the puerperium are the rare exception in the public maternities of to-day, a statement proved by the records of such institutions the world over. The relative percentage nowadays in the home cannot be computed so accurately as that in the maternities, because of evident difficulty in gathering the requisite data. The most reliable source of information upon this point is probably the annual reports of the various State health departments, but these are misleading because they tell the truth, but not the whole truth. For illustration, in case of death due to any of the diseases classified as belonging to "the puerperal state," the local death certificate not infrequently states it as due to one or more of the secondary conditions arising during the course of the primary disease; to pneumonia, or exhaustion, or malaria, etc., rather than to puerperal septicæmia or puerperal metritis or childbed fever. The bearing of this well known fact, so far as it relates to the accuracy of mortuary statistics of private midwifery, is obvious. It is estimated by those best competent to decide that the mortality and morbidity of childbed in the home are fully as large, if not larger, than a generation ago. The readiest explanation for this lamentable and inexcusable condition must be that the family physician and midwife deliver their patients with the same indifference to sepsis which their fathers had. In the public maternity everything that touches the birth canal must be sterile; in private midwifery sterility depends upon the choice of the attendant, thereby making life for the mothers of our children measurably safer in the ward of the hospital than in the privacy of the home. Apparently the only incentive which will induce the majority of general practitioners to change their present irrational routine of delivery for that of the protective method is the compulsion of an educated public sentiment. "The Lord rewarded me according to His righteousness; according to the cleanness of my hands hath He rewarded me."

—*Psalms* xviii, 20.

STANLEY P. WARREN.

THE PROPOSED "BLANKET" CERTIFICATION OF CLINICAL THERMOMETERS.

In our issue for January 21st we asked our readers to give us their opinion as to what fraction of a Fahrenheit degree might be regarded as negligible in the deviation of a clinical thermometer from absolute accuracy—an extent of deviation, that is to say, that might be held to be so small as practically to justify the certification of the instrument as correct. We have been gratified at the number of communications on the subject that we have received, many of which have come from men of the greatest eminence in the profession and of vast clinical experience. But we do not think it well to base any general statement on these data, preferring to wait for still more numerous responses. We mention the matter now for the purpose of impressing upon all our readers the importance of a full expression of opinion on the very practical point involved, for it will doubtless have great influence in enabling the government Bureau of Standards to come to a conclusion. When time enough has elapsed to warrant us in thinking that we have received all the data to be expected, we shall recur to the subject.

A PHENOMENAL PIECE OF EFFRONTERY.

It is reported that a certain individual expects to recover from a New Haven surgeon the sum of \$25,000 damages for sufferings and disabilities alleged to have resulted from the leaving of a pledget of gauze in his abdomen at the time of an operation for appendicular disease. A jury capable of bringing in such an award might appropriately resolve itself into an association for honoring the memory of Rogue Riderhood, who, it will be remembered, having been rescued from drowning by a tug, swore he would sue the owners of the craft for the loss of his hat.

THE AMERICAN ANTITUBERCULOSIS LEAGUE.

The meeting of this organization which is to be held in Atlanta on April 17th, 18th, and 19th, under the presidency of Dr. George Brown, will undoubtedly prove to be one of great importance. Many State and other medical societies will be represented, and the Georgia State Commission on Tuberculosis and the Georgia Antituberculosis League will meet in Atlanta at the same time.

RECENT PUBLICATIONS BY THE ILLINOIS STATE BOARD OF HEALTH.

This enterprising and alert board has recently issued a valuable pamphlet entitled *Smallpox: its Prevention, Restriction, and Suppression*, and has published also a fourth edition of its brochure on *The Cause and Prevention of Consumption*. The circulation of such literature cannot fail to be productive of a great amount of good.

News Items.

Society Meetings for the Coming Week:

MONDAY, February 27th.—Medical Society of the County of New York; Lawrence, Mass., Medical Club (private); Cambridge, Mass., Society for Medical Improvement; Baltimore Medical Association.

TUESDAY, February 28th.—New York Medical Union (private); Metropolitan Medical Society, New York (private); Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Richmond, Va., Academy of Medicine and Surgery; Rome, N. Y., Medical Society; Boston Society of Medical Sciences (private).

WEDNESDAY, March 1st.—New York Genitourinary Society; New York Academy of Medicine (Section in Public Health); Society of Alumni of Bellevue Hospital, New York; Harlem Medical Association of the City of New York; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond, N. Y. (New Brighton); Penobscot, Me., County Medical Society (Bangor); Bridgeport, Conn., Medical Association.

THURSDAY, March 2nd.—New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, N. Y.; Boston Medico-psychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, March 3rd.—Manhattan Clinical Society; Practitioners' Society of New York (private); Clinical Society of the New York Postgraduate Medical School and Hospital; Baltimore Clinical Society.

SATURDAY, March 4th.—Manhattan Medical and Surgical Society, New York (private); Miller's River, Mass., Medical Society.

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending February 18, 1905:

	February 18.		February 11.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	209	8	201	3
Diphtheria and croup	272	47	275	42
Scarlet fever	225	20	246	14
Smallpox	1	1	3	1
Chickenpox	132	1	101	1
Tuberculosis	339	171	368	181
Typhoid fever	23	4	28	4
Cerebrospinal meningitis	40	4	29	4
	1,201	291	1,222	274

The Society of Medical Jurisprudence.—At the regular meeting of this society, held on February 20th, Professor Wilhelm Waldeyer, of Berlin, was elected an honorary member.

Mount Sinai Hospital.—Dr. Emil Mayer, adjunct attending laryngologist to the Mount Sinai Hospital, has been appointed chief of clinic to the ear, nose, and throat department of the dispensary of that institution.

Fango Institute of New York.—An institution for the application in selected cases of genuine Italian fango has been opened at 69 West Ninetieth Street. The institution also offers facilities for all kinds of baths and is under superior medical supervision.

Orthopædic Hospital.—The two concerts for the benefit of the Orthopædic Hospital, at which M. Ysaye and Herr Kreisler will appear in the Bach concerto for two solo violins, and which will take place on Monday evening, March 13th,

and Tuesday afternoon, March 14th, promise to be unusually successful. The New York Symphony Orchestra, under the direction of Walter Damrosch, also will play. The boxes, seating six, are \$30 each, and prices for seats range from \$2.50 down to \$1.

At the Medical Society of the County of Kings a lecture was given last Tuesday on Observations in Japan and Manchuria with Both Armies and Their Bearing on the Reorganization of the Medical Department of the United States Army, by Major Louis Livingston Seaman, late surgeon in the United States Volunteer Engineers, with the allied forces in China during the late Boxer uprising; with the United States Army in Cuba during the Spanish-American War, etc., etc.

Baby Hospital in Need.—The directors of the hospital for babies at Lexington Avenue and Fifty-fifth Street have issued an appeal to the public for aid. Opened in 1902, its full capacity was required within six months, and it now finds itself face to face with the problem of how the increased demands on its service can be met. Last summer one third of the patients applying for admission had to be rejected. The endowment fund should not be encroached upon, but its integrity is menaced. The immediate need has been met by the acquisition of a house adjoining the hospital. The necessary changes have, however, necessitated the raising of \$25,000. Contributions may be sent to the treasurer, Henry R. Kunhardt, 17 Battery Place, New York.

The Manhattan Maternity Hospital and Dispensary, at 327 East Sixtieth Street, was opened on February 16th. The building is square, of five stories and basement, and built of brick with a white enamel finish. On the main floor are the dispensary, the examining and admitting rooms, an office and superintendent's reception room, with the students' dormitory and dining room. On the floor above are the wards, accommodating eighteen patients, and the nurseries for both the ward and private patient babies. There are single cribs in the latter, and in the former little three-baby cribs with a couple of single ones for isolating the children when that is necessary. The ward patients' dining room is also on this floor. All the rooms are bright and light, there being windows on all sides of the building. On the third floor are the private rooms. On the fourth floor at one side is the operating room and amphitheatre, with seats extending up into the top story. On the top floor are the superintendent's suite of room and a private dining room, nurses' dining room, the house kitchen, and big supply room.

PHILADELPHIA.

West Philadelphia Medical Association.—The initial meeting of this association was held on February 10th at Rittenhouse Hall, Fifty-third Street and Haverford Avenue. The following officers were elected for the ensuing year: President, Dr. A. F. Targette; vice-president, Dr. George C. Shammo; recording secretary, Dr. William B. Bacon; financial secretary, Dr. A. P.

Good; treasurer, Dr. J. Brittingham. The association has a membership of seventy-five physicians.

Scientific Society Meetings for the Week Ending March 4, 1905.—Monday, February 27th, Mineralogical and Geological Section, Academy of Natural Sciences. Tuesday, February 28th, Northwest Medical Society; Philadelphia Neurological Society. Wednesday, March 1st, College of Physicians; Association of Clinical Assistants of Wills's Hospital. Thursday, March 2nd, Obstetrical Society; Medical Society of the Southern Dispensary. Friday, March 3rd, American Philosophical Society.

Special Lectures at the University of Pennsylvania.—The faculty of the University of Pennsylvania has arranged the following lectures upon subjects which are of more or less general interest. While designed especially for the instruction of the fourth year class, invitations have been extended to the physicians of Philadelphia to attend on Monday at four o'clock in the new medical laboratories: February 6th and 13th, Dr. Leonard Pearson, Milk Supplies of Cities; February 20th, Dr. J. F. Schamberg, Vaccination; February 27th, Dr. J. F. Schamberg, Demonstration Upon the Subject of Eruptive Fevers; March 6th and 13th, Dr. E. C. Kirk, The Medical Relationship of Certain Dental and Oral Disorders; March 20th, Dr. A. P. Francine, The Restriction and Prevention of Pulmonary Tuberculosis; March 27th, Dr. R. Tait McKenzie, The Therapeutics of Exercise; April 3rd and 10th, Dr. Joseph Sailer, Hydrotherapy.

The Health of the City.—During the week ending February 11, 1905, the following cases of transmissible diseases were reported to the Bureau of Health:

	Cases.	Deaths.
Typhoid fever.....	95	8
Scarlet fever.....	41	1
Chickenpox.....	79	0
Diphtheria.....	63	14
Cerebrospinal meningitis.....	1	0
Measles.....	6	1
Whooping cough.....	15	2
Tuberculosis of the lungs.....	43	67
Pneumonia.....	113	117
Erysipelas.....	7	3

The total deaths for the week were 612, in an estimated population of 1,438,318, corresponding to an annual death rate of 22.13 per 1,000 population. The total infant mortality is 122; under one year, 91; from one to two years, 31. There were 41 still births; 22 males and 19 females. The following deaths were reported from other transmissible diseases: tuberculosis, other than tuberculosis of the lungs, 5; puerperal fever, 3; diarrhoea and enteritis under two years, 11. The temperatures reported by the weather bureau have been unusually low, ranging from a maximum of 38° on the 10th to a minimum of 9° on the 5th.

Charitable Bequests.—Leo Loeb and William B. Hackenberg, executors of the estate of Selina Walker, will distribute the following sums to various Hebrew charities in accordance with the adjudication of the estate by Judge Hanna, of the Orphans' Court: Jewish Foster Home and Orphan Asylum, \$9,965.64; Jewish Hospital Association, \$7,286.73; United Hebrew Charities,

\$7,286.73; Hebrew Education Society, \$2,428.90; Alliance-Israelite (Philadelphia Branch), \$2,428.90; Orphans' Guardians' Society, \$2,428.90; Jewish Maternity Hospital, \$2,428.90.

In adjudicating the estate of Countess Ellen de Cuelebroeck, who died in 1903, Judge Hanna, of the Orphans' Court, awarded a balance of \$20,488.95 to various charities.

By the will of Francis T. Fassett the Children's Hospital receives \$5,000 for the purpose of endowing a free bed, to be known as the "Anne Avour Fassett Bed," in memory of the wife and daughter of the testator.

By the will of A. Heineman \$500 each is devised to the Jewish Foster Home, the Jewish Orphan Asylum, and the United Hebrew Charities. Three hundred and fifty dollars is bequeathed to the Jewish Maternity Home.

Jewish Hospital Staff.—The work of the Jewish Hospital was so much increased during 1904 that it was found necessary to enlarge the staff. The president of the institution, William B. Hackenberg, announced the following staff on February 3rd:

Consulting surgeons—Dr. William W. Keen, Dr. J. William White, Dr. John B. Roberts, Dr. Edward E. Montgomery, Dr. Orville Horwitz, Dr. John M. Baldy, Dr. Charles P. Noble. Surgeons—Dr. Benjamin B. Wilson, Dr. Lewis W. Steinbach, Dr. William H. Teller, Dr. William L. Rodman, Dr. Max J. Stern, Dr. Melvin M. Franklin. Orthopaedic surgeon—Dr. DeForest Willard. Ophthalmologists—Dr. Isaac Leopold, Dr. Jay C. Knipe. Neurologists—Dr. Francis X. Dercum, Dr. Max H. Bochroch. Otologists—Dr. S. MacCuen Smith, Dr. Eli L. Klopp. Laryngologists—Dr. Arthur W. Watson, Dr. Louis Jurist. Obstetrician—Dr. William H. Randle. Pediatricists—Dr. Thompson S. Wescott, Dr. Ludwig Loeb, Dr. Joseph B. Potsdamer. Pathologist—Dr. Courtland Y. White. Dermatologist—Dr. Jay F. Schamberg. Radiologist—Dr. Sydney L. Feldstein. Consulting physicians—Dr. John H. Musser, Dr. James Tyson, Dr. James C. Wilson, Dr. Roland G. Curtin, Dr. Alfred Stengel, Dr. James M. Anders, Dr. Lawrence F. Flick. Consulting pediatricist—Dr. J. P. Crozer Griffith. Physicians—Dr. Adolph Feldstein, Dr. Thomas Betts, Dr. Solomon Solis-Cohen, Dr. William A. Cross, Dr. Francis X. Dercum, Dr. David Riesman, Dr. Courtland Y. White. Assistant physicians—Dr. Moses H. Behrend, Dr. Bernard Kohn, Dr. William A. Rocap, Dr. Edwin I. Becker, Dr. Victor A. Loeb, Dr. Maurice J. Karpeles, Dr. Harry F. Webster, Dr. Myer Solis-Cohen, Dr. George P. Katzenstein, Dr. Louis H. Jacobs, Dr. Milton K. Myers, Dr. William Shields, Dr. George W. Cook, Dr. Samuel Leopold, Dr. Mortimer Herzberg, Dr. Robert F. Ridpath. Chief resident physician—Dr. Edwin A. Jarecki.

Course of Instruction in Public Health.—The authorities of the University of Pennsylvania realize the efforts which are being made in communities throughout the country to obtain officials who have had some special training in matters pertaining to public health. Each year the demands for men of this type (either as chiefs of departments or in some subordinate position) is increased, and at the present time there is a lack of men qualified to fill such positions. To meet the needs of such demand, the university will introduce into its curriculum, beginning October 1, 1905, the following course in public health:

Sanitary Engineering.—Including the subject of water supplies, sewerage systems, street cleaning, disposal of waste, etc. **Sanitary Legislation.**—A study of the movement for sanitary reform, and of the laws enacted relating to public health, and the methods of enforcement employed in Great Britain and the United States. **Inspection of Meat,**

Milk, and Other Animal Products.—The methods of preparation and preservation of the same, the conduct of dairies, creameries, etc., and demonstrations of the diseases of animals transmissible to man. *The Sanitary Engineering of Buildings.*—Including demonstrations of systems of heating, ventilation, plumbing and drainage, the study of plans, etc. *Social and Vital Statistics in the United States.*—An examination of statistical methods and their results, with special reference to vital statistics and to city populations. *Practical Methods Used in Sanitary Work.*—Including water, air, and milk analyses, studies in ventilation and heating, investigation of the soil, methods of disinfection, sterilization, etc. (This is purely laboratory instruction.) *General Hygiene.*—As applied to the community, including lectures upon the causation of disease—exciting and predisposing, methods of prevention—including isolation, quarantine, natural and acquired immunity, protective inoculation, vaccination, and the antitoxic state, methods of house disinfection and the means employed, suggestions for the organization of sanitary work, the influence of water supplies and sewage disposal on the public health, etc. *Personal Hygiene.*—Including the physiology of exercise, the adaptation of exercise to the various physical requirements, the use of exercise for the prevention and correction of deformities, the methods of examination and record keeping, the routine physical examination of growing children and the relation of air, food, bathing, etc., to health and development; the hygiene of the school room.

GENERAL.

The Case of Dr. Harper, President of Chicago University.—In response to our telegraphed inquiry regarding the case of Dr. Harper, President of Chicago University, we have received the following wire: "The suspicions of malignant disease of the cæcum are well founded and have unfortunately been corroborated by Dr. McBurney's exploratory incision."—NICHOLAS SENN."

Minneapolis Assistant City Physician.—Dr. O. E. Linjer, who has held this position for some time, has resigned to devote himself entirely to his private practice.

Richmond, Va., Academy of Medicine and Surgery.—The subject announced for discussion by this organization at its next meeting on February 28th is Movable Kidney, by Dr. H. S. McLean and Dr. Blanton L. Hillsman.

Connecticut State Board of Health.—The following cases of infectious diseases have been reported to this board for January, 1905: Measles, 228; scarlet fever, 184; diphtheria and croup, 208; cerebrospinal fever, 2; whooping cough, 55; typhoid fever, 29; consumption, 46.

The Fulton, N. Y., Physicians' and Surgeons' Association has elected the following officers for the current year: President, H. P. Marsh, M. D.; vice-president, L. F. Joy, M. D.; secretary and treasurer, A. L. Hall, M. D.; censors, Dr. Fox, Dr. Haviland, and Dr. Scott.

The Obstetrical Society of Cincinnati has installed new officers as follows: President, Dr. R. W. Stewart; vice-president, Dr. Ambrose Johnson; recording secretary, Dr. John H. Landis; corresponding secretary, Dr. E. S. McKee; treasurer, Dr. L. S. Colter.

The First District Branch Medical Society of Kansas held its annual meeting on February 9th in Kansas City, Kans. Afternoon and evening sessions were held at the council chamber in the

city hall. Officers were elected for the coming year as follows: President, Dr. P. D. Hughes, of Kansas City; vice-president, Dr. H. L. Alkire, of Topeka; secretary, Dr. James Naismith, of Lawrence; treasurer, Dr. C. C. Goddard, of Leavenworth.

Bequest to Trenton, N. J., Hospitals.—Miss Margaret W. Tantum and her aunt, Mrs. Myra V. Freas, have notified the managers of the three public hospitals in Trenton that each institution is to be given an amount aggregating \$35,000 for the establishment of free beds in memory of the late Dr. James D. Tantum. Dr. Tantum was one of the wealthiest citizens of Trenton. He died recently from the effects of an operation in a Philadelphia hospital. He left no will, but on his deathbed requested his daughter and sister to give from his estate \$35,000 to three hospitals in Trenton and \$5,000 to the German Hospital in Philadelphia.

Pure Food Investigation in the New York Legislature.—A resolution was introduced in the assembly by Mr. Sheldon on February 14th. It is apparently aimed at the investigation of the present situation with reference to adulteration of foods and medicines, and calls on the State health department for a report on the subject with recommendations for remedies. The resolution is as follows:

Resolved, That the commissioner of health be and hereby is requested to furnish to this house a statement of what effort has been made on the part of the department of health for the enforcement of said statute, and whether, in his opinion, other or increased facilities or enactments are essential for the proper enforcement of the pure food law within this State.

Examinations for Admission to the Army Medical Corps.—Preliminary examinations for appointment of assistant surgeons in the army will be held on May 1 and August 1, 1905. Permission to appear for examination can be obtained upon application to the Surgeon General, United States army, Washington, D. C., from whom full information concerning the examination can be procured. The essential requirements to securing an invitation are that the applicant shall be a citizen of the United States, shall be between twenty-two and thirty years of age, a graduate of a medical school legally authorized to confer the degree of doctor of medicine, shall be of good moral character and habits, and shall have had at least one year's hospital training or its equivalent in practice. The examinations will be held concurrently throughout the country at points where boards can be convened. Due consideration will be given to the localities from which applications are received, in order to lessen the traveling expenses of applicants as much as possible. In order to perfect all necessary arrangements for the examinations of May 1st, applications must be complete and in possession of the Surgeon General on or before April 1st, and for the examination of August 1st, on or before July 1st. Early attention is therefore enjoined upon all intended applicants. There are at present twenty vacancies in the medical corps of the army.

The Röntgen Congress in Berlin.—April 30 to May 3, 1905. The Berlin Röntgen Society (*Röntgen Vereinigung zu Berlin E. V.*) has arranged for a congress in commemoration of the first decennial of Röntgen's discovery, to be held under the auspices of Dr. von Bergmann, honorary president, and of an honorary committee headed by the Prussian Minister of Instruction and His Majesty's physician, the Surgeon General of the Prussian Army, and including the president of the *Troisième congrès d'électrologie et de radiologie* for those in Germany and other countries interested in the investigation, technics, and employment of the Röntgen ray.

The congress, together with an exhibition of apparatus, radiograms, etc., will be held in the rooms of the *Ressource* in the Latin quarter of Berlin (N. 24, Oranienburgerstrasse 18) on the four days succeeding Easter week.

The executive committee of the congress and exhibition is composed of Professor Eberlein, chairman; Dr. Immelmann, Berlin W., Lützowstrasse 72, secretary; and Dr. Cowl, treasurer, who will continue to receive and acknowledge applications for membership, contributions to the proceedings, and other communications concerning the congress and exhibition.

Cards of membership will be issued after April 26th at the bureau of the congress. The cost, including a copy of the volume of proceedings, is 15 marks, 15 shillings, or \$3.60, which should be sent in advance to the treasurer.

Early notice of participation, with exact address, title of paper, etc., is desirable. It may be found necessary to restrict the time devoted to a single communication, discussion, or demonstration.

An explanatory circular concerning the exhibition, which is to be devoted to new and interesting articles pertaining to the Röntgen ray will be gladly sent on early application.

If those who address the congress in English will previously send in a short digest of their remarks, the same will be rendered in German at the conclusion of their papers.

The American Therapeutic Society.—The sixth annual meeting will be held in Philadelphia, Pa., May 4, 5, and 6, 1905. Following is the programme:

The Value of Ergot as a Sedative, by Dr. Torald Sollmann, of Cleveland, O.; The Proper Sphere of Bromides in Epilepsy, by Dr. Frederick Peterson, of New York city; The Radiation Treatment of Tuberculous Glands, by Dr. William J. Morton, of New York city; The Prevention and Treatment of Uremia in Acute Nephritis, by Dr. Howard Van Rensselaer, of Albany; The Management of Chronic Parenchymatous and Chronic Interstitial Nephritis, by Dr. Solomon Solis-Cohen, of Philadelphia, Pa.; The Remedial Value of Hypnotic Cumulative Action, by Dr. George F. Butler, of Chicago, Ill.; The Value of Physiological Salt Solution in Circulatory Failure, by Dr. H. C. Wood, Jr., of Philadelphia, Pa.; The Action of Certain Drugs in Heart Disease, by Dr. Thomas E. Satterthwaite, of New York city; The Exhibition of Several Cases of Skin Disease, by Dr. John V. Shoemaker, of Philadelphia, Pa.; The Recognition and Treatment of Cholecystitis, by Dr. Robert T. Morris, of New York city; The Etiology and Treatment of Recurrent Duodenal Congestion and Inflammation, by Dr. Howard H. Barker, of Washington, D. C.; The Diet in Non-Inflammatory Intestinal Indigestion, by Dr. George B. Fowler, of New York city; The Treatment of Chronic Diarrhea, by Dr. Reynold W. Wilcox, of New York city; Rectal Alimentation, by Dr. William H. Porter, of New York city; The Etiology and Treatment of Infantile Atrophy, by Dr. John B. White, of New York city; Notes on the Treatment of Hay Fever and Asthma, by Dr. Charles H. Knight, of New York city; Drug Adulterations, by Dr. Harvey W. Wiley, of Washington, D. C.; The Prophylaxis of Pneumonia, by Dr. James M. Anders, of Philadelphia, Pa.; The Recognition and Treatment of Pancreatic Inflammations, by Dr. Carl Beck, of New York city; The Management of Injuries to the Knee Joint, by Dr. De Forest Willard, of Philadelphia, Pa.; The Treatment of

Neuritis, by Dr. Daniel R. Brower, of Chicago, Ill.; The Value of the Correction of Errors of Refraction in Psychoses, by Dr. Edward D. Fisher, of New York city; The Management of Dysmenorrhœa, by Dr. Egbert H. Grandin, of New York city; The Treatment of Incontinence of Urine in Children, by Dr. Noble P. Barnes, of Washington, D. C. Chairman of committee on arrangements, Dr. John V. Shoemaker, 1519 Walnut Street, Philadelphia.

Statement of Mortality in Chicago for the Week Ending February 18, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on estimated midyear populations of 1,990,750 for 1905 and of 1,932,315 for 1904:

	Feb. 18, 1905.	Feb. 11, 1905.	Feb. 20, 1904.
Total deaths, all causes.....	630	554	651
Annual death rate per 1,000.....	16.50	14.50	17.61
Males.....	351	319	375
Females.....	279	235	276
By ages—			
Under 1 year.....	149	123	128
Between 1 and 5 years.....	64	82	50
Over 60 years.....	116	103	145
Principal causes of death—			
Acute intestinal diseases.....	25	20	29
Apoplexy.....	15	19	18
Bright's disease.....	36	32	41
Diphtheria.....	35	40	35
Consumption.....	73	67	70
Cancer.....	21	21	21
Convulsions.....	20	14	20
Diphtheria.....	6	11	12
Heart diseases.....	45	37	50
Influenza.....	8	12	5
Measles.....	1	8	0
Nervous diseases.....	27	21	20
Pneumonia.....	136	118	170
Scarlet fever.....	3	3	9
Smallpox.....	4	2	0
Suicide.....	10	8	7
Typhoid fever.....	2	4	8
Violence (other than suicide).....	24	22	20
Whooping cough.....	3	10	0
All other causes.....	136	84	116

A total of 426 deaths was recorded by the bureau of vital statistics during the first four days of the week—a total which represents an annual death rate of 30.2 per thousand of population. This is a figure not reached before since 1866, and the officials of the bureau were apprehensive of a record breaking week. Fortunately, the returns fell from this daily average of 106.5 to an average of 68 during the last three days, and the mortality rate of the week is only 16.50, as compared with 17.61 for the corresponding week of last year, and of 16.83 for the average February death rate of the previous decennium. There is a marked reduction in the reported deaths from the contagious diseases of childhood, from influenza and from typhoid fever, as compared with the preceding week. The respective totals of these deaths are 20 for the week and 38 for the week of February 18th. Laboratory indications point to a continued decrease of diphtheria; only 1 out of 32 cultures showed the presence of the diphtheria bacillus, while during the week before it was found in 7 cultures out of 34. On the other hand, the influenza bacillus was found in 13 of the 32 cases of suspected diphtheria, and the bacteriologists believe that influenza is frequently diagnosed as diphtheria. The protean manifestations of la grippe resemble the clinical symptoms of so many other diseases—diphtheria as closely as almost any other—that the bacterial examination is of first importance. Only 2 deaths from typhoid fever were reported, and the use of the epithet "vanishing" in connection with Chicago typhoid seems justifiable.

Pith of Current Literature

SEMAINE MEDICALE.

January 25, 1905.

Mikulicz's Disease,

By L. CHEINISSE.

Mikulicz's Disease.—Cheinisse has compiled the literature on this disease, which is one of general lymphadenitis in which the salivary and analogous glands are particularly involved.

PRESSE MEDICALE

January 28, 1905.

Opening Lecture at the Surgical Clinic at La Charité,

By Professor P. RECLUS.

Lecture.—Reclus's address was an eloquent obituary of Paul Tillaux.

January 15, 1905.

1. Operation of Nephrectomy for Cancer,

By RAYMOND GREGOIRE.

2. The Action of the Supinator Brevis in Paralysis of the Radial Nerve. Pathogeny of an Incomplete Radial Paralysis in the Leader of an Orchestra,

By GEORGES GUILLAIN and COURTELLEMENT.

1. **Nephrectomy.**—Gregoire advocates an incision in the axillary line from the costal border to the iliac crest with another incision running forward at each end 4 or 5 cm., the upper one along the margin of the thorax, the lower along the crural arch, thus forming a short flap. The chief advantage of this incision over the one in the lumbar region is that the whole of the fatty capsule of the kidney can be removed through it. Frequently the renal cancer is disseminated in the perinephritic tissues and has to be removed piece by piece.

2. **The Supinator Brevis and Paralysis of the Radial Nerve.**—Guillain and Courtellement report the case of a man, 40 years old, in whom without known cause radial paralysis of the right hand developed. First he noticed that he could not move his little finger readily, six hours later the ring finger was similarly affected and after that the paralysis increased progressively without pain or any subjective symptom. Examination revealed a very tender point on the posterior surface of the forearm at a place corresponding to the emergence of the posterior branch of the radial nerve from the supinator brevis. The writers believe that the cause of the paralysis was a neuritis of the radial nerve induced by the action of the supinator brevis in the movements of pronation and supination so frequently repeated by the patient in the practice of his profession.

LYON MEDICAL

January 22, 1905.

1. Cholecystocele and Floating Liver,

By M. L. BOUVERET.

January 22 and 29, 1905.

2. Pylorectomy,

By M. GOULLIQUOUD.

1. **Cholecystocele and Hepatoptosis.**—Bouweret reports a case in which the patient, a woman, did not complain of her liver or gall bladder, but had considerable abdominal trouble, was constipated, had mucomembranous colitis, and presented the usual symptoms of well marked enter-

optosis. During an examination a tumor was accidentally found. It grew slowly and was not always to be found in the same place. A successful operation was eventually performed.

2. **Pylorectomy.**—Goullioud is moved by the disfavor into which this operation has recently fallen to give in full detail the histories of 13 cases in which he has performed this operation. At first he performed Kocher's operation, but soon abandoned it for Billroth's, which he later modified. One patient died immediately after operation, one two months and one four months later; the balance, ten, recovered. All were operated on between March, 1899, and November, 1904, five during the latter year. There has been no recurrence of the cancer in one patient at the end of five years, in another at the end of three years and in a third at the end of eighteen months.

REVUE DE MEDECINE

January 10, 1905.

1. A Study Relating to the Alimentation of Tuberculous

Dogs,

By RICHEL.

2. A New Investigation on Clinical Cardiology,

By D'ESPIRE.

3. Experimental Tuberculosis of the Heart and the Aorta,

By BERNARD and SALOMON.

4. Renal Opotherapy (Renault-Dubois Method). Ingestion of Raw Pigs' Kidneys. Clinical Results,

By CHOUPIN.

1. **A Study Relating to Alimentation of Tuberculous Dogs.**—Richet draws the following conclusions from his investigations: 1. The expenditure in heat units of tuberculous dogs exceeds that of normal dogs by about 25 per cent. 2. In order to estimate this expenditure satisfactorily the determination should be made at the surface of the body. If the animal loses weight the heat units absorbed must be less than those expended, and we must conclude that there are heat units of denutrition. On the other hand, if the animal gains weight the heat units absorbed exceed those which are expended, and there are heat units of fixation. 3. If the number of heat units absorbed in twenty-four hours is less than twelve the animal will die, for the absorption of heat is insufficient and he is existing at the expense of his tissues. 4. The average absorption of heat units by the tuberculous dog with a mixed diet is about eighteen, but with a diet of raw meat it may be diminished to eight. 5. The minimum quantity of nitrogen per twenty-four hours which is required in the first stages of tuberculous infection is fifteen centigrammes, which corresponds to about one gramme of proteid material. 6. It follows, therefore, in respect to the alimentation of tuberculous dogs that two conditions must be satisfied; more than twelve heat units must be absorbed per diem, and more than fifteen centigrammes of nitrogen, or, in other words, a minimum daily quantity of one gramme of proteids and two grammes of hydrocarbons.

BERLINER KLINISCHE WOCHENSCHRIFT.

January 16, 1905.

1. The Influence of Alcohol Upon the Susceptibility of Rabbits Used to Cultivate Bacteria.

By C. FRAENKEL.

2. Immunization Against Tuberculosis,
By P. BAUMGARTEN and C. HEGLER.
3. The Gastric Secretion of Gastrotomized Man with Rec-
tal Feeding,
By UMBER.
4. Experimental Examinations of Gastric Juice,
By A. BICKEL.
5. The Influence of the Röntgen Rays Upon the Ovaries,
By L. HALBERSTAEDTER.
6. Aronson's Antistreptococcus Serum,
By R. KLEIN.
7. Nervous and Mental Diseases Following Electrical In-
juries (*Concluded*),
By A. EULENBURG.
8. The Infectious Paths of Pulmonary Tuberculosis,
By H. BEITZKE.

1. **Influence of Alcohol Upon Rabbits.**—Fraenkel has examined rabbits to which alcohol had been administered and which were subsequently inoculated with cholera and typhoid bacilli. It appears that a single administration of alcohol augments the susceptibility of animals inoculated with cholera, but if the alcohol administration is continued, this susceptibility is diminished. Even though the alcohol is given for some weeks, however, the capacity of the animals to furnish a serum with specific characteristics, is not diminished, but is even increased, if only to a slight degree. The experiments with typhoid yielded similar results. The author withholds his opinion as to corresponding results upon man.

2. **Immunization Against Tuberculosis.**—Baumgarten and Hegler have made attempts at immunization with the serum of a calf which had been inoculated with human tubercle bacilli; and later, five successive times, had been inoculated with virulent material from animals sick with bovine tuberculosis, without showing any noteworthy signs of disease. The serum of this calf was used prophylactically upon another calf which had been inoculated with bovine tuberculosis. Two other calves, similarly inoculated were used for control, the latter two dying of extensive tuberculosis, while the first calf remained immune.

4. **Gastric Juice.**—Bickel gives the results of his examination on the molecular concentration of the gastric juice in milk and meat diets and in pilocarpine poisoning. It appears that pilocarpine increases the secretory activity in a specific way. Experiments on dogs with mineral waters, showed that "Kochbrünnen" water given on the empty stomach increases the secretory activity of the stomach.

5. **Influence of Röntgen Rays on the Ovaries.**—Halberstaedter exposed five rabbits to the action of the Röntgen rays in such a way that the ovarian region of one side was under the influence of the rays. Macroscopically, a diminution in the size of the ovaries could be seen and microscopically, there was a disappearance of Graafian follicles. The author then examined the ovaries, in anaesthesia, of another set of rabbits before exposing them to the rays. They were then subjected to the influence of the rays and the same ovarian condition was subsequently found. The practical conclusion to be drawn is that when the Röntgen rays are used therapeutically upon women, the ovarian regions should be protected against their influence.

6. **Aronson's Antistreptococcus Serum.**—Klein reports the use of the serum in two cases. In one, a boy suffering from pleuropneumonia, severe intestinal disturbances arose, indicating a sepsis. The use of the serum created a great improvement in which the crisis of the pneumonia played no part. The second case was that of an elderly man suffering from a urogenital sepsis in which the employment of the serum brought about an immediate fall in the temperature, although the local condition continued.

8. **Pulmonary Tuberculosis.**—Beitzke affirms that the newer researches have only impressed more firmly the older views that the infection by the way of the air is the most important genetic element in pulmonary tuberculosis. The tuberculous individuals furnish the greatest source of infection. Bovine tuberculosis is also dangerous to man, and prophylaxis against tuberculosis must be directed toward these elements.

ZENTRALBLATT FUER CHIRURGIE

January 7, 1905.

1. Chloroform-Oxygen Anaesthesia,
By ROTH.
2. Phlegmone Ligneuse (Reclus),
By A. SCHMINKE.

1. **Chloroform-Oxygen Anaesthesia.**—Roth speaks warmly of anaesthesia induced by the simultaneous use of oxygen and chloroform. He records the favorable views of a number of prominent surgeons, and reports 2,000 cases of his own in which not the slightest difficulty or annoyance arose. An advantage of the method lies in the exact dosage which is possible. Roth believes the oxygen acts as an antidote to the chloroform. He is now conducting experiments along this line. He asks for statistics from other operators.

January 14, 1905.

1. Amaurosis Following Paraffin Injection for Saddle
Nose,
By W. MINTZ.

1. **Amaurosis After Paraffin Injections.**—Mintz reports the third case of this kind. The patient had a syphilitic saddle nose and one injection of forty-three grade paraffin was made for prosthetic purposes. Three minutes after the injection there was pain in the left eye followed by complete blindness, vomiting and a pulse of forty-eight. In the next few days symptoms of venous congestion appeared in the orbit—paralysis of the ocular muscles, corneal cloudiness and exophthalmos. In the neighborhood of the injection, a small gangrenous spot appeared in the skin. The author says that, since these complications can appear without our knowledge, patients should be informed of the possibilities which may follow paraffin injections.

GAZZETTA DEGLI OSPEDALI E DELLE CLINICHE.

January 15, 1905.

1. The Reducing Power of the Urine in Pleuritis Peritonitis, and Tuberculosis of the Lungs,
By AUGUSTO PLESSI.
2. The Iodine Treatment of Typhoid Fever,
By ALEARDI CERIOLI.
3. Renal Hæmaturia Probably of Traumatic Origin,
By BALDO ZANIBONI.

1. **Reducing Power of the Urine.**—Plessi studies the reducing power of urine in health and

disease. This study is intended to bring out the amount of non-oxidized substances which are present in the renal secretion and thus to determine the state of metabolism in the body. The author thinks that the method in question offers one of the best means of clinical research in conditions of altered metabolism. The relation between the amount of reducing substances in the urine and the weight of the patient furnishes a ready index to the products of incomplete oxidation. Reducing substances appear in increased amounts in the urine in pleuritis and in exudative peritonitis. During these maladies variations occur, however, in the amount of reducing substances, and the largest amount is seen when the fluid is undergoing absorption, while the smallest amount appears when the fluid is effused. The disappearance of an œdema is also accompanied by a noteworthy increase in the amount of reducing substances. These bodies are also increased in pulmonary tuberculosis, but there seems to be no relation between the amount of reducing substances, and the condition of the lung. The greatest amount of these bodies is seen in the urine of tuberculous subjects, when the general symptoms are most pronounced. The method of determining the reducing power of the urine which the present author employed is a modification of that of Helier, and was suggested by Lucatello. To one c.c. of urine are added 50 c.c. of distilled water, two c.c. of a twenty-five per cent. solution of sulphuric acid, and fifteen c.c. of a decinormal solution of potassium permanganate. The mixture is boiled for five minutes, in order to obtain the perfect oxidation of the organic substances, and then is cooled to 70°. To this are then added 15 c.c. of a decinormal solution of oxalic acid. Then the solution of permanganate is added once more, drop by drop, until its red color persists. The amount of this solution thus used indicates the reducing power of the urine. When the urine contains albumin, it should be cleared by precipitating and filtering the latter.

2. Iodine in Typhoid Fever.—Cerioli highly recommends the use of iodine in typhoid fever. He used this treatment in sixteen cases with excellent results. He gave daily doses of 7 centigrammes of iodine and 70 centigrammes of potassium iodide, administered internally in mixtures. He did not find it necessary to use injections of these drugs subcutaneously, but believes that in cases where there is imminent danger they could be used with advantage. No signs of iodism were discovered in any of the cases treated in this way. In addition, powders of quinine and sodium benzoate were given, and the usual diet was employed. In two cases only did he use ice bags over the abdomen.

RIFORMA MEDICA.

January 7, 1905.

1. On the Minute Changes in the Organs as the Result of the Injection of the Blood Serum of Heterogeneous Animals (*To be continued*). By G. R. SÆLLI.
2. On the Effects of the Resection of the Nerves of the Pancreas, By GIUSEPPE ZAMBONI.

3. On the Origin and Distribution of Elastic Tissue in Cirrhotic Livers, By GIROLAMO LEONTI.
4. On the Physiopathology of the Great Omentum, By RAFFAELE PIRRONI.

2. Rôle of the Nerves of the Pancreas.—According to Zamboni, there is very little in the literature of the functional relations of the pancreas which concerns the rôle of the nerves of this organ. Since 1888, when Martinotti for the first time removed the pancreas in dogs, a great deal of research work has been done on the gland itself, on the islands of Langerhans, etc., and on the relation of the pancreas to diabetes, but little has been done to show the exact functions of the nervous mechanism of the gland. Zamboni resected the pancreatic nerves in a series of dogs and on another series, in addition, tied portions of the gland itself at each end thereof, in order to compare the behavior of the isolated segments with that of the central portion. The dogs bore the operations well and not only did not show any signs of illness, but increased in weight. There was never any sugar in their urine. On autopsy, nothing unusual was noted in the gland in the way of lesions. The tied portions were uniformly atrophied and did not show the special resistance in the islands of Langerhans which has been described by Schultze. The blood vessels of the gland were very much dilated, even as long as six months after the operation, and their walls showed degenerative changes, except in the central portion of the pancreas. The islands of Langerhans showed important degenerative changes, and the fact that these changes occurred without producing any glycosuria, points to the supposition that these structures are not concerned in the function of the pancreas to the extent supposed. Zamboni thinks that the islands of Langerhans represent embryonal residues in the gland, or that they are structures which have a more important function in the lower vertebrates. He will discuss this question more fully in a later paper.

3. Elastic Tissue in Cirrhosis.—Girolamo found that the amount of elastic tissue in the liver varies according to the stage of the disease and the individual patient, but especially according to the amount of embryonal or new connective tissue which had been transformed into old connective tissue. The early cases usually show a distribution of the elastic tissue along the natural septa between the lobules, etc., as well as along the blood vessels. The elastic tissue along the arteries and veins runs longitudinally, while that along the biliary canals usually runs transversely to the axis of the vessel. This elastic tissue is not derived, as some have asserted, from the vessels, but is only a part of that elastic tissue in which the older forms of connective tissue are so rich.

4. Function of Omentum.—Pirroni wished to investigate the alleged functional relation between the spleen and the omentum and for this purpose removed the spleen in a series of animals and examined their omenta afterwards. As he could not gain any positive results by this means, he used the following method: He removed or tied off the spleen in a number of animals, and then injected into these animals solution of sodium

taurocholate. This is a powerful hæmolytic against which animals may be immunized by increasing the dose gradually. During this immunization the spleen becomes enlarged and the Malpighian bodies proliferate. In order to detect a connection between the functions of the spleen and those of the epiploon, the author immunized with sodium taurocholate animals deprived of the spleen, and watched whether any changes occurred in their omentums. Then he compared his findings with those appearing in animals immunized in the same way, but not deprived of the spleen. He found that the histological reaction in the omentum of the animals deprived of spleens and immunized with taurocholate was infinitely more marked than that occurring in animals with intact spleens. This reaction consisted in the production of a phagocytosis. In the animals with spleen intact this phagocytosis took place largely within the spleen, but in those in which the spleen had been removed the phagocytosis took place much more markedly in the omentum, the latter having taken up a compensatory increase of function in place of the absent spleen. In addition to its local protective function which is already known, the omentum, therefore, participates in the general work of defense in the body.

3. The Mode of Action and the Proofs of Activity of Certain Antimicrobial Serums (*To be continued*),

By A. PALADINO BLANDINI.

4. On the Minute Changes in the Organs as the Result of the Injection of Heterogeneous Serums,

By GIUSEPPE ROMANO SÆLI.

1. **Endothelia in the Blood.**—Patella, at the Congress of Padua held during the past year, reported the results of his researches which tended to show that endothelial cells exist in normal circulating blood, and that they are increased in some diseases, such as, for instance, in cases of endocarditis due to polyarthritis. These elements were flat cells with an irregular outline and with comparatively faintly staining cytoplasm as well as caryoplasm. On scraping the inner walls of arteries in animals, and dissolving the scrapings in normal salt solution, similar elements were found. Patella believes that the term "lymphocyte" has been erroneously applied to a large number of cells of the normal blood, which have deeply staining nuclei of large size and a thin area of cell body staining pale about this nucleus. True lymphocytes are the representatives of the lymphoid tissue in the blood, and are quite different from these. True lymphocytes show diametrically opposite staining qualities, and their cytoplasm is more basophile than their caryoplasm. Ehrlich was the first to describe mature and fully developed true lymphocytes. They may be seen in the juice from the centre of a lymphatic gland and in the thoracic duct. True lymphocytes are made up of a large nucleus which is weakly basophile

and of a thin rim of cytoplasm, which is markedly basophile. The nucleus shows several nucleoli (?). In the lymph these cells are derived from much smaller elements which contain a number of scattered basophile granules, and which later form the cytoplasm by crowding to the periphery and joining in a homogeneous mass. These true lymphocytes, according to Patella, are rather scarce in the normal blood, and most of what are generally termed lymphocytes are merely derivatives of endothelial cells, which are shed by the linings of the arteries, veins, and capillaries. While this hypothesis seems a little daring at first glance, the author pleads that his theory simplifies our conception of the origin of the large and medium sized mononuclear cells of the blood, and is much more probable than the other theories heretofore advanced, which for the most part are based on old pathological ideas. If the mononuclear cells in question be regarded as derivatives of endothelia, the classification of leucocytes becomes much simplified. A proof offered by Patella in support of his theory is, that after numerous unsuccessful attempts, he was able to produce in the mononuclear cells, which he claims are derived from endothelia, that peculiar reduction of silver which is known to be characteristic of endothelia in all parts of the body. He refers to the faculty of endothelial cells to reduce silver on exposure to light and to show a thin line of reduced silver in their peripheries. The presence of a large number of these endothelial corpuscles is an indication of an affection in the arteries or the heart.

2. **The Behavior of Wounded Cartilage.**—Fasoli studies the mode of repair in wounded cartilage, a subject which has received but scant attention hitherto. Microscopically, he found the following to be the process of repair: While the cells which are nearest to the margin of the wound in cartilage quickly atrophy, those a little further removed undergo proliferation, as shown by the caryocinetic changes which they undergo. After from seven to nine days, the new cells reach their maximum development. Later there are no caryocinetic figures, but there is an appreciable increase in cartilage cells along the line of incision. The matrix of the cartilage atrophies within the immediate vicinity of the injury, but a new matrix is formed from the new cells just spoken of and fills the gap. In cases in which the loss of tissue in the cartilage is slight, the repair takes place perfectly, and nothing but two lines of densely packed new cartilage cells, with an area of sparsely celled matrix between (in the line of incision), points to the existence of a wound. In other cases, where the loss of tissue is great, connective tissue derived from tendons, periosteum, or synovia forms part of the bridge that is thrown over the cartilaginous gap. Sometimes more cartilage is formed anew than is needed, and then the wound shows an exuberant projection or a series of projections.

4. **Lesions Produced by Heterogeneous Serums.**—Sæli found that the injection of heterogeneous serums into animals produces definite histological lesions in some organs, while in others

the changes which these serums occasion are much less marked. These lesions are induced quite apart from the clinical symptoms, such as fever, emaciation, loss of appetite, etc., which are observed in such animals. Well marked lesions were noted in four cases in the liver, in which a true interstitial hepatitis was found. In the spleen there was also a chronic proliferative process, but the kidneys showed a much less well marked set of lesions after injections with the serums of other species of animals. This seems to be in opposition to the opinion of Linossier and Lemoine, who in 1903 produced albuminuria in rabbits by the injection of serum from calves, and thought that this symptom was due to severe lesions in the kidneys of the animals experimented upon. The degree of the lesions produced varied according to the different species of animals dealt with. Thus the lesions produced in rabbits by the injection of the serum of dogs were much more marked than the lesions resulting in dogs in virtue of injections of the serum of bulls. The intravenous method of injection proved to be the more effective, as compared with the intraperitoneal method, inasmuch as in the former the poisons reached the tissues directly, without being first exposed to the protective and antidotal action of the organism.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

February 18, 1905

1. Chylous Ascites with Eosinophilia. An Analysis of Reported Cases, By L. NAPOLEON BOSTON.
2. The Environment and Visual Requirements of Railway Enginemen and Firemen. Personal Observations from an Engine Cab, By NELSON, MILES BLACK.
3. The Sanatorium for Incipient Pulmonary Tuberculosis. Its Aims, Methods, and Results, By FREDERICK L. HILLS.
4. Pulsating Exophthalmos; Successive Ligation of Both Common Carotid Arteries; Death, By HOWARD F. HANSELL.
5. Intermittent Exophthalmos, with Report of a Case, By WILLIAM CAMPBELL POSEY.
6. An Encouraging Case of Locomotor Ataxia, By GUY HINSDALE.
7. Immunity (*Continued*). Chapter IV.

1. **Chylous Ascites.**—Boston reports one personal case of chylous ascites with eosinophilia. He has collected and analyzed 128 cases. The results of his analysis are presented in seven tables. Complete references are given to all the reported cases. A distinction must be made between true chylous and chyloform ascites. The former affection results from the escape of chyle into the peritoneal cavity. Many pathological conditions may be responsible for the escape of the chyle. Chyloform ascites is the result of the contamination of ordinary ascitic fluid with fatty or mucoid substances derived from degenerated peritoneal cells or inflammatory exudates. The cases collected by the author belong to both these types.

4. **Pulsating Exophthalmos.**—Hansell ligated the second carotid six weeks after the ligation of the first. He felt it imperative to resort to the second ligature as soon as he did, because the

repeated retinal hæmorrhages were threatening the integrity of the eye. The patient died on the fifth day after operation. She died of cerebral anæmia, paralyzed on one side and after a period of almost continuous convulsive attacks. The general subject of pulsating exophthalmos is discussed at some length. The condition, in the majority of cases, is probably due to rupture of the carotid artery in its passage through the cavernous sinus. Up to 1898 there were one hundred and ninety-seven cases of this affection published, but the cause, course, and treatment of the condition still remain unsettled.

5. **Intermittent Exophthalmos.**—Posey reports his case in detail. There have been reported forty typical cases of this affection, and the author gives references for each. To these must be added eleven cases of venous tumors of the orbit in which, however, there was no exophthalmos present. The ætiology, pathology, symptomatology, diagnosis, and treatment of the disease are each discussed.

6. **Locomotor Ataxia.**—See this *Journal*, Vol. LXXX, page 186.

BOSTON MEDICAL AND SURGICAL JOURNAL.

February 16, 1905.

1. The Prognosis of Epilepsy, By WILLIAM ALDREN TURNER.
2. A Study of the Birth Rates, General Death Rates, and Death Rates from Cancer for the New England States for the Year 1900, By WILLIAM F. WHITNEY.
3. The Effect of Tubal Abscess Upon the Position of the Ureter, By ERNEST BOYEN YOUNG.
4. The Surgery of Meckel's Diverticulum, By JOHN W. KEEFE.
5. Perilous Calms of Appendicitis, By ROBERT WALLACE HARDON.

1. **Epilepsy.**—Turner asserts that after epilepsy has been arrested for nine years it may be assumed that a cure has been established. It must be remembered, however, that a small percentage of cases do relapse after this period. If such a definition of "cure" is granted, then it may be said that epilepsy is curable in about ten per cent. of all cases. The prognosis in any specific cases must be based on the proper appraisal of the following factors: (1) Sex; (2) inheritance; (3) age at the onset of the disease; (4) duration of the disease; (5) frequency of the seizures and, (6) character and time of the seizures. The intrinsic value of each of these factors may be stated thus: (1) Of no importance. (2) A family tendency to either epilepsy or insanity, though offering no obstacle to the arrest of the seizures in favorable cases, materially increases the likelihood of the disease becoming confirmed and the supervention of dementia. (3) Epilepsy commencing in infancy and childhood is the least favorable for arrest of the fits, and the most favorable for the production of the confirmed disease. The common type of epilepsy, or that commencing during puberty, is the most favorable form of epilepsy, both as regards the arrest of the seizures and the absence of mental infirmity. Adult

epilepsy is unfavorable, but senile epilepsy is tractable. (4) The earlier a case is brought under systematic treatment the more hopeful is the prognosis. There is a greater prospect of arrest or improvement during the first five than during the second five years of the disease. (5) The longer the interval between the attacks, the greater the prospect of arrest or improvement. (6) Cases of grand mal are more amenable to treatment than cases of petit mal. Cases of combined grand and petit mal are the least favorable. Mental deterioration is also greatest in this variety of the disease. It is least noticeable in cases of petit mal.

2. **A Statistical Study.**—Whitney concludes that it will probably be many years before the truth is known regarding the alleged increase of cancer. It is probable that the recent increased accuracy in diagnosis and registration will show that the mortality from cancer reached its height at the end of the century just closed.

3. **Tubal Abscesses.**—Young, from a study on the living as well as on the dead, concludes: (1) That small collections of pus in the Fallopian tubes do not displace the ureters. (2) That larger collections displace the ureters, (a) Outward generally, whether the ureter is above or below the mass. (b) Downward rarely, on to the posterior cul de sac. (3) That such displacements are probably due to traction upon the infiltrated broad ligaments by the distended tubes: the ureter moving with the broad ligament. (b) Direct pressure from the growing abscess, forcing the ureter in the direction of least resistance. (c) A combination of both. Previous to the investigation of this subject the operation of vaginal section has seemed a somewhat haphazard procedure, but in the light of what has been found, our lack of accidents seems quite fully explained.

4. **Meckel's Diverticulum.**—Keefe reports two cases of intraabdominal disease caused by the presence of Meckel's diverticulum. The cardinal symptoms of disease due to this persistent foetal structure are: (1) Sudden onset. (2) Pain, general abdominal and paroxysmal in character. (3) Continued vomiting. (4) Absence of feces or flatus per rectum. (5) Rapid pulse. (6) Rigidity of abdominal muscles. The treatment is purely surgical.

5. **Appendicular Inflammation.**—Hardon concludes: (1) Defervescence of symptoms and apparent better condition of a patient do not always mean recovery, but may be the forerunner of a more dangerous condition. (2) There being no specific for the disease, no matter what treatment is used, the one who procrastinates should shoulder the responsibility for the death. (3) When a clear diagnosis is made but one treatment should be advised, that of operation as soon as possible under the conditions, or the golden opportunity may be forever gone. (4) The physician who does not explain the great dangers of delay and the small comparative danger of operation is doing his patient a serious injustice, which often leads to fatal results. (5)

Operation at the proper time usually greatly shortens convalescence, and eliminates all danger from this cause hereafter. (6) Procrastination is the greatest cause of surgical deaths, operation often being performed as a last resort, when but little hope of recovery exists.

MEDICAL NEWS.

February 18, 1905.

1. Intrapleural Complications in Pulmonary Tuberculosis, By S. G. BONNEY.
2. Observations on Twenty-eight Cases of Prostatectomy, By J. BENTLEY SQUIER.
3. The Opium Question in the Philippines, By JAMES A. LE ROY.
4. Some So Called Rheumatisms, By JAMES J. WALSH.
5. Case of Primary Malignant Tumor of the Lung, By MAURICE PACKARD.
6. Calculi in Blandin's and Submaxillary Glands. Reports of Cases, By HERMAN JARECKY.
7. Prognosis and Treatment of Chronic Nephritis, By A. C. MORGAN.

1. **Tuberculosis.**—Bonney considers the following possible intrapleural complications of tuberculosis: (1) Pleurisy with serous effusion; (2) empyema; (3) pneumothorax; (4) pneumopyothorax. The symptomatology and treatment of these complications are reviewed. The author does not claim that anything new will be found in his paper.

2. **Prostatectomy.**—Squier is an advocate of the perineal route for performing prostatectomy. Seven of his patients were operated upon by the suprapubic method (three died) and twenty-one by the perineal route (two died). The paper is devoted specially to the consideration of the after-treatment which, in the author's opinion, is of more importance than the operative methods usually reported.

3. **Opium in the Philippines.**—Le Roy gives, in condensed form, the conclusions reached by the special committee appointed to study the question of regulating the sale of opium in the Philippines. This committee was composed of Major E. C. Carter, Bishop W. P. Brent, and Dr. Jose Albert. The general policy recommended may be said to consist of government monopoly of the opium trade to be followed gradually by progressive prohibition. The methods by which these ends are to be finally attained are indicated.

4. **So Called Rheumatism.**—Walsh insists that rheumatism is a much abused term. His paper is an elaboration of the idea that much of the so called uric acid diathesis with the consequent rheumatic pains is nothing more than neuritis of various kinds due to overexertion, pressure upon nerve trunks preventing proper nutrition, the presence of irritant substances in the blood, such as alcohol, lead, and the blood disturbances of diabetes and to some inherited weakness of special sets of nerves.

6. **Calculi in Glands.**—Jarecky reports the following cases: (1) Calculus in Blandin's duct associated with one in Wharton's duct. (2) Calculus in Wharton's duct attaining a large size with-

out symptoms. (3) Small calculus with intermittent swelling of submaxillary gland. These cases teach that in every case of swelling of doubtful diagnosis beneath or around the angle of the jaw, a routine examination of the floor of the mouth should be made. A calculus would then be easily discovered, and the patient saved the annoyance of any unnecessary treatment or the worry of supposed malignancy.

MEDICAL RECORD.

February 18, 1905.

1. A Report of Eighty-four Operations on the Kidney and Ureter, By GEORGE EMERSON BREWER.
2. Standardized Gruels: an Application of the Percentage Principle to Gruel Feeding, By HENRY DWIGHT CHAPIN.
3. Traumatic Rupture of the Intestine Without Injury to the Abdominal Wall, By CARLETON P. FLINT.
4. Fresh Cold Air Treatment of Pneumonia in Infants and Children, By W. P. NORTHRUP.
5. Preventive Medicine: a Study in Education, By LAWRENCE T. ROYSTER.

1. Operations on the Kidney and Ureters.—Brewer reports eighty-four operations performed during the past ten years. Nine were performed in the first five years, while thirty-nine were performed in the past twelve months. In these eighty-four cases there were twenty-seven nephrotomies, with eight deaths; twenty-seven nephrectomies with one death; nine nephrorrhaphies with no mortality; ten decapsulations on five patients, with two deaths; five operations on the pelvic portion of the ureter without a death, and six emergency operations on traumatic cases with one death. The more important and illustrative cases are reported in detail. Among the points emphasized by the author are the following: (1) The difficulty of making a correct diagnosis in cases of suspected stone. For example, stone was suspected in thirty-six cases and found in only twenty-one. In nine of these latter cases adequate explanations for the symptoms were found. In six cases no lesions were found. The author reviews the symptomatology and physical diagnosis of stone in the kidney or ureter. (2) Decapsulation of the kidney for chronic nephritis (ten operations on five subjects) has not led to recovery in any of the author's cases. (3) All cases of severe contusions of the flank followed by hæmaturia should be immediately explored. Extensive injury to the kidney may exist with only slight local and general symptoms.

3. Rupture of the Intestines.—Flint has studied a number of cases of traumatic rupture of the intestine in which there was no injury to the abdominal wall. Two personal cases are reported in full. The author considers the symptomatology and diagnosis of these often obscure cases. The paper may be summarized thus: (1) Any injury to the abdomen may be associated with damage to the intestine or other viscera. (2) An exploratory operation is justifiable in cases with distinct rigidity. (3) An operation is absolutely indicated when there is, besides rigidity, pain, tenderness, vomiting, shock, dulness, or

other symptoms indicative of some intraabdominal disturbance. (4) Cases not operated in are lost. (5) The importance of early operation cannot be emphasized too strongly. (6) At present the death rate is about 75 to 80 per cent. (7) When a greater proportion are operated upon early, the death rate will be much lower.

4. Pneumonia in Infants and Children.—Northrup insists on the value of fresh air in the treatment of pneumonia in children and infants. He ends his paper with the same conclusions set forth in a paper in the *Medical News*, April 30, 1904, and which we reproduced in our issue of May 7, 1904.

AMERICAN MEDICINE.

February 18, 1905.

1. The History and Development of Surgery During the Past Century (*Concluded*), By FREDERIC S. DENNIS.
2. Kidney Diseases Requiring Surgical Interference, By J. M. BALDY.
3. The Extraction of Cataract: Choice of Operation Based Upon Intraocular Conditions, By S. D. RISLEY.
4. The Efficiency of Copper Foil in Destroying Typhoid and Colon Bacilli in Water, By HENRY KRAEMER.
5. Classification of Gastric Ulcers, By A. L. BENEDICT.
6. Treatment of Strangulated Hernia in the Very Old, By DAVID PEYTON.
7. Some Medical and Sanitary Experiences in a Portion of the Philippines, By BENJAMIN J. EDGER, JR.

2. Kidney Disease.—Baldy asserts that not infrequently kidney disease gives rise to misleading symptoms. Five illustrative cases are reported. In two the symptoms were gastrointestinal and nervous, while the responsible lesion was floating kidney. One case of cystic kidney with a well defined adenoma on its surface was taken for ovarian disease, one case of calculus of the kidney and ureter was mistaken for and operated upon for an ovarian and uterine growth, and a tuberculous kidney and ureter was mistaken for a pyosalpinx. All five cases came finally to operations on the kidneys with good surgical recoveries. Ordinarily the kidney lesion should not be overlooked, and in the majority of the cases reported by the author ordinary care would have made the mistakes reported impossible.

4. Disinfection by Copper Foil.—Kraemer, from a series of experiments conducted for the purpose of determining the efficiency of copper foil in destroying typhoid and colon bacilli in water, draws the following conclusions: (1) The intestinal bacteria, like colon and typhoid, are completely destroyed by placing clean copper foil in the water containing them. (2) The effects of colloidal copper and copper sulphate in the purification of drinking water are in a quantitative sense much like those of filtration, only the organisms are completely destroyed. (3) Pending the introduction of the copper treatment of water on a large scale the householder may avail himself of a method for the purification of drinking water by the use of strips of copper foil about $3\frac{1}{2}$ inches square to each quart of water, this being allowed to stand over night, or from six to eight

hours, at the ordinary temperature, and then the water drawn off or the copper foil removed.

5. **Gastric Ulcer.**—Benedict offers the following classification of gastric ulcers: (1) Peptic ulcer. (2) Erosions by chemical and thermic caustics, as in corrosive poisoning and ingestion of liquids at or above 60° C. (3) Ulcer due to organic vascular lesions, such as embolism, thrombosis, or obliterative inflammation of a vessel. (4) Catarrhal ulcers are with doubtful propriety separated from the last category, as they occur in chronically inflamed and degenerated stomachs which present minor degrees of vascular disease. (5) Varicose ulceration, analogous to the external condition of the same name, is usually due to portal obstruction and specially to that dependent upon hepatic sclerosis. (6) Toxæmic diapedesis, with a tendency to actual rhexis. (7) Vicious menstruation. (8) Gangrenous ulceration. (9) Phlegmonous ulceration of the stomach. (10) Specific ulcer. (11) Traumatic ulcerations.

ARCHIVES OF THE ROENTGEN RAY.

No. 54, 1905.

1. The Dangers of the X Rays, By FRANKLIN.
2. Phototherapy, By KING.
3. X Rays in the Treatment of the Pruriginous Dermatoses, By BELOT.
4. The Use of Hydroelectric Methods in Medical Practice, By WHITAKER.

1. **The Dangers of the X Rays.**—Franklin has made use of the following expedients to avoid the injuries which may attend x ray practice: 1. Every patient is placed in a recumbent position on the operating table, no matter where the lesion may be located, and is protected with sheets of lead foil. A separate mask is supplied for each patient, with an aperture which permits only the exposure of the lesion. This protects the patient from injury when unavoidable movements are made. 2. The exposures are of a definite potency in accordance with the author's method of radiometry. The potency is small at the beginning, and is gradually increased to the desired point. 3. With regard to the operator the added aggravation of developing solutions should be obviated by the use of rubber gloves. The physiological effects of the x rays are now so reasonably certain that untoward effects ought not to be expected in the hands of competent operators. With the general adoption of the radiometric technics described by the author the last and greatest danger of the x rays will have been eliminated.

2. **Phototherapy.**—King speaks of the electric arc and other forms of light which are used in phototherapy. The electric arc which is so useful in lupus and similar affections requires specially constructed lenses for collecting the rays, and compressors for blanching the diseased tissues, thus rendering them more susceptible to the effect of the ultraviolet rays. The intensity of the light from the Finsen lamp is such that it would burn the tissues were not the heat rays eliminated, and the chemical rays alone permit-

ted to traverse the tissues. The author has treated a great variety of diseases by means of light, especially skin diseases, including those which are malignant. His success has been sufficient to make him a believer in its efficacy. He believes that results from this mode of treatment depend partly upon the susceptibility of the tissues, in each case, and partly upon the technics of the physician. He recognizes that the present technics is still imperfect, and that there is also room for instruments of greater efficiency.

3. **X Rays in the Treatment of Pruriginous Dermatoses.**—Belot concludes as follows: 1. The skin should absorb as quickly as possible the quantity of rays necessary for a cure, provided always that this quantity is compatible with the maintenance of the integrity of the skin. If this should not be possible the maximum dosage that can be employed with safety should be administered at each session or series of sessions. 2. An interval of fifteen or twenty days should elapse between any two applications. 3. Treatment should not be resumed until the reaction has nearly or quite subsided, the relative condition of the tissues and the lesion being the guide as to the dosage to be administered. By observing the foregoing method the author has entirely avoided the production of severe accidents in all the 150 cases which he has treated by radiotherapy.

LANCET.

February 4, 1905.

1. The Infectivity and Management of Scarlet Fever, By W. T. G. PUGH.
2. Primary Heart Failure as the Immediate Cause of Death in Acute Diphtheritic Toxæmia, By C. BOLTON.
3. The Cancer Problem, By J. BEARD.
4. The Characters of Bacillus Coli as an Indicator of Excretal Contamination, By W. G. SAVAGE.
5. A Case of Typhoid Fever Presenting Some Unusual Features, By K. ANDERSON.
6. Hydatid Cyst Simulating Subphrenic Abscess, By J. P. PARKINSON.
7. The Prognostic Value of the Diazo Reaction in Enteric Fever, By J. D. ROLLESTON.
8. The Army Medical Service of the Argentine Republic, By F. HOWARD.

1. **Scarlet Fever.**—Pugh states that the infective agent in scarlet fever has been proved definitely to be present in the throat, and not infrequently in the nasal cavities also. The bacterial poison exhibits a selective action, affecting the kidneys and the superficial layers of the skin, resulting in desquamation, but in all probability the desquamating cuticle is not infective. As in diphtheria, it is impossible to ascertain definitely by clinical means when the patient has been freed from infection. It is probable, however, that the majority of patients are free from infection at the end of the minimum period of isolation usually prescribed; six weeks. Transmission of infection is especially liable to occur from those who suffer or have suffered from rhinitis, and a nasal discharge is always to be viewed with suspicion. The conditions necessary for the trans-

mission of the disease are the following: The contagium must be present in a form capable of being carried; there must be a vehicle for its conveyance; it must be actually conveyed to a mucous membrane; the germ must be still virulent when received; the dose must be sufficiently large; and the receiver must be susceptible to infection. The author favors hospital treatment, especially among the poorer classes. Among the drawbacks of segregation, however, are the following: 1. The risk, in case of a wrong diagnosis, of the patient's acquiring scarlet fever. 2. The possibility of secondary infection with some other disease. 3. The longer period of isolation. 4. Differences in virulence of cases in the same ward, with resulting detriment to the milder cases. 5. Detention because of simple rhinitis. 6. Reinfection. 7. The occurrence of "return" cases on the patient's return home.

2. **Heart Failure in Diphtheria.**—Bolton recalls Ehrlich's demonstration that diphtheria toxine consists of two bodies: (1) toxine, giving rise to the acute symptoms of poisoning; and (2) toxone, which leads to degeneration of the peripheral nerves after the acute symptoms have subsided. So that diphtheria itself may be divided into two stages: (1) An acute toxic stage, due to toxine; and (2) a convalescent stage, during which paralytic phenomena develop as a result of the action of toxone. Death in acute diphtheria toxæmia is due to primary heart failure, and to account for this extensive fatty degeneration is found in the heart and acute degeneration in the motor nucleus of the vagus. It is quite likely that the acute changes in the vagus nucleus produce irritation or paralysis of the vagus, one or the other action predominating at different times. Greatly varying irregularity of action is usually the prominent feature; and the pulse may be either abnormally slow or rapid. So that the fatal syncope of acute diphtheritic toxæmia is therefore due to the disturbed innervation of an acutely degenerate heart. At a later stage of the disease interstitial cellular inflammation combines with the above changes to produce a latent weakness of the heart which can be brought into evidence by some strain.

3. **Cancer.**—Beard holds that malignant neoplasms are trophoblastomata—*i. e.*, pathological manifestations of the asexual portion (trophoblast) of the life cycle and sometimes attempting to repeat the germ cell portion of the life cycle. They never include or repeat any portion of an embryo, thus differing from the benign neoplasms (embryomata). They are never composed of "somatic" or "embryonic" cells, though they may mimic such. They erode and destroy normal cells and tissues by a superior power of digestion; *i. e.*, they produce an enzyme which is more powerful than the enzyme of normal tissues. So that our problem now is to discover the antithesis of this pathological enzyme, one which can destroy it and so lead to degeneration of the tumor by simple atrophy.

4. **Bacillus Coli.**—Savage has studied the colon bacillus as an indicator of excretal con-

tamination. It is admitted that the presence in water of this organism means that the water has been contaminated with sewage. The essential characters of a typical bacillus coli are also agreed upon. But how far may an organism deviate from this typical standard, and yet have an equal significance as a test for excretal contamination? The author discusses the various morphological and cultural characters of the organism, bringing out the following points: *Motility.* All true colon bacilli are motile, but when isolated they may not exhibit any motility. *Liquefaction.* All liquefiers of gelatin should be excluded. *Colonies.* The types of the colonies may vary because of environment or acquired characters. Usually they are quite typical. *Indol.* An organism normal in all respects except that it does not produce indol should not be rejected until after several weeks' growth in the laboratory and again testing in fresh peptone water, it still fails to produce indol. *Acid.* Production of acid in litmus whey or milk is a constantly present character of bacillus coli communis. *Milk Coagulation.* This is due to the formation of acid and is a stable and but very little variable characteristic. *Glucose.* All true bacilli coli ferment glucose and lactose with the formation of acid and gas. Many organisms ferment glucose, but not lactose. The author looks on the fermentation of lactose as the most important differentiating character of the colon bacillus.

7. **The Diazo Reaction.**—Rolleston has investigated the prognostic value of the diazo reaction of Ehrlich in typhoid fever, and reaches the following conclusions: (1) In all but severe attacks the diazo reaction tends to disappear in the course of the second or third week, this disappearance shortly preceding, or coinciding with the commencement of lysis. (2) Its reappearance during or after the completion of lysis is a warning of recrudescence or relapse, or of complications directly due to the specific bacillus. (3) A sudden disappearance of the reaction associated with a deterioration of the general condition is of bad omen. (4) The character of the reaction is a useful check to the history.

6. The Relations of Medical Men to Each Other: An Introduction to a Discussion on Medical Ethics, By R. MACLAREN.
7. The Calculation of the Date of Delivery in Pregnancy, By W. J. CAIE.
8. Scrofulous Ulcers of the Legs (Bazin's Malady). Successfully Treated by High Frequency Currents, By W. F. SOMERVILLE.

9. The Corneal Reflex the Most Reliable Guide in Anæsthesia,
By H. B. GARDNER.
10. Some Points in the Treatment of Brachialgia and Sciatica,
By J. E. HARBURN.
11. Case of Precocious Puberty in a Female Cretin,
By F. W. KENDLE.

1. **Scarlet Fever, Measles, Etc.**—Poynton discusses the diagnosis of scarlet fever, rubella, and measles. In scarlet fever the difficulty is not with the severe cases, but with the mild ones. The author is not yet convinced that the disease is not to be transmitted by desquamation: as long as the real cause of scarlet fever is unknown we are not justified in experimenting upon this point. Some physicians hold that influenza may be associated with rashes very closely resembling those of scarlet fever; the same is true of dengue fever. In German measles there are two types of exanthem: the morbilliform, which is more common and characteristic, and the scarlatiniform. Both last two or three days, are apt to itch, and may be followed by a fine branny desquamation. The most constant sequela is the occurrence of a secondary sore throat about the fifth day. As regards Dukes's so called "fourth disease," an epidemic rubella usually classed under rubella, the author holds that its existence has not yet been proved, although he does not deny the possibility of its existence. He calls attention to the great value of Koplik's spots in the diagnosis of measles: they are found in ninety-seven per cent. of the cases. The measles of the poor is much more severe than that of the rich. Never crowd cases of measles together: if it is absolutely necessary, then pick out the cases of bronchopneumonia, as otherwise it will spread fast among them.

2. **Prodromal Rashes of Measles.**—Rolleston summarizes the general characteristics of the prodromal rashes of measles as follows: 1. The great majority of them appear within the first two days of the disease. Frequently they precede the catarrhal symptoms, Koplik's spots, and the characteristic stomatitis. 2. They are usually very transient, which accounts for the scanty attention they have hitherto received. The scarlatiniform eruptions, however, may last for a day and a night, and the isolated macules and papules even longer. 3. They have a strong tendency to be localized. Even the scarlatiniform rashes, which are the most widely diffused, seldom occupy the same extent as the fully developed rash of scarlet fever. 4. Their distribution is capricious, no special situation being affected. 5. Highly characteristic is the simultaneous association of several varieties of eruption. Accidental eruptions also occur in the other acute exanthemata—*e. g.*, scarlet fever—but coexist or follow, instead of preceding the specific efflorescence. 6. The prodromal eruptions of measles are strikingly free from any symptoms of cutaneous irritation. There is no pain or pruritus, nor is there any subsequent desquamation. 7. Unlike in the case of smallpox, initial rashes appear to be of no aid in prognosis in measles. 8. The occurrence of such rashes as are here de-

scribed, in an epidemic focus, should arouse suspicion, and prompt examination should be made of the buccal mucosa for Koplik's spots and the characteristic stomatitis.

3. **Fibroid Pneumonia.**—Auld reports a case of fibroid pneumonia in a child eight years of age. It is a peculiar form of pulmonary induration which succeeds acute pneumonia. Many authorities deny that fibrosis can occur in such cases unless some definite lesion of chronic inflammatory character already exists. The author suggests that in these cases the antibacterial and antitoxic bodies are insufficiently produced, or their action is disturbed. The disease is febrile, it is pneumonic, and it is fibroid, hence it is a fibroid pneumonia. It may begin very acutely or subacutely, and though always rare, is more liable to attack lungs already injured.

4. **Lobar Pneumonia in Measles.**—Bottomley has observed thirteen cases of lobar pneumonia following measles, instead of the usual bronchopneumonia. The onset was sudden without bronchitis, and the outcome was usually favorable. In all the cases the pneumonia appeared before the rash had faded. In all cases one or both lower lobes were affected. The duration of the disease in the unilateral cases was from five to eight days: in the others up to three weeks. The temperature rarely rose above 102° F. In only one case was there delayed resolution. Only one case proved fatal, that of a boy aged eighteen months, who died of convulsions two days after the crisis. During the same period only three cases of bronchopneumonia following measles were seen, all dying.

7. **Date of Delivery.**—Caie finds that if Naegeli's method of calculating the date of delivery in pregnancy be used, a nearer approximation of the date may be obtained if only five days be added instead of seven. Löwenhardt's method is more accurate than Naegeli's. It consists in counting the number of days between the last preceding menstrual period and the one preceding that and multiplying by ten. The date can then be got by tables.

8. **Bazin's Disease.**—Somerville reports a case of Bazin's disease in a girl aged eleven years: it is a manifestation of scrofula occurring mostly in young women, in which multiple ulcers, the consequence of a subcutaneous and self-infective inflammation, occur on the legs. The ulcers are difficult of cure, prone to relapse, and are likely to be mistaken for syphilis. An apparently lasting and perfect cure was brought about by the use of high frequency currents.

9. **Corneal Reflex in Anæsthesia.**—Gardner states that in producing anæsthesia the corneal reflex should never be completely abolished, for then the fourth stage of dangerous anæsthesia has been entered, and the next centres to become paralyzed will be those automatically controlling respiratory and cardiac action. So that the dosage of the anæsthetic should be just sufficient to maintain the condition of a dulled, but not absent corneal reflex.

Letters to the Editor.

THE ABDOMINAL PLASTER BANDAGE.

113 HANCOCK STREET,

BROOKLYN, January 28, 1905.

To the Editor,

Sir: I should like to add a word or two in the praise of the plaster bandage of Dr. Rose. I had the good fortune to be working in the dispensary of the Post-Graduate Hospital with Dr. Rose at the time he was first using this form of abdominal support, some five years ago, and have used it in every suitable case since that time, and with almost uniformly good results. In a paper on Mucous Colic which I read before the Brooklyn Medical Society last spring, to which Dr. Kemp added much by his most interesting remarks in the discussion, I mentioned, with due credit to Dr. Rose, this method of abdominal strapping. I use simply two or more layers of straps, each two inches in width, instead of the large pieces formerly employed, and find that it is less bulky and more agreeable to the majority of persons when employed in this manner. While I am not, perhaps, quite so optimistic as to the virtues of any form of abdominal support as the author of the method in question, I believe that where a bandage is indicated the plaster is the best form to be employed.

H. W. LINCOLN.

A DISCLAIMER OF APPARENT DISCREDIT.

65 EAST NINETIETH STREET,

NEW YORK, February 8, 1905.

To the Editor,

Sir: In your issue for December 17, 1904, in my paper entitled Clinical Observations in Scarlet Fever, with Special Reference to the Heart and Other Complications, and Therapeutic Suggestions, the case of Elaine K. is reported by me. This case was under the treatment of a physician for between two and three weeks when complications developed, and the family recognized the neglect of the attending physician, whom they believed responsible for the development of the complications, and dismissed him. Dr. Marvin Pechner then was asked to take charge of the case. Since the publication of my paper my attention has been directed by several physicians to the fact that as the article appears it reflects discredit on Dr. Pechner. Just the reverse is the case. I write to ask you to allow me to give Dr. Pechner full credit for the careful after-treatment of the case, which might have ended fatally but for his vigilance.

LOUIS FISCHER.

CHLOROFORM AND FLAME.

267 WEST ONE HUNDRED AND FOURTEENTH STREET,

NEW YORK, February 11, 1905.

To the Editor,

Sir: I read with considerable interest the editorial, Chloroform Vapor and the Flame of Illuminating Gas, as I have been the victim of the combination quite a number of times. I have called the attention of a number of my medical

friends to the fact and they expressed surprise. It affects me by producing violent paroxysms of coughing with retching. I have not noticed any other symptoms, but shall watch in the future to see if there are any. I usually get relief by taking a dose of atropine sulphate, $\frac{1}{100}$ of a grain, and going into the external air. Upon the last occasion I held off the paroxysm (I thought) by sipping hot water and holding some in my mouth. The use of chloroform by daylight, electric light, or oil light does not affect me. I have had it administered to myself in daylight and noticed that it did not affect me thus. I have not seen any of the other persons present affected as I have been. I am particularly free from any nose, throat, laryngeal, or bronchial trouble. I should like to find some preventive, as it has interfered considerably with my work.

ROBERT W. REID.

Proceedings of Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of January 25, 1905.

The President, Dr. JAMES M. ANDERS, in the Chair.

Specimens Illustrating the Need of Early Operation in Surgical Diseases of the Abdomen.

—Dr. JOHN B. ROBERTS exhibited these specimens, the first of which was one of stricture of the sigmoid flexure due to ulceration of the mucous membrane. A diagnosis of obstruction of the gastrointestinal canal in the neighborhood of the pylorus and duodenum was made. The condition of the patient was so bad that jejunostomy alone seemed possible. This was done for the purpose of feeding the patient prior to a more extensive examination of the abdomen and operative relief of the condition found. Death occurred after a few days, from exhaustion. It was then found that the obstruction was in the sigmoid flexure. Early operative relief would almost certainly have been accomplished by intestinal anastomosis.

The second specimen showed a perforating duodenal ulcer close to the pylorus. A time for operation was appointed, but before the operation was done perforation occurred. An immediate operation was then advised as a last resort, but the patient and his friends would not consent. Dr. Roberts believed there was little doubt that gastrojejunostomy done a day or two prior to the time of perforation would have saved this patient's life.

Specimen No. 3 was a perforated appendix removed from a patient who had come under Dr. Roberts's care about forty hours after an attack of abdominal pain. When he saw the man his pulse was 160 and very feeble. His hands were cold, his face was covered with a clammy sweat, and the abdomen was distended and painful. Believing that an operation would almost certainly result in death, Dr. Roberts abstained from even opening the abdomen. The autopsy showed the lower abdomen full of pus, with a gangrenous opening in the appendix big enough to admit a lead pencil.

The fourth specimen was a large gallstone, measuring an inch and a half by three quarters of an inch, from the gall bladder of a woman who had suffered for a number of years with repeated attacks of pain in the region of the gall bladder. The operation showed the stomach, gall bladder, liver, and omentum to be bound together by old and firm adhesions. The gall bladder was dragged backward until its fundus pointed toward the spinal column. It was entirely filled by this large stone. The patient had in addition a bent and adherent appendix from former attacks of inflammation. The gall bladder was opened, and the calculus removed only with great difficulty, and the appendix was excised. Drainage through the lumbar region was employed and a large drainage tube introduced through the abdominal incision. The patient did moderately well for about two days, and then died from asthenia. The case illustrated the importance of cholecystotomy in the early stage of all cases of gallstone disease.

The fifth specimen was a globular gallstone, about three quarters of an inch in diameter, removed from the junction of the hepatic, cystic, and common gall ducts. The patient had great pain and persistent jaundice, which at the time of the operation gave her a dark bronze color. Cholecystotomy was required for the extraction of the stone, and was followed by hepatic and abdominal drainage.

The specimens were shown to call attention to the importance of operating early upon gall bladder disease, inflammations of the appendix, and obscure lesions of the stomach and intestines. Dr. Roberts believed that the best results would undoubtedly be obtained in such cases by early exploratory incision, followed by operations for relief, even if such surgical methods were employed before a definite diagnosis could be made. He stated that the profession and the public should realize that this was the teaching of modern surgery.

Dr. L. J. HAMMOND agreed with Dr. Roberts upon the importance of an early operation, but said he had not yet learned how to convince patients of this importance. He attributed the delay in operation not always to the surgeon or physician, but very frequently to the patient, who went from surgeon to surgeon and from hospital to hospital with fatal results.

A New Saw Especially Adapted to Cranial Surgery.—Dr. H. C. MASLAND exhibited a saw which seemed to solve the problem of being able to open the skull with safety, celerity, and the most promising likelihood of prompt recovery with replacement of the bone flap in a vital condition. The instrument consisted of a heavy handle to overcome vibration, a circular saw attached to a short shaft connecting with the flexible shaft of an electric motor or dental engine, and a guard accurately regulating the depth of the cut. If one used either a detachable inner guard or a separate curved guard held by the left hand, all irregularities in the thickness of the bone were divided with impunity. The saw made a cut but one millimetre wide, guaranteeing a minimum waste of bone and replacement without sinking. The original opening could be enlarged by making additional bone flaps.

Dr. ROBERTS said the saw seemed to him to be a very efficient instrument. He agreed with Dr. Mas-

land that it did not need the guard, since in cutting through bone it was easy to tell by the feel when one got through. The rapidity with which the skull had been cut through showed, he thought, how much the instrument would lessen the time of operation and reduce the time the patient would be under ether.

Dr. T. H. WEISENBURG did not agree with Dr. Masland that it was not necessary to have the saw set to cut bone thicker than a quarter of an inch, since he had seen some skulls in which a deeper cut was required. Neither did he agree that it was not necessary to have a circular incision. The circular flap in his opinion was more easily replaced and was better for cosmetic reasons. He further disagreed with Dr. Masland in regard to the matter of time, and referred to Dr. Frazier's operations in the University Hospital, in which he opened the skull in two minutes and seldom exceeded three or four minutes, which he scarcely thought could be improved upon.

Dr. MASLAND referred to the instrument used by Dr. Frazier. The width of incision made by that instrument he understood to be an eighth of an inch at least, which he did not think offered as great probability of union through the line of incision as a cut one millimetre in width made by the saw which he had exhibited. This guaranteed a minimum waste of bone and replacement without sinking.

The Limitations and Possibilities of Electricity in the Treatment of Diseases of Women.—Dr.

BARTON COOKE HIRST presented this paper, which was read by the secretary. Dr. Hirst had found of late years an advantage in the use of galvanism and faradism in a limited number of conditions among the diseases of women. As a hæmostatic agent in uncomplicated small fibroid tumors, with no other symptoms than metrorrhagia, he regarded it as one of the most efficient possessed by the medical profession. He found it peculiarly useful in the treatment of amenorrhœa and sterility, the result of imperfect development or atrophy of the uterus. Two illustrative cases were reported in which normal menstruation was restored and conception occurred after the use of this treatment. In one woman there had been amenorrhœa for a year. In the other the menstruation had been reduced to a scanty discharge lasting less than a day as a result of lactation atrophy. The third indication was to restore tone to a parietic sphincter ani muscle after its restoration by surgical means, in cases in which repeated attempts had been made to restore the muscle, with failure, and in which there had been no contractile power exercised for a number of years. A fourth indication for the use of electric currents was found in certain types of dysmenorrhœa associated with an ill developed uterus. Local treatment, however, he believed, was very rarely practicable in such cases.

This limited number of conditions, Dr. Hirst said, comprised all in which it could be hoped to accomplish much by electricity. He disclaimed any intention of discussing the newer developments of electric treatment, such as the use of the x rays, the ultra violet rays, and high frequency currents.

The Toxic Changes in the Brain and Spinal Cord Due to Carcinoma.—Dr. T. H. WEISENBURG said that the influence of carcinoma of parts other than the brain and spinal cord upon the nervous

system was becoming better recognized. Metastasis might occur in the brain, either in the form of a tumor or that of an infiltration of cancer cells with the pia of the cortex or of the base of the brain. A case was recorded where basal syphilis had been diagnosed, but at the autopsy a metastatic cancer was found. This taught that whenever cerebral symptoms occurred in the course of carcinoma, no matter in what form they appeared, metastasis should be thought of in the diagnosis. In the spinal cord, metastasis generally involved the vertebrae, causing a pressure myelitis.

Cases were recorded where during the course of the disease such symptoms as mental apathy, dementia, hemiplegia, and aphasia occurred. These were undoubtedly of toxic origin. Instances had been recorded by the writer of bulbar symptoms and dementia. In these cases a careful microscopical examination of the brain and spinal cord demonstrated alterations in the nerve cells of the medulla oblongata and pons. In another case, where there were no cerebral symptoms, changes were also found in the nerve cells of the cortex. Such findings had not previously been recorded.

Book Notices.

Atlas and Epitome of Operative Ophthalmology.

By Prof. Dr. O. HAAB, of Zurich. Authorized Translation from the German with Editorial Notes and Additions. Edited by G. E. DE SCHWEINITZ, A. M., M. D., Professor of Ophthalmology in the University of Pennsylvania, etc. With 30 Colored Lithographic Plates and 154 Text Cuts. Philadelphia: W. B. Saunders & Co., 1905. Pp. 377.

It is difficult for a surgeon accustomed for years to the sight of patients undergoing operation to estimate how much or how valuable assistance will be given one of less experience by lifelike representations of single steps. Each of these pictures presents the *tout ensemble* of an operation at a particular stage, and it would seem as though a study of them would be of great service to the inexperienced surgeon. Certainly they cannot confuse one, unless it may happen that they conflict with preconceived erroneous ideas, when they would furnish valuable correction to those ideas.

The work is very brief to cover so large a subject. Over 60 pages are devoted to general considerations, the care of hospital wards and operating rooms, anesthesia, antiseptics, dressings, and instruments, and about 300 pages to operations. In places the work resembles an autobiography. The account of the author's early struggles to engraft antiseptics upon ophthalmic surgery arouses our enthusiasm, even though we feel that he is perhaps lagging a little behind now when he states that he is still using for preliminary cleansing of the conjunctival sac a bichloride solution of 1 to 5,000 and in suspicious cases 1 to 1,000, and that he keeps his instruments in a three per cent. solution of carbolic acid and returns them to the solution during the operation. This was the almost universal custom in general surgery twenty years ago, but since then both the general and the special surgeon have learned that

sepsis may be guarded against equally well by less irritating means. But Professor Haab is ever practical and his methods are sound and good, even though we may make gentle criticisms. His descriptions of operative technics are excellent and the severest criticism that can be made of them is that the limitations of space cause many of them to be too brief to be readily and thoroughly comprehended.

Miscellany.

Dr. Osler's Address to the Canadian Club.—Dr. William Osler, according to the *Canadian Practitioner*, for January, 1905, addressed the Canadian Club of Toronto at their luncheon on December 29th. The reception to Professor Osler by the four hundred members who were present was most enthusiastic.

Professor Osler, who was introduced as one who had become the first physician within the British Empire, was received with loud cheers. He addressed his hearers as fellow countrymen, and said it always gave him great satisfaction to return to his old town, where he had received his early education, and where he had so many friends. Taking up the serious part of his subject, Dr. Osler said, as Canadians they had three relations to consider—the country to the south, the motherland, and their own Canada. Fortunately, or unfortunately, the nation to the south was one of the most powerful on earth. A Briton should be proud of it, for no other nation, ancient or modern, ever had such a child.

A very serious and important influence was that of gravitation, the attraction of the larger body upon the smaller, which caused an incessant dribbling over the border of their young men. A million Canadians were in the States, many in prominent positions in finance, and in the professions, particularly in medicine and theology. There they had been successful by reason of two special qualities, industry and thoroughness, the only qualities worth anything in the make-up of a young man. If it were only in the matter of draining away the young men, it would make no difference, as plenty were left to run the country. But a more serious loss was that of the young women. He had a patient once, a neurasthenic young man of thirty or so, whose heart was not settled. Dr. Osler asked him why he did not get married. "Because all the girls I wanted have gone to the States," was the reply. Of 651 women engaged in nursing in six of the great eastern hospitals, 196 were Canadians, an enormous proportion, almost one third.

"Something should be done," said Dr. Osler, to stop the loss of the mothers of the country. He suggested two ways. Introduce a tax on bachelors. At twenty-five or twenty-six, the man who had not a family to support ought to be helping the other fellow, and such a tax would be a reasonable and rational political measure. The other way was an export tax of \$100 on every girl who left Canada.

"She's worth more," the doctor remarked, while the club hilariously assented. She was

worth \$1,000 to the country, and it would pay to give her family that to keep her at home.

In the States, those who went over were taken in and well treated. Never was it asked where did a man come from, but what could he do? He was impressed with the extraordinary kindness of the feeling there. They were not treated as foreigners, and after twenty years he could say that not once had the question come up.

They might take a lesson from that, for he had noticed a carping spirit in Canada against Americans. It ill became them to speak in any way derogatory of those among whom a million of their own lived as brethren. He would urge all Canadians, when they thought of the war of the revolution, to think how much that war had done for the mother country and for Canada, when it brought over the picked blood of the United Empire Loyalists. When they thought of the Fenian raid they should think of the silent raid going on ever since from Canada, and keep their mouths as with a bridle. When they thought of the Alabama claims, they should think of the thousands and thousands of dollars brought over every summer by Americans to Canada. When they thought of the Alaskan boundary, they should think of the trek to the south of their own citizens. He hoped they would live closely and comfortably, in harmony.

British relationship was a very delicate problem. A great many miles separated them, and the tie was, after all, only a tie of sentiment. He said only, but there was no stronger tie. Sentiment ruled them in every relation of life. It sent their young men to battle in South Africa, and what stronger was needed? Great care was needed by the politicians of the old country and of this to promote a proper and organic unity. Only three courses lay before them, annexation, independence, or some measure of imperial federation. Great nonsense had been talked about the difficulties connected with federation, but he could see no remarkable difficulties in contrast with the advantages. The chief difficulty was that Britain beyond the seas wanted everything and would give nothing to the mother land in return. They had to take a share in the responsibilities and could not ask the mother country to be constantly providing for her children.

What were the ideals they should cherish for their own country? He was glad to speak to them as men. Men under forty cherish ideals. After forty they were not so easy to cherish. It was sane and reasonable to think of themselves as a strong race, and they were satisfactorily situated for the development of one strong in body. Rarely had a strong nation appeared elsewhere than in the north. The cold and rigor of the winter was much to their advantage, and would produce a stronger type than any other on the continent. In their generation, by far the most virile nation would dwell north of the Great Lakes. The amalgamation and commingling of the heterogeneous elements of English, Irish, and Scotch was the best mixture the world had seen. He would get it arranged by Act of Parliament that every fourth Upper Canadian should marry

a French Canadian girl, and the future of the race would be assured.

They wanted a strong race mentally. It was easy to grow corn and potatoes, but they could not grow brains.

"Brains come hard and come high." But they could foster elementary education by well equipped schools and teachers. No problem was more important than that of getting good masters, for it was not good for the boys to be brought up under women. They must pay better salaries, and make their teachers feel they were doing useful and honorable work for their country, with a prospect of a provision for old age and family. The university problem was rapidly approaching solution, and the rapidity with which the provincial university was growing made him hope it would get to the breast of the province and not be bottle fed as it has been so long.

Canadian literature, as represented in the magazines and journals, was advancing, and in one line particularly, not much thought of by business men, Canada reached a high level. Poetry was a very important matter, and they should not look disparagingly upon it. Where there is no vision the people perish, had been said of old, and the vision came not so much to the people as by the poets. He would advise them when they had a young fellow scribbling verses in the office to raise his salary.

The most important thing was to grow a strong race morally, and it was the hardest of all. He did not think Canada immoral. Homicides were less frequent, and drunkenness not so prevalent, though some of them with Scotch fathers might have a little tissue thirst. Illegitimacy was rare, and divorce rarer perhaps than they would like it to be. Morally the country had made a good start, but there was far too much evil speaking, lying, and slandering in connection with political life. It was entirely superfluous and unnecessary. Young men in this atmosphere of slander and hostility towards opponents suffered great harm. He regarded it as an infinitely worse vice than drunkenness. The only way to meet it was simple indeed.

They should deal with political opponents in an everyday Christian spirit, or if not in the character of St. Paul's noble Christian, at least in that of Aristotle's true gentleman. The young were taught to distrust by this mud slinging, and that very easily passed from the sphere of politics to distrust of one's neighbor, and to a general lack of human sympathy and brotherhood, which they should have to one another as Canadians.

Heredity; Its Influence for Good or Evil.—Barr, in the *Alienist and Neurologist*, for November, 1904, refers to the common assertion that heredity is law, which law is verified by accumulated evidence gathered in every department of science that treats of organic life. The law of physiological heredity is based upon the tendency observed in every organism to repeat itself in its descendants. In the higher animals this includes the transmission of psychic qualities, which depend upon physiological conditions. Haeckel observes that heredity is a kind of growth, like the

spontaneous division of a unicellular plant of the simplest organization.

There are many variations in heredity, but the author wishes to consider only three broad divisions, the direct, the reversional, and the collateral. In direct heredity the offspring may receive physical and psychical characteristics from both parents in equal degree, or there may be resemblance to one more than to the other. Again there may be a difference according to sex, the son receiving paternal, the daughter maternal characteristics, or the reverse. In reversional heredity, or atavism, we have a form which attests the certainty of hereditary transmission. The offspring may resemble neither parent, but may develop physical traits or other qualities which are traceable to a grandparent or some more remote progenitor.

In the reversion to type which occurs in this phase of heredity, the prepotency of type frequently asserts itself, either in hastening degeneracy or in an effort of nature to redeem the race. Thus in a family contaminated with various defects on account of repeated neurotic intermarriages, the admixture of uncontaminated stock resulted in normal children, though the taint reappeared in later generations.

In indirect or collateral heredity we have the appearance of qualities which were not prominent in immediate, but in collateral progenitors, uncles or aunts more or less remote. This is an evidence only of atavism traceable to neuroses in a common ancestor, which are tenacious and are revealed in many descendants rather than in one. In "use heredity" we have a similar persistence, the repetition of habit or occupation becoming a feature of the family or nation and being transmitted. In the same way certain powers or even organs are lost because the animal or the individual is no longer dependent upon them.

The law of cinetogenesis, or of use and disuse, as stated in 1809 by Lamarck, is that "the development of organs and their force or power of action are in direct relation to the employment of these organs." In view of the mystery of life and the responsibility of race continuity the author expresses the conviction that no man or woman with a pronounced heredity of ill, physical or psychical, has a right to risk its transmission. The surest rescue of a race from imbecile childishness is a prolongation of normal childhood, full of healthful exercise and free from mental precocity, which delays the period of puberty. If marriage is deferred until maturity in full vigor is attained, the period of reproduction will be proportionally advanced, and the quality of the race will be preserved without diminution of numbers.

To Aid the Metropolitan Hospital and Dispensary.—To increase the fund being raised by the members of the Ladies' Auxiliary for the Metropolitan Hospital and Dispensary, a point euchre and dance is to be given at the St. Regis on Tuesday evening, February 28th. Dancing is to begin at ten o'clock, the card games preceding to

start at half past eight o'clock. Tickets may be obtained either from the president, Mrs. Birnbohm, of Buckingham Court, Ninety-ninth Street and Riverside Drive, or Mrs. J. Alexander Brown, of 1556 Broadway.

Official News.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the period from February 11 to February 17, 1905:

Smallpox—United States.

Place.	Date.	Cases.	Deaths.
California—San Francisco.	Jan. 21-28.	1	
Illinois—Chicago.	Feb. 4-11.	26	2
Illinois—Galesburg.	Feb. 4-11.	1	
Kentucky—Louisville.	Feb. 2-9.	2	
Louisiana—New Orleans.	Feb. 4-11.	8	
Michigan—Detroit.	Feb. 4-11.	4	Imported.
Missouri—St. Louis.	Feb. 4-11.	41	2
New York—New York.	Feb. 4-11.	3	1
Ohio—Dayton.	Feb. 4-11.	1	
Pennsylvania—Allentown.	Feb. 4-11.	1	Imported from Portage.
Pennsylvania—Lancaster.	Jan. 28-Feb. 4.	1	
Tennessee—Memphis.	Feb. 4-11.	3	
Tennessee—Nashville.	Feb. 4-11.	2	

Smallpox—Foreign.

Argentina—Buenos Aires.	Nov. 1-30.	15	18
China—Shanghai.	Dec. 24-Jan. 7.	15 cases foreigners, 130 deaths natives.	
Ecuador—Guayaquil.	Jan. 18-25.	17	4
France—Paris.	Jan. 21-28.	17	
Germany—Bremen.	Jan. 14-21.	4	
Great Britain—Hull.	Jan. 21-28.	7	
Great Britain—Leeds.	Jan. 28-Feb. 4.	20	1
Gt. Britain—Newcastle-on-Tyne.	Jan. 1-28.	7	1
Great Britain—South Shields.	Jan. 21-28.	2	
India—Bombay.	Jan. 10-17.	1	62
India—Calcutta.	Jan. 7-14.	1	2
India—Karachi.	Jan. 15-22.	1	
India—Madras.	Dec. 31-Jan. 13.	1	
Italy—Lecce Province.	Jan. 12-26.	95	4
Italy—Palermo.	Jan. 1-28.	31	5
Norway—Christiania.	Jan. 21-28.	2	
Russia—Warsaw.	Dec. 3-10.	2	4
Turkey—Constantinople.	Jan. 22-29.	1	9

Yellow Fever.

Ecuador—Guayaquil.	Jan. 18-25.	3	
Mexico—Coahuacalcos.	Jan. 28-Feb. 4.	1	
Mexico—Juichitan.	Jan. 29-Feb. 4.	2	
Panama—Colon.	Jan. 23-29.	1	1
Panama—Panama.	Jan. 1-28.	13	4

Cholera.

India—Calcutta.	Jan. 7-14.	106	
Russia—Don territory.	Dec. 31.	2	
Russia—Government of Astrakhan.	Nov. 14-21.	3	
Russia—Government of Astrakhan.	Dec. 21-27.	1	
Russia—Government of Baku.	Nov. 14-21.	168	5
Russia—Government of Baku.	Dec. 14-21.	273	
Russia—Government of Erivan.	Nov. 14-21.	324	279
Russia—Government of Samara.	Dec. 21-27.	1	
Russia—Government of Saratow.	Nov. 14-21.	11	
Russia—Government of Saratow.	Dec. 21-27.	8	3
Russia—Trans-Caspian Territory.	Nov. 14-21.	37	
Russia—Trans-Caspian Territory.	Dec. 21-24.	3	
Russia—Volga Province.	Nov. 14-21.	69

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending February 15, 1905:

EARLE, B. H., Assistant Surgeon. Granted leave of absence for seven days. February 13, 1905.

FOWLER, J. B., Acting Assistant Surgeon. Granted leave of absence for thirty days from March 7th.

FRICKS, L. D., Passed Assistant Surgeon. To report to Surgeon G. W. Stoner, Immigration Depot, New York, N. Y., for duty. February 14, 1905.

GASSAWAY, J. M., Surgeon. Bureau letter of February 3, 1905, granting Surgeon Gassaway leave of absence for ten days from February 9th, amended to read ten days from February 14th.

McKAY, MALCOLM, Pharmacist. Upon being relieved at Wilmington, N. C., by Pharmacist S. W. Richardson, to proceed to Boston, Mass., and report to the Medical Officer in Command for duty and assignment to quarters. February 9, 1905.

RICHARDSON, S. W., Pharmacist. Relieved from duty at Boston, Mass., and directed to proceed to Wilmington, N. C., and report to the Medical Officer in Command for duty and assignment to quarters, relieving Pharmacist Malcolm McKay. February 9, 1905.

WERTENBAKER, C. P., Surgeon. Relieved from duty at the Immigration Depot, New York, and directed to proceed to Havana, Cuba, for duty in the office of the United States Consul. February 6, 1905. Granted leave of absence for twenty days from January 22nd.

WICKES, H. W., Passed Assistant Surgeon. Leave of absence for one day granted Passed Assistant Surgeon Wickes by Bureau telegram of January 28th, revoked.

Board Convened.

Board convened to meet at Fortress Monroe, Va., for the purpose of making an investigation as to the cause of the damage to the launch *Spray*. Detail for the board—Surgeon J. B. STONER, chairman. Acting Assistant Surgeon H. W. KEATLEY, recorder. February 9, 1905.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending February 18, 1905:

KENDALL, WILLIAM P., Major and Surgeon. Granted leave of absence for twenty-two days, to take effect February 5, 1905; on expiration of leave, ordered to proceed to Manila, P. I.

STEPHENSON, WILLIAM, Major and Surgeon. Assumed temporary charge of the Chief Surgeon's Office, San Francisco, Cal.

TORNEY, GEORGE H., Lieutenant Colonel and Deputy Surgeon General. Left United States Army General Hospital, Presidio of San Francisco, Cal., on February 4th, on thirty days' leave of absence.

WELLS, GEORGE H., Major and Surgeon. Relieved from duty in the Division of the Philippines and ordered to proceed to San Francisco, Cal., and report for orders.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending February 18, 1905:

BACKUS, J. W., Assistant Surgeon. Ordered to the Naval Hospital, Portsmouth, N. H., and to additional duty on the *Southerly*.

BAGG, C. P., Surgeon. Detached from the Naval Hospital, Mare Island, Cal., and ordered to the Naval Station, Guam, L. I., sailing from San Francisco, Cal., on February 25, 1905.

BOGAN, F. M., Passed Assistant Surgeon. Detached from the *Decatur* and ordered to the Naval Hospital, Yokohama, Japan, for treatment.

DUNN, H. A., Assistant Surgeon. Detached from the Naval Hospital, New York, N. Y., on February 20, 1905, and granted leave for six weeks.

MUNSON, F. M., Surgeon. Detached from the Naval Station, Olongapo, P. I., and ordered to the Naval Station, Guam, L. I.

WILLIAMS, H. B., Passed Assistant Surgeon. Detached from the Naval Hospital, Norfolk, Va., on February 14, 1905, and ordered to the *West Virginia*.

Births, Marriages and Deaths.

Married.

FAHNSTOCK—PERRY.—In New York, on Wednesday, February 15th, Dr. Ernest Fahnstock and Mrs. G. de Grove Perry.

HOLLAND—DE MITKIEWITZ.—In Cambridge, Maryland, on Wednesday, February 15th, Dr. Arthur Lawrence Holland and Countess de Mitkiewitz.

JOHNSON—SATTERLEE.—In New York, on Tuesday, February 14th, Mr. Tracy A. Johnson and Miss Laura Satterlee, daughter of Dr. and Mrs. F. Le Roy Satterlee.

Died.

ANDERSON.—In Traverse City, Michigan, on Wednesday, February 8th, Dr. Humphrey B. Anderson, in the forty-seventh year of his age.

ARNOLD.—In Omaha, Nebraska, on Friday, February 3rd, Dr. Edward Dudley Arnold, in the fifty-eighth year of his age.

BULLITT.—In San Antonio, Texas, on Thursday, February 12th, Dr. Cuthbert Bullitt, in the eighty-fourth year of his age.

BUTLER.—In Sparta, Virginia, on Thursday, February 9th, Dr. John D. Butler, in the eighty-sixth year of his age.

CARROLL.—In Niobe, N. Y., on Wednesday, February 8th, Dr. Ava M. Carroll, in the forty-eighth year of her age.

COWAN.—In Greensburg, Pennsylvania, on Sunday, February 12th, Dr. Frank Cowan, in the sixty-first year of his age.

DE LANNY.—In Telluride, Colorado, on Monday, February 6th, Dr. C. W. de Lanny, in the fifty-first year of his age.

DELKER.—In Philadelphia, on Tuesday, February 14th, Dr. Frederick Delker.

DE NEVERS.—In Chicago, Illinois, on Thursday, February 9th, Mrs. Ethel May de Nevers, wife of Dr. Francis de Nevers.

FORD.—In Detroit, Michigan, on Wednesday, February 8th, Mrs. M. J. Ford, wife of Dr. Charles E. Ford.

GITTINGS.—In Philadelphia, on Thursday, February 9th, Dr. J. B. Howard Gittings, in the sixty-eighth year of his age.

GREENFIELD.—In Greenville, Mississippi, on Wednesday, February 8th, Dr. Cyrus Greenfield, in the seventy-sixth year of his age.

HAGADORN.—In Bay City, Michigan, on Tuesday, February 7th, Dr. A. F. Hagadorn, in the fifty-fourth year of his age.

HEATH.—In Scranton, Pennsylvania, on Tuesday, February 7th, Dr. William H. Heath, in the eighty-sixth year of his age.

JOHNSON.—In Sag Harbor, Long Island, on Monday, February 13th, Dr. Peter Roosevelt Johnson, in the seventy-eighth year of his age.

LESLIE.—In Cincinnati, Ohio, on Wednesday, February 8th, Dr. James Leslie.

MILAN.—In Paducah, Kentucky, on Thursday, February 9th, Dr. M. G. Milan, in the seventy-fourth year of his age.

MITCHELL.—In Mangoluck, Virginia, on Wednesday, February 1st, Dr. William Alpheus Mitchell, in the sixty-first year of his age.

PADULA.—In Quincy, Massachusetts, on Thursday, February 9th, Dr. Thomas F. Padula, in the forty-sixth year of his age.

PRESTON.—In Dansville, N. Y., on Saturday, February 4th, Dr. Wooster Beach Preston.

RAMSAY.—In Kensington, Pennsylvania, on Monday, February 13th, Dr. Alexander Ramsay, in the fifty-fifth year of his age.

SCHMIDT.—In St. Louis, Missouri, on Thursday, February 9th, Dr. John Schmidt, in the thirtieth year of his age.

SHAPLEIGH.—In Shanghai, China, on Friday, February 3rd, Dr. Alfred L. Shapleigh, in the thirty-sixth year of his age.

SHERWOOD.—In Washington, D. C., on Wednesday, February 8th, Dr. Thomas Humphrey Sherwood, in the seventy-second year of his age.

TUXBURY.—In Denver, Colorado, on Sunday, February 5th, Dr. Fred P. Tuxbury, in the thirty-eighth year of his age.

THE SURGICAL TREATMENT OF HÆMORRHOIDS.*

By CHARLES MCBURNEY, M. D.,

NEW YORK.

During the last decade the actual or possible application of surgery to every organ and region of the human body has been usually most carefully studied, and, as a rule, scientific methods of a high degree of perfection have in each instance been developed, the completeness of the operative procedures, and the careful attention to detail, both during the operations and throughout the after-treatment, leaving little or nothing to be desired. In the case of hæmorrhoids it has seemed to me that surgeons have failed to devote the same careful attention that they have given to other subjects; that they have been willing to continue to make use of crude and often imperfect methods, and that they have not given operations on hæmorrhoids the full benefit of their knowledge of asepsis, and of detail in after-treatment. It is a fact certainly that a large number of individuals are still subjected to operations too crude and too severe in character, that the convalescence thereafter is often painful and too prolonged, that the wounds often suppurate, and that disabilities, the result of operation, are not infrequent. In these defects in the surgical treatment of hæmorrhoids is to be found the chief reason why an unduly large number of persons who suffer from hæmorrhoids, either avoid operation entirely, or apply to the quack, who offers a treatment which, while far from perfect, is comparatively free from pain and discomfort and brief in duration. A recent perusal, which, I must confess, was by no means a complete one, of literature referring to hæmorrhoids, only confirms my belief that the surgical treatment of these tumors, as frequently practised, can be much improved. In this connection I will quote from the article on hæmorrhoids in a very recent

(1904) and an important publication, which covers the whole range of general surgery:

"A patient who is to be operated on for hæmorrhoids should take castor oil for two days in order to thoroughly empty the bowels. He is then placed under a local or general anæsthetic and put in the lithotomy position, while the parts are thoroughly cleaned. The sphincter is gradually dilated until the hæmorrhoids are exposed. The individual nodules are seized with a special forceps so applied that the pinch of the mucous membrane shall extend longitudinally and not transversely. As a further precaution against stenosis there should be considerable mucous membrane left between the portions to be excised. A second clamp is applied to the pedicle of the hæmorrhoid, and the hæmorrhoid is divided between these two clamps by means of the point of the cautery. If the hæmorrhoid is a large one it may be cut off with scissors in order to save time, and its stem cauterized. If the cautery is not too hot, and it is thoroughly applied, there will be no bleeding upon the removal of the second clamp. If an artery spurts it should be ligated. Dilated veins that are not large enough to be removed in this manner may be punctured with the point of the cautery. When all the hæmorrhoids have been treated in one of these ways, a thin tube wrapped with iodoform gauze is passed through the sphincter to allow the escape of gas; the anus is smeared with vaseline and a dressing of gauze and cotton applied and held in position by a T bandage. Some patients have no pain after such an operation, while others suffer so much as to require morphine injections. It is unnecessary to give opium in order to delay defæcation. On the third or fourth day castor oil and an enema should be given to facilitate defæcation, but even then the process is painful. Some surgeons prefer to give a laxative on the day after operation. Defæcation is then less painful, but may be followed by some rise in temperature. Either during defæcation, or immediately afterward, the patient should sit in a warm bath for the sake of his comfort and clean-

* Read at a meeting of the Practitioners' Society of New York.

liness. After the fourth day the bowels should act daily. The patient may get up in a week, though a perfect cure requires from three to six weeks. If the operation has been properly carried out there is no necessity to pass rectal bougies in order to prevent cicatricial contraction. For the purpose of cutting off the hæmorrhoid one may use the tip of the galvanocautery instead of the thermocautery."

The operation as thus described certainly seems rather formidable and unattractive. I might make numerous quotations from other authorities in support of my statement that operations on hæmorrhoids, as frequently practised, are open to improvement. Hæmorrhoids are vascular tumors, composed chiefly of enlarged veins with a few arteries. When entirely or largely external these tumors contain also a variable amount of new tissue and inflammatory exudate. When entirely internal the elements last referred to are nearly or completely absent. It is not my intention in this brief communication to discuss at length the causes of the production of these tumors. A congenital tendency to venous enlargement such as is seen in the legs, thighs, and scrotum, exists in many individuals in the hæmorrhoidal veins, and in addition we recognize the causative influence of a constantly loaded rectum, very continuous maintenance of the sitting posture, a sluggish venous circulation which accompanies overeating and drinking, and imperfect liver action, and absence of a normal amount of exercise to promote normal circulation. More immediate interferences with the return of venous blood from the lower rectum and anus are carcinomata and other tumors, malpositions of the uterus, pregnancy, enlargement of the prostate, and an irritable contracted sphincter muscle, or an enfeebled flabby condition of the levator ani muscles. Many of these causes are removable, and, at least, efforts should be made to remove the cause before resorting to operation for the cures of hæmorrhoids.

Very painful external hæmorrhoids are frequently produced, or suddenly aggravated by an irritable, firmly contracted sphincter muscle, which effectually prevents the return of blood from the anus. In these cases dilatation of the sphincter will often effect a satisfactory cure without other operation. By dilatation of the sphincter I mean such a stretching of the muscle, properly accomplished while the patient is under the influence of an anæsthetic, that the unnatural contractions of the muscle are entirely overcome. The result of this operation in similar cases is that the constriction of the vessels being

removed, the tumors below the constriction at once empty themselves of blood, and become so rapidly reduced in size that often, on the following day, little or no evidence of hæmorrhoids will be found.

Dilatation of the sphincter is an operation deserving of some care and delicacy of manipulation. The fingers are by far the best instruments. Mechanical appliances are much more liable to tear mucous membrane and do real injury to the muscle. The rectum having been emptied by an enema, and the parts having been thoroughly cleansed, the patient should be anæsthetized and placed on the side with the knees drawn up. One forefinger, well lubricated with some sterile material, is gently passed through the sphincter. Then two fingers are passed together, and then three fingers. Relaxation of the sphincter will be already noted.

The two forefingers are then to be introduced back to back and flexed so as to form two hooks in the concavity of which the muscle rests. By traction gently applied first from side to side, and then anteroposteriorly, the muscle is made to yield without rupturing the mucous membrane. After a few moments the muscle becomes quite unresisting, the anus is widely dilated and no injury has been done. If too great violence is used, or if the dilatation is made too rapidly, numerous fissures will be produced which may or may not heal. To obtain the full benefit of this operation the anus and other parts involved must be firmly supported and put at rest by means of a large conical pad made of loose gauze, the apex of the cone supporting the anus and the base resting upon a good wide firmly applied T bandage. The bandage and pad need not be worn more than twenty-four hours, and on the second day a mild laxative should be given. The cases to which this operation is applicable are those in which a firmly contracted sphincter muscle produces an acutely distended condition of the hæmorrhoidal tissue which is situated below the sphincter. Such cases may be complicated by more or less extensive internal hæmorrhoids. Even then stretching the sphincter will give immediate relief to the acute symptoms.

The internal hæmorrhoids will, of course, remain, and will require for their cure an operation of a different character. Another acute condition which occurs in connection with external hæmorrhoids is produced by the rupture of a vein within the hæmorrhoid. This rupture may occur as a result of an effort at defæcation or there may be no assignable cause. The extravasated blood distends the hæmorrhoid, œdema rapidly

occurs, the return of venous blood is prevented and severe pain is felt. Here, also, the sphincter responds to the irritation, contracts forcibly and still further impairs the circulation. In these cases the extravasated blood usually rapidly coagulates, forming a clearly defined, round, subcutaneous tumor, the dark color of which is often discernible through its thin covering. Relief can be easily given by removing the coagulum. This is readily and painlessly done, after injecting a few drops of a two per cent. cocaine solution, by making a small incision directly down to the coagulum, and turning it out of its bed. Firm pressure should be maintained for a few minutes until all oozing has ceased. The small wound will heal rapidly if especial care in regard to cleanliness is taken for a few days. The very large majority of hæmorrhoids are of a more or less chronic character before the attention of either patient or physician has been called to them.

Various well known symptoms arise, such as pain, hæmorrhage, etc., and relief is sought. It is noticeable, however, that many individuals with hæmorrhoids have no symptoms of the disease, and suffer no annoyance whatever. Such cases require no operative interference unless the condition is such that increasing size, and the development of the usual symptoms, are clearly to be apprehended. The fact that distinct hæmorrhoids and a very marked superabundance of mucous membrane often cause no symptoms, clearly suggests that it is not necessary to do extensive operations in order to produce entirely satisfactory cures.

It having been decided that palliative measures are not sufficient for a given case, and that a radical cure is clearly desirable, the question in regard to the methods to be employed is to be answered.

The methods to which I wish especially to refer are, first, the method by injection; second, operation with clamp and cautery, or with cautery alone; third, the operation known as Whitehead's; fourth, the operation which I shall describe in detail, and which seems to me to possess decided advantages over the others. It is sufficient to say of the injection method that it is not constantly radical, and that it not infrequently results in suppuration or sloughing. I think it rests with those who advocate the use of the cautery in operating upon hæmorrhoids to show that this method has distinct advantages which outweigh its disadvantages. In operating upon other parts of the body surgeons do not usually select the cautery and the eschar which it produces, as preferable to the knife, suture, and

primary union. My own belief is that the problem of the removal of hæmorrhoidal tumors differs in no essential particular from the problem of the removal of superficial tumors elsewhere, and that, when proper care is exercised, perfectly clean aseptic healing can be secured when operating through mucous membrane. So far as the vascular nature of hæmorrhoidal tumors is concerned, the cautery has no advantages, as is shown by the general agreement among modern surgeons that such tumors as nævoid growths of great vascularity are usually best treated by complete extirpation with the knife. Occasionally, for the treatment of one or two single dilated hæmorrhoidal veins, or very small vascular nodules, or in cases where hæmorrhoids are already in a sloughing condition, the cautery is convenient. The operation known as Whitehead's consists in a resection throughout the entire circumference of the anus of hæmorrhoids, mucous membrane, and submucous tissue. The dissection of the lower end of the rectum is carried as high as the hæmorrhoids extend and the tissue is there divided circularly throughout the circumference of the intestine. The edge of the divided mucous membrane above, and the mucocutaneous edge below are then drawn together and sutured. The suture line is necessarily imperfect, and an annular cicatrix is produced just at or above the anus. This operation is usually applied to such cases as present numerous hæmorrhoids, and it is claimed that, by it, the whole "pile bearing area" is removed. The operation seems to be based upon the theory that all vascular tissue and all mucocutaneous folds are abnormal and that cure can only be accomplished by the complete extirpation of these tissues. This theory is not supported by observation, for even in those healthy individuals who have no symptoms of hæmorrhoids, vascular tissue and mucocutaneous folds are often abundant. In cases where at a superficial examination the anus seems to be filled and surrounded by hæmorrhoids, a more careful examination will result in the identification of two or three hæmorrhoids which really give rise to the symptoms and the removal of which, by a much less severe operation, will produce an entirely satisfactory condition. In the occasional case where the removal of two, or at most three hæmorrhoids does not seem to be sufficient, it is better, nevertheless, to be satisfied, for the time being, with an operation of that extent. After complete healing has occurred one will be surprised to find often that little or nothing more remains to be done. If, however, one or more distinct hæmorrhoids require treatment, they

may again be operated upon in a simple manner. Whitehead's operation has far too frequently resulted in prolonged ulceration, and in most intractable stricture, to be recommended under any circumstances.

The operation to which I especially wish to call attention as the one which I much prefer to all others, originated in the operation known as Allingham's. I have performed it in a large number of cases for many years, making an occasional improvement from time to time, until now I feel justified in recommending it to others. The success of this operation depends, as is the case in most surgical work, upon a careful attention to detail, the description of which will, I hope, not prove too wearisome.

The careful examination of the patient before the time set for operation is important, for before an anæsthetic is given it is usually possible to accurately determine the exact situation and size of the tumor or tumors which require removal. After the anæsthetic is given, and particularly after the sphincter has been stretched and the rectum irrigated, the extrusion of relaxed mucous membrane is often so great that one is in doubt what to remove and what to leave. Neglect to make a careful preliminary examination not infrequently leads, I think, to the doing of a much more extensive operation than is required.

On the night before operation a half ounce of castor oil should be given, or, if that is especially objectionable to the patient, other good laxatives will do as well. Purgation is by no means desirable, and is likely to lead to loose defæcations during the operation. A large soap application should be made to the perinæum and adjacent parts, to be worn for at least six hours before operation. Shaving of the neighborhood of the anus is not necessary and is disagreeable. At least two hours before operation the rectum and lower intestine should be washed by an ordinary enema. Sufficient time will then be left to allow all fluid to drain away. The vagina should also be irrigated and then packed tightly with sterile gauze. The operation can be best done with the patient in the lithotomy position, the buttocks being drawn down so as to overhang the edge of the table, the surgeon being seated in front of the parts to be operated on. Examination of the rectum should now again be made, so as to identify the exact limits of the tissue which requires removal. The sphincter is to be gently but thoroughly stretched, not only to facilitate the operative work, but also that there may be no spasmodic action of the muscle afterwards, which would be certain to cause pain and would prob-

ably interfere with perfect wound healing. With the aid of a large glass speculum, which I prefer, or a Sims's speculum, the rectum should be thoroughly irrigated with warm salt solution and then dried. If the anus is held wide open during this irrigation, fluid will not pass up the intestine, and subsequently annoy the operator by descending at intervals. The perinæum and buttocks are to be washed with ether and the surrounding objects excluded with sterile towels with as much care as would be exercised if one were about to do a laparotomy. If the surgeon wears operating gloves—who does not to-day?—now is the time to put them on. If one is sufficiently attentive to the requirements of aseptic detail when operating upon the rectum the most perfect wound healing can be obtained.

The hæmorrhoid to be operated upon is grasped with a tight clamp from side to side, lifted gently from its attached aspect by an assistant, while the operator with a knife (not with scissors) makes an incision on either side of the tumor, parallel with its long axis, through the mucous membrane above, and the skin below. The two incisions should meet at a very acute angle below, and should invade the skin only enough to make this angle and avoid producing an awkward fold or tag. The tumor with the surface included by the incisions is now to be dissected up with the knife or with straight, sharp scissors. This dissection must include the vessels of the hæmorrhoid, but no more surrounding tissue than is necessary. The incisions can now be continued upward on either side, always converging to a point just above the hæmorrhoid. They need not actually meet. As the tumor is now still further dissected upwards, and as the incisions and plane of dissection converge towards the same point above, the remaining attachment of the tumor is reduced to a small pedicle which, if care has been exercised, will be found to contain the principal artery of supply and emergent veins. At the highest part of this pedicle a catgut ligature is to be tightly tied about it. The hæmorrhoid is not yet to be cut away. The long, narrow wound is to be carefully searched, and every bleeding vessel tied or twisted. Often no ligatures are required: sometimes four or five. No bleeding is to be neglected. The wound must now be very neatly sutured with a continuous suture of No. 1 catgut, beginning at the lower angle. A tenaculum which pulls down the lower angle is of assistance in making the wound edges approximate evenly, and, as one approaches the upper part of the wound, traction upon the hæmorrhoid brings the whole wound

into view. Sometimes a flat retractor on the opposite side of the anus is needed. The suture is to be continued until the very base of the pedicle is reached and then tied. Now the hæmorrhoid may be cut away just below, but not too near the ligature on the pedicle. If a second or third hæmorrhoid exists it is to be removed in the same manner, care being taken not to cut into one wound while making the other. As a rule, not more than two good sized hæmorrhoids can be removed at one sitting without taking away an undue amount of mucous membrane. When there appears to be the slightest danger of taking away too much tissue, it is much better to postpone further operation until the patient has completely recovered from what has been already done. When the time comes to make a second thorough examination one will usually be surprised to find a complete absence of the tissue upon which a second operation was planned. Blood or other soiling is finally to be washed away with salt solution and the parts dried. Now introduce a suppository containing one grain of opium, or $\frac{1}{8}$ grain of morphine. The dressing is very important if œdema of the lower angle of the wounds, pain, and delay in healing are to be avoided.

First adjust perfectly the abdominal portion of the T bandage. No ordinary T bandage will be of service. For these cases, and indeed for almost all cases, the abdominal portion must be about twelve inches wide or more, such as would be used after a laparotomy. The perineal part of the bandage must be eight inches wide behind, narrowing slightly as it passes the perinæum, and then be wider or not as desired. The material of the bandage should be good, heavy Canton flannel. With such a bandage as I describe, real support can be given through the dressing to the parts operated upon. Loose sterilized gauze is now to be packed against the anus, fold on fold and in quantity, until the whole ischio-rectal fossa is more than full. Abundant squares of gauze are to be laid on this packing, and then a good thick layer of cotton. The perineal band is now to be put in place and drawn very tightly, the object being to push the anus and lower rectum forcibly into the pelvis, thus completely immobilizing the parts and taking all weight off of the levator muscles. This complete immobilization is most important, both to secure immunity from pain and primary union of the wounds.

No food of any kind is to be given until the following day. Sufficient water may be given to entirely allay thirst. One sixth of a grain of morphine immediately after operation will not be

too much. After the day of operation $\frac{1}{4}$ grain of extract of opium is given every eight hours, so that defæcation may not occur until the sixth or seventh day. For the same reason only very small meals are given, and those should be of a varied character. Milk and broths load the intestines, produce bulky and often hard movements, and induce the desire to defæcate. The dietary should be about as follows: Breakfast, a small cup of tea or coffee, one egg, and a piece of toast. Luncheon, one chop and a piece of bread, with butter. Dinner, a small quantity of chicken or beef and one vegetable, with bread. Water frequently in small quantities at a time. This limited diet I have found entirely satisfactory, as the patient appreciates that defæcation is not desirable, and the opium taken diminishes appetite. Patients treated in this manner are entirely free from pain and remain perfectly comfortable day after day. After three days it is usually sufficient to give the opium twice daily and after four days once a day. Gas in the lower intestine gives rise to no difficulty, for it soon finds its way out in spite of the tight dressing. Tubing introduced as part of the dressing is entirely unnecessary. Of course, some patients require the use of the catheter, and in females I order it so that no soiling may occur. Male patients may be allowed to stand up after the second day to urinate and thus often avoid the catheter. On the second day after operation the dressing is changed, and the anus and adjacent skin gently washed with a weak solution of peroxide of hydrogen. The anus will be found deeply depressed, entirely free from pain, and without œdema. By the end of three days after operation a slightly looser dressing may be permitted. On the sixth day, sometimes not until the seventh day, a half ounce of castor oil, or a drachm of compound licorice powder is given at about 10 a. m., as it is desirable to have the bowels act during the daytime, when the patient can be conveniently attended to, and the night is thus left undisturbed. When urgent desire to empty the bowels is felt, the patient should get up out of bed and be seated upon a comfortable commode or water closet seat, and he should not be subjected to the discomfort and straining which are so usual when the bed pan is used. The sitting posture is much more favorable, and if no effort at straining is made, the movement will take place entirely painlessly and without bleeding. After the movement the anus should be gently washed externally. If a second movement occurs $\frac{1}{4}$ grain of opium should be given to prevent further disturbance of the parts operated upon. Two days later any good

laxative will do, and daily evacuation should thereafter be encouraged.

It is claimed for this operation that it is absolutely safe: that it is radical; that neither ulceration or stenosis ever result from it; that convalescence is painless; and that cure is obtained with a minimum loss of time.

28 WEST THIRTY-SEVENTH STREET.

HIGH FREQUENCY, HIGH POTENTIAL CURRENTS, AND X RADIATIONS IN THE TREATMENT OF EPILEPSY.

By SAMUEL G. TRACY, B. Sc., M. D.,

NEW YORK.

There are 12,500 epileptics in New York State. Their number is so large that their treatment and their social condition present a problem which demands the serious consideration of physicians and sociologists. Of the total number of epileptics, 2,500 are public charges in our hospitals, asylums, and special colonies. This still leaves a goodly number who remain in their own homes, and while many of them are apparently in good condition physically, they are compelled to abandon remunerative employment on account of their liability to convulsive fits.

Under the usual methods of treatment comparatively little hope is offered to the unfortunate epileptic. If there has been established the epileptic habit of several years' duration, the cures, by the hitherto most approved methods, are generally considered to amount to not more than 8 per cent.

The object of this paper is to describe a method of treating epilepsy which has given me better results than any treatment I have heretofore used. If the medical profession can be convinced that by the use of high frequency, high potential currents, combined with x radiations, we have comparatively new agencies which will markedly improve, and in a certain percentage of cases even cure, many of the forms of epilepsy heretofore considered incurable, it certainly behooves them as conscientious physicians to give such a system a fair trial. When I speak of comparatively new therapeutical agencies, I am not unmindful of the work done in x radiations by Branth and Grad. In the use of electrical and radiant energy in the treatment of epilepsy, I do not mean that we should limit ourselves to these modalities exclusively, but that we should also utilize such of the older remedies as experience has taught us to be of service; one of these latter, namely the bromides, is indispensable in certain cases. But by the application of the elec-

trical and radiant treatment we can use less of them; in fact, in some cases do without them entirely.

In considering the treatment we should first give attention to the immediate attack, and then, if possible, treat the morbid conditions which produce the seizures. Spratling declares that, in the majority of cases, the cause of epilepsy can be traced either, 1, to malassimilation, combined with dyspepsia; 2, to a disarrangement of some portion of the body, such as the remains of an old neuritis, the scar of a gastric ulcer, an obstetric injury, etc.; 3, to too great mental activity, such as fright in childhood, overwork, or disappointment in love or ambition in youth, physical overwork, insufficient food, lack of variety in work or diversion, in those of mature years; 4, to heredity.

When the disease is due to alcoholism or fright, it is reasonable to suppose a cure may be effected by removing the cause. When an epileptic seizure is preceded by a cramp in an upper or a lower extremity, we can frequently abort the attack by pressing upon, and constricting, the part above the cramp. In other cases the patient can sometimes prevent the attack by concentrating his thoughts upon some other subject. When a convulsion is once established there is but little to do, until it runs its course, except to place the patient on his back, with his head partially bent backward. He should then be moderately restrained, so that his violent movements will not injure him. The clothing should be loosened about the neck and waist, and if in a room, the window should be opened to give a free circulation of fresh air. During the sleeping stage, the head should be bent sideways so that the tongue will not fall back and obstruct the breathing. The sleep after the attack should not be disturbed, and when the patient awakens he should receive nourishment in a concentrated form.

In the treatment of chronic epilepsy we should first look for any exciting or reflex cause and remove it. Among the reflex causes which may be responsible for epileptic seizures are worms, intestinal parasites, or autointoxication. An adherent prepuce, in either sex, producing irritations of the genital organs, foreign bodies in the ears, closure of the Eustachian tube, producing pressure on the internal ear, foreign bodies in the nose, or nasopharyngeal polypi, defects of vision, eye strain, injuries to the scalp or skull, all enter into the ætiology of epilepsy. The removal of such conditions not infrequently alleviates or cures the distressing malady in a remarkable manner.

Nearly all the drugs of the pharmacopœia have

been used at one time or another in the treatment of epilepsy. Since 1851, when Dr. Leacock first used bromides, they have been the sheet anchor of the drug treatment. The bromides produce a marked sedative effect on the nervous and circulatory systems, first by diminishing the excitability of the nerve centres, and then by equalizing the circulation and relieving the congestion.

We now come to the electrotherapeutic treatment of epilepsy. The galvanic and faradaic currents of electricity have been used in former years, but with little success. If Hughlings Jackson's theories regarding the nervous system are correct, it is reasonable to suppose that high frequency, high potential electric currents will have a beneficial effect on the nerve centres, and indirectly on epilepsy. Jackson believes that the nervous system is divided into three "levels" of sensory motor centres, the low, middle, and high. The low level is practically identical with the spinal system. Its centres are mostly automatic. The middle level is made up of the subconscious centres. The highest levels correspond to centres situated in anterior cerebral and occipital regions, the former being supposed to contain the sensory, and the latter the motor centres. It is thought that all parts of the body are represented in this highest level, in centres of great complexity. It is here that the phenomenon of consciousness arises, and while containing the highest sensory and motor centre, this level includes also the centre of intelligence and of the mind generally.

Dr. C. E. Riggs says that epilepsy may be considered a paroxysmal discharging disease of the highest nerve centre level as described by Hughlings Jackson. His theory as to how epilepsy is produced seems so plausible that I quote it here: "The lesions of epilepsy arise from nutritive, molecular disturbances, which may be inherited, or the result of stress of growth and development. They render that part of the nervous system unstable. The nerve centres, which are regarded as accumulators in which nervous energy is stored, instead of giving off their energy in response to due stimulus, liberate it irregularly and explosively. . . . But as the higher centres are also the seat of the 'organ of the mind,' we should expect lesions of these centres also to produce psychological phenomena, and this in fact is exactly what happens in epilepsy proper."

If Riggs's theory is correct, it appears likely that the proper application of high frequency, high potential currents will have a marked nutritional effect on the brain, and thus restore the

motor and sensory nerve centres to their normal function. When high frequency currents are applied to the human body, we find that, owing to the great frequency of the oscillation, even up to several million alternations a second, neither the nerves nor the muscles are excited, but great activity arises in the tissues. This is shown by a greater absorption of oxygen, and an increased production of carbonic acid gas.

The effects on the nervous system are certainly marked. Freund states that subjects of melancholia and hypochondriasis are much benefited by this method of treatment. Other foreign observers have shown that the functional neuroses, such as hysteria and neurasthenia, also respond to these high frequency currents. Personally I agree with the authorities already quoted—but I go a step further to state that decidedly beneficial and curative effects are obtained in epilepsy by the use of high frequency currents, combined with the x radiations. In some cases I used the high frequency current and the x radiation alone, and in others I combined it with the sodium bromide, using from 15 to 60 grains per diem, depending upon the severity of the case. All cases, either of grand or petit mal, were treated in much the same manner. Those of more than three years' standing gave the best results when the high frequency current and the x radiations were combined with small doses of sodium bromide, in females increasing (doubling or trebling) the amount of bromide just before and during the menstrual period.

As a rule, each patient is treated every other day, first receiving x radiation from five to ten minutes from a high tube. This is placed about six to ten inches above the head, so that the rays strike directly upon the anterior and occipital part of the brain (Jackson's centres of high level). After the x radiation the patient is subjected to the influence of a high frequency current, applied over the brain for ten minutes, and for five minutes over the spine. In this manner I have treated the different forms of epilepsy, but I found the best results were obtained by using the combined treatment of x radiation and high frequency currents with small doses of bromides. By this latter method, at least 25 per cent. of petit mal may be considered tentatively cured, 20 per cent. of Jacksonian epilepsy, and 12 per cent. of grand mal. All cases were improved more or less, not only in regard to the frequency of the epileptic seizure, but also in regard to their severity. In addition to this the general, mental, and physical condition was very much improved. As these experiments have

been continued for less than a year, sufficient time has not elapsed to say how much permanent value there is to this method of treatment. Nevertheless, such progress has been made in the cases treated that I believe that we are on the right road to get the best results in the treatment of epilepsy. The cases which I here report are typical of the improvement which can be obtained by the combined treatment, namely, the physical and chemical action of high frequency electric currents and the use in selected cases of sodium bromide, from 15 to 60 grains a day.

CASE VII.—A. G., woman, aged 32 years; began treatment October 10, 1903. Previous history: Twelve years previously, patient had gone in bathing during the menstrual period. This was followed by an excessive menorrhagia, which the patient was not expected to survive. Immediately following the bath, she had had an epileptic seizure, and these attacks had been constant ever since. For the first three years she had a profound convulsion every night. Nine years ago she married, and had had three children (all healthy). The past year the frequency of the fits had been growing less, sometimes twice or three times a week, but lately, and for a few months before she came under my observation, she had had epileptic seizures nearly every night, with occasional attacks of petit mal in daytime. The profound convulsion began with a spasm of the left hand, which gradually moved up to the left ear. The patient usually took hold of the left hand with the right hand, but if both hands were drawn up to the head, then the convulsions began immediately. Her sister said if she was able to grasp the left wrist before the convulsion, she could frequently abort it. Her treatment has been that already outlined, namely, the electricity and x radiations, without bromides.

October 14th, in my office, the patient said a weakness was coming over her, after which she had a slight spasm of the left side of mouth, followed by some mutterings and inability to answer questions. Pupils dilated, skin moist, and great pallor of the face. This attack lasted about three minutes. Upon inquiry I found she had this latter form of seizure two or three times a month, especially if overtired, or if she had had heavy epileptic attacks the night before.

November 14th: Patient has had three treatments a week for six weeks, with the exception of one week, when she was confined to the house with a severe cold. Her mother accompanied her on this visit, and reported that the patient's mentality had improved, she was more sensible and intelligent, her memory was better, and her physical condition improved.

During the past month she had not had a spasm in the left hand, and the epileptic seizures of which she had had from 40 to 60 a month had now been reduced to sixteen. During the month of December she was free from epileptic seizures, except during the menstrual period, and for the past six weeks she had had but one fit—only an occasional cramp in her hand, and no petit mal.

Taking it all in all, she was better physically and mentally, having increased in weight, and improved in memory and general intelligence. She had not been so well or so free from epileptic attacks in eleven years.

CASE XII.—Female, aged 27 years. Grand mal at night, petit mal in daytime. First fit occurred six years previously. The seizure began without marked aura, although patient said there was a slight spasmodic condition of the mouth. For the first three years the profound seizure usually took place at night, and then each successive night for two or three nights. After this she would be free from seizures for three or four weeks. At the end of three years the type of seizure changed; the aura usually began with spasm of the right hand, and wide opening of the eyes. The true convulsion followed, but this always took place at night while she was in bed; but in the daytime she had from ten to twelve attacks of petit mal a month. Treatment: x radiations, high frequency currents, and sodium bromide, fifteen grains, three times a day.

I am inclined to believe that the high frequency currents have some chemical effect on the bromide, possibly liberating a larger quantity of the bromine as the solution of the salt circulates in the brain, and thus the drug in smaller quantities has a more pronounced therapeutical effect in controlling the epileptic seizures.

At any rate, the patients upon whom I have tried it, combined the bromide with the electrical and radiant treatment, respond more quickly than those who have not received the bromide. This last case, after three and one half months' treatment, is very much better, the grand mal seizures are less frequent, and the petit mal attacks rare, usually one during or after the menstrual period.

CONCLUSIONS.

Epilepsy is a serious disease, and in its treatment all reflex irritative disturbances should be first eliminated. In using high frequency, high potential currents, we need not refrain from employing any or all old time remedies which we have found to afford even temporary relief. By the use of high frequency, high potential electric currents, we have a therapeutical agent, which (1) acts as a nerve sedative, (2) controls local congestion, and (3) promotes the normal functional activity of the nerve centres. In addition to this, it is not unlikely, in those patients who take the bromides, that this electric modality sets free a larger amount of bromine in those areas of the brain where the lesion of epilepsy is likely to be located. By this means, possibly in some way as yet unknown to us, it exhibits its remedial influence by controlling the seizures or ameliorating the condition to such an extent that the patient feels warranted in calling himself practically cured.

THE OPEN AIR TREATMENT AT HOME FOR TUBERCULOUS PATIENTS, WITH A DESCRIPTION OF A WINDOW TENT AND A HALF TENT.*

By S. A. KNOPF, M. D.,

NEW YORK,

VISITING PHYSICIAN TO THE RIVERSIDE SANATORIUM OF THE
HEALTH DEPARTMENT OF THE CITY OF NEW YORK; CON-
SULTING PHYSICIAN TO THE SANATORIA AT GABRIELS,
N. Y., SCRANTON, PA., BINGHAMTON, N. Y., ETC.,

AND

W. B. McLAUGHLIN, M. D.,

NEW YORK,

FORMERLY RESIDENT PHYSICIAN OF THE RIVERSIDE
SANATORIUM.

To give the tuberculous patients the greatest amount of pure, fresh air for the greatest possible number of hours in the twenty-four, is the object of modern phthisiotherapy. This constant exposure to the fresh, pure air is, of course, obtainable in the ideal way in the specially constructed sanatorium where the patients recline on comfortable chairs in the open rest cure gallery during the day, and the beds are moved on to the open veranda at night.

To provide the same advantages as far as possible for the large number of consumptives who for various reasons cannot go to a sanatorium, many appliances have been devised. In country homes suitable extensions can often be made with relatively little expense when the patient or his

FIG. 1.—Sleeping shack.

relatives own the house. Again in the country it is often possible, even for the poorer patient now owning a house, to build a so called sleeping shack, which should preferably have southern

* Read before the Medical Society of the County of New York, at a regular meeting.

exposure. It could then serve as a rest cure gallery by day and as an open air sleeping place at night. As the illustration shows, the construction is very simple and not costly. A number of

FIG. 2.—Half tent for the rest cure in the open air.

such shacks are in use even in sanatoria. The photograph represented here (Fig. 1) is of one of the shacks of Dr. Millett's Sanatorium, at Bridgewater, Mass.

In large cities, particularly in the homes of the poor, the flat roof and the fire escape have frequently been used for the purpose of giving the open air treatment during the day. We can hardly recommend the use of the fire escape, as to have it encumbered might endanger the lives of the other inmates in case of fire; but a steamer chair, placed on the roof, will answer the purpose of a costly typical sanatorium reclining chair; a large umbrella will answer the purpose of the protective awning.

For patients in better circumstances, who have a little garden, a yard, or a convenient flat roof, a half tent, such as we show here (Fig. 2), may advantageously replace the rest cure gallery of the sanatorium. This half tent is composed of a

frame of steel tubing, which can be folded together when not in use (Fig. 3). Over this frame strong sail duck is stretched and secured by snap buttons on the inside, so as to completely protect

FIG. 3.—Frame of half tent folded.

the patient against wind and sun. To prevent the tent from being overturned by the wind, the frame has ground spikes holding it securely. The reclining chair is placed in this half tent in such a manner that the floor bracing, attached to the frame, is held down by the chair and thus adds to its security.

The Kny-Scheerer Company have been good enough to construct a reclining chair for me. It is intended for outdoor use, and is made of bent enameled steel tubing, with woven wire springs, top and back (Fig. 4). It has the characteristic knee bend, which should be a feature of all good sanatorium chairs, so as to make the prolonged sojourn of a patient on the chair as restful as possible. The back can be adjusted to any inclination which renders the patient most comfortable. The arm rest can be folded back to make it easy

and convenient for the patient to get into the chair. The tops of the arm rests are of wood, so that the metal will not chill the patient in cold weather, and a mattress is placed over the back as well as over the seat. Half tent and chair should be placed as nearly as possible so that the patient may be exposed to the sun, with his head shaded, and at the same time sheltered from the wind. This chair, being constructed of metal, is somewhat more expensive than the ordinary bamboo chair, but it has the advantage of many times greater durability, not being affected by either extreme heat, cold, or moisture.

Sleeping outdoors in cold weather is perhaps not practised anywhere but in sanatoria, and still it is our conviction that nothing will increase the patient's chances for recovery as much as sleeping at night in a pure, cool atmosphere. An ingenious device for that purpose has recently been described in *Outdoor Life*,¹ under the name of aerarium. It is to be used in connection with Dr. Dunham's bed, which is a cot constructed so that the head of it protrudes through the window. This aerarium is a long, double outside awning so arranged as to keep up a rising current of air without draughts over the head of the patient. From the description it seems that the arrangement is excellent, since it can be applied by a carpenter to any window in a short time.

Those of us familiar with the conditions of the consumptive poor in a large city will, however, agree on the difficulty of making such a device practical and popular among this class of patients. In a New York tenement house, for ex-

FIG. 4.—Reclining chair of steel tubing for the open air rest cure.

ample, the protruding of a cot through the window would attract unpleasant attention, and with the phthisiophobia that exists in many minds, the

¹ *The Outdoor Life*, October, 1904; published at the Adirondack Cottage Sanatorium, Trudeau P. O., N. Y.

unfortunate sufferer might be obliged to seek other quarters. The cost of the aerarium will also bring it beyond the reach of the poor, and since the device is patented, it would be imprudent to endeavor to copy it with a view of producing a cheaper apparatus.

The writers of this article have endeavored, by presenting to the profession the window tent for the open air treatment at home, to overcome the objections indicated.

The window tent is an awning which instead of being placed outside of the window is attached to the inside of the room. It is so constructed that air from the room cannot enter nor mix with the air in the tent. The patient lying on the bed, which is placed parallel with the window, has his head and shoulders resting in the tent (Figs. 5 and 6). By following the description closely it will be seen that the ventilation is as nearly perfect as can be produced with so cheap a device.

In the lower half of an American window is

FIG. 5.—Window tent for the open air treatment at home.

placed the frame to which is attached the awning, stretched over a quarter circle, with a radius of 40 inches.² The frame of the tent does not quite fill the lower half of the window; a space of about three inches is left for the escape of the

² When there is a recess, so that the bed placed parallel to the window cannot be moved close to the window sill, the tent has to be made correspondingly longer and the bottom flaps made long enough to reach under the mattress.

warm air in the room. By lowering the window this space can be reduced to one inch or less, according to need. On extremely cold and windy nights there need not be left any open space at all above the tent frame. The patient's breath will rise to the top of the tent and the form of the

FIG. 6.—Cut of window tent, showing ventilation.

tent aids in the ventilation. The awning is made of stout duck and is waterproof.

The patient enters the tent through a flap which can be made either on the right or the left side of the tent. The lower edges of the canvas that come at the head and side of the bed are long enough to be tucked well under the mattress to exclude the air from the room and protect the patient from draught. The flap is so constructed as to admit of easy access to the patient.

The change of hot and cold air in the window tent takes place in the following manner: *a b* represent the roof of the window tent, it rests on the bed at *b'* and is attached to the window on points *a* and *c*. Now, *d* is the outside air and *e* is the air in the warm room. If *e* is warmer than *d* then the roof of the tent will be warm and will in turn warm that portion of the outside air *d*, which is in contact with the roof *a b*. This warmer air will go in the direction of *b a* and pass out of the tent at its apex *a*. New air from the outside will, of course, take its place, entering in the direction of *d f*, insuring a constant changing of air. The patient's own expired air rising toward the roof of the tent adds to the circulating current of air—*d f g h*.

In order to protect the patient from storms the roof of the tent has been extended slightly be-

yond the window, and a roller curtain has been placed in the window itself. This curtain running from above downwards can be lowered at the patient's convenience. The protruding portion or peak of the tent is, however, not always essential, particularly if the house has a sufficient projection over the window, or the patient's room is located under the eaves in the upper story. If the peak becomes necessary it is best to arrange it, by the aid of hinges, so that it can be folded down and the whole tent can be moved a few inches into the room to facilitate the closing of the window if desirable. This withdrawing the tent for the purpose of closing the window is essential in order that the room may become warm for the patient to dress or to take his cold sponging.

The patient's body is kept thoroughly warm. He only receives the air in his face; the cot can be placed by the window to suit his preference for sleeping on his right or left side, so that he has the air most of the time in his face. A second advantage of this arrangement is that it will not attract any attention from the outside. Thirdly, it can be placed alongside of the window which will be much more convenient for the majority of the poor who have small rooms. If, however, the bed must be placed at a right angle to the window, the flap can be made in the middle of the tent. When the aerarium referred to is used the bed has to extend about one third out of the window and must, of course, invariably be placed at a right angle to the window sill.

The raising of the bed, if such is necessary, to the height of the window sill is a matter of little expense. If the bed is of iron, a few additional inches of iron piping can be attached to the legs by any plumber, or one handy with tools; raising a wooden bed can be accomplished with equal facility. The frame of the window tent can be made to fit any window. Owing to the simplicity of the window tent, it can be manufactured for about half of the cost of that of the aerarium.

As a standard size we find the frame 30 by 30 inches most convenient. If the window tent is to serve the patient only during the night, bed and window tent can be moved away from the window during the day and the window closed. In cases where the recess of the window permits, the tent can be constructed so as to allow the closing of the window at any time.

This window tent will, of course, be of great service to the consumptive sufferer in winter. If he is feverish, or his stay in bed is advisable, he can spend his entire time in the win-

dow tent. If the people are poor, and the room where the consumptive sufferer lies serves as living room for the rest of the family, the fact that the well members need not shiver and yet the patient can take his open air treatment, is of vital importance in many respect. While the room will not be quite as warm as if the window was entirely closed, it will be much warmer than if there was no tent in front of the open window.

Laying aside the economic advantages to a poor family when not being obliged to heat more than one room, the patient feels that he does not deprive his loved ones of comfort and warmth and that he is less a burden and hindrance to their happiness. The other members of the family, on the other hand, feel that they can give to the patient all the air he needs and that he himself need not suffer for their comfort.

In winter, the patient's bed must be covered with a sufficient number of blankets to assure his absolute comfort and warmth throughout the night. Still, this covering should not be so heavy as to press down upon the body and make the patient feel uncomfortable and tire him. The light and tightly woven blanket is a better protection than the loosely woven one. To the poor, whose disposal of blankets is alas! often very limited, it

may be valuable advice to tell them to put several layers of newspapers between the coverings. *Outdoor Life*, of December, recommends to have a dozen layers of newspapers sewed between two layers of flannel. This will certainly make a light and warm covering. From the same journal I reproduce a woolen helmet which the patient, in addition to a sweater, may use in extremely cold weather (Fig. 7).

Some patients will complain that the bright light awakens them in the morning too early and that they have difficulty in going to sleep again. In such instances I counsel the patient to have some light weight, but dark colored material (such as black lisle thread hose), to put over his eyes, and this usually suffices to obviate the inconvenience caused by the bright light.

FIG. 7.—Woolen helmet for sleeping outdoors in cold weather.

The pulmonary invalid should be in communication with his nurse, relative, or friend, who takes care of him, by a bell. He should, of course, have a cuspidor handy to receive his expectoration. I have found that a tightly closing pocket flask, which can be manipulated with one hand, and when not in use placed under the pillow, is the most suitable. The patient can expectorate into such a flask without uncovering himself. I show here my latest model which differs from the former ones by its greater simplicity and durability (Figs. 8 and 9). The flask is made of metal and is, of course, unbreakable; it is oval, about $2\frac{1}{2}$ inches in height and $2\frac{1}{4}$ inches in its largest diameter. It is made according to the principle of the irreversible inkstand, and hot water suffices for its thorough cleaning. It seems to me that any kind of cuspidor which had to stand on the window sill would not be as safe, as there is always a danger of its falling out of the window. A urinal should also be at the bedside so that the patient will not have to leave the bed in the night.

Besides the fact that the patient feels easier when he knows that the rest of his family are not in discomfort because he must be exposed to the cold, there is another advantage in this window tent arrangement whereby the patient's physical and mental condition will be benefited. His pro-

FIG. 8.—Metal pocket sputum flask manipulated with one hand.

longed rest cure in bed will be more endurable when he is permitted to look out on the street and watch life there than when obliged to gaze at the four walls of his room, or simply at the awning, as would be the case with the aerarium.

When arranging for the rest cure on the reclining chair during the day in his half tent in the garden, on the veranda, in the sleeping shack, on the roof, or on a balcony, one should always bear in mind that it is much more agreeable and conducive to the well being of the patient when taking the cure, to have a pleasant view to look upon. In building sanatoria, the greatest attention is paid to the proper selection of the place

for rest cure gallery or veranda. The more pleasing and entertaining the outlook from these places the more certain is one to keep the patients quiet and restful.

It may be asked what results have been attained with the new device. It has not been long enough in use nor tried by a large enough num-

FIG. 9.—Pocket sputum flask taken apart for cleaning.

ber of people to make any positive statement in this respect. One of the writers recommended it to a young tuberculous physician of Brooklyn whom he had the privilege to treat. After very few days of sleeping in the window tent the young doctor assured us that his cough and expectoration had diminished, that his temperature had gone down to almost normal, and that he would not exchange his present mode of sleeping for any other kind, whether sick or well. In a few other cases the results have thus far been equally satisfactory.

There is lastly one more advantage to be derived from the use of this apparatus that is not to be underestimated. Patients who can usually be persuaded with difficulty to sleep with the window wide open will not hesitate when they have this tent as an inducement.

In conclusion, we wish to give a few indications regarding the rest cure and to warn particularly against overdoing it. In the experience of the authors, lying for hours and hours on the back, even in the open air, has resulted in a number of cases in a hypostatic congestion of the lungs. One should always guard against this when prescribing the rest cure in bed or on the veranda. It should be insisted upon that the patient change his position from time to time and take frequent deep inspirations. If the patient is afebrile, or but very slightly feverish, he can rise

from his chair every half hour, or every hour, to take some breathing exercises with movement of the arms, such as has been suggested by one of us in previous publications on the subject.³ This doing something every half hour will make the enforced idleness less monotonous and unpleasant to the majority of patients.

The afebrile patient should, of course, also have some walking exercises, and even the slightly feverish patient should take short walks when his temperature is normal. A good way of determining the amount of exercises we may allow a tuberculous patient is to take his rectal temperature before and after exercising. If, for example, the patient can walk for half an hour with only such slight increase of temperature as must be considered physiological after such exercise, he may the next day walk a little further. If, however, the increase of temperature is pathological, it is an indication that the patient has overdone and he must exercise less the next day. A temperature of about a hundred degrees is an indication for absolute rest. We should, of course, allow the patient to read during his rest cure during the day; but the conscientious phthisiotherapist will even select suitable literature, for in our experience we have seen the temperature rise in otherwise afebrile patients as a result of reading exciting novels and detective stories. All needle work which demands stooping over should be strictly prohibited to women patients.

It goes without saying that one does not wish to expose the patient for eight or nine hours to the cool atmosphere on one of the coldest nights of our eastern winters the first time he tries it. The patient should be gradually accustomed to the exposure to night and day air. In winter he should never be placed in the window tent or on the veranda at night without having been gradually exposed to the open air during the day. The tuberculous patient who has not been accustomed to the open air treatment should therefore at first be placed on the reclining chair in front of the open window or on the veranda during the warmest hours of the day, and preferably when the sun shines. The number of hours of exposure to the open air should then be gradually increased, and after a week or ten days one may begin with a few hours of sleeping in the window tent or on the veranda at night time. The patient will usually have improved from this

³ S. A. Knopf; *Pulmonary Tuberculosis; Its Modern Prophylaxes and the Treatment in Special Institutions and at Home*. F. Blakiston's Son & Co., Philadelphia, publ.

S. A. Knopf; *Lecture on Respiratory Exercises*, delivered before the Medical School of Johns Hopkins University.

judicious aerotherapy so that he will himself be anxious to try sleeping outdoors the entire night. The dread of serious consequences that some patients have when exposed to the cold air for the first time, must always be taken into consideration, and here perhaps more than in any other phase of the management of tuberculous patients, tact and firmness on the part of the physician will accomplish all the desired results.

Whether the patient sleeps on the veranda, in a room with the windows wide open, or in the window tent, I wish to emphasize the point that in winter he should always dress and undress in a warm room and also take his massage and his hydrotherapeutic applications, be they simply friction with cold water, ablutions, or complete douches, in a room with a temperature of at least 72° F.

One more point must be considered. Is this open air treatment by day and by night feasible in all climes? We believe that we can conscientiously answer this question by saying that there are to our minds no regions in the United States where this treatment cannot be carried out. The best proof that it is feasible in our own climate, even in our own city, has been demonstrated by the results obtained at the Riverside Sanatorium on North Brother Island, at the Phthisis Infirmary at Blackwell's Island, and in the tents on the Bellevue Hospital grounds. Even the formerly so much dreaded New England night air has lost its terror to the phthisiotherapist through the admirable work of Dr. Millet, of Brockton, Mass.

That equally good results can be obtained in nearly all climes by the open air treatment for children suffering from tuberculous joint and bone diseases, has been demonstrated in the various European sanatoria for such children. In our own country this has been confirmed recently by the excellent results obtained in the Seaside Tent Camp at Seabreeze, which was established last summer by the Association for Improving the Condition of the Poor of this city.⁴

Let us hope that some philanthropists will arise, or that our health and charity departments will be provided with sufficient funds ere long to give the thousands of consumptive poor adults and tuberculous children of this city sufficient facilities to make use of God's fresh, pure air by day and by night. With ample facilities for curing the curable and taking care of the hopeless tuberculous poor, we will make great strides toward the solution of the tuberculosis problem.

RESECTION OF GANGRENOUS INTESTINE DUE TO A VOLVULUS FOLLOWING A SECOND ATTACK OF APPENDICITIS. INTESTINAL OBSTRUCTION CAUSED BY UNOPERATED APPENDICITIS.

(Concluded from page 371.)

By CLARENCE A. McWILLIAMS, M. D.,

NEW YORK,

INSTRUCTOR IN SURGERY, COLUMBIA UNIVERSITY; SURGEON TO TRINITY HOSPITAL; ASSISTANT SURGEON TO THE PRESBYTERIAN HOSPITAL.

Thirty-three cases are appended to this article. Analyzing them, we find the following facts: Volvuli occurred in six patients, of whom four died and two recovered; kinks occurred in four, of whom three died, and one recovered, and bands occurred in 23, of whom 8 died, and 15 recovered. Out of 33 patients, 15, or 45.5 per cent., died, while 18, or 54.5 per cent., recovered. This is a startling mortality certainly, and is cause for searching investigation on the part of both physician and surgeon, in order to determine what can be done to lessen this appalling result. By consulting the table of the length of time that the obstruction had existed before the operation, we find that this was given in 19 cases, the average of which was four and a half days. Seven patients were operated upon within three days with a mortality of two, or 28.5 per cent., while twelve were operated upon after four days, with a mortality of eight, or 66.6 per cent.! The lesson is obvious: early operation is the only salvation for these patients, and the burden of responsibility rests with the general practitioner, who always sees these patients first. The slightest suspicion of obstruction, which is raised at once by the failure of medical measures, should be the signal for immediate consultation with a surgeon upon whom, then, will rest the responsibility of operating or not. Nothing is more gratifying and certain in surgery than the prompt recovery after early operation of a patient with a simple mechanical obstruction.

In fifteen of the cases the number of previous attacks is specified. In nine cases there was but one attack of appendicitis. In four cases there were four attacks, and in two there were three attacks of previous appendicitis.

Analysis of the cases is as follows:

Cause of obstruction.	No. of cases.	Gangrene of bowel.	Died.	Recovered
Volvulus	6	1	4	2
Kink	4	2	3	1
Band	23	4	8	15
Totals	33	7 (21.2 %)	15 (45.5 %)	18 (54.5 %)
Gangrenous cases.....	7	1	4	3
Appendix acting as band	11	..	5	6

Length of time obstruction had existed before operation; average was 4½ days.

	Number of cases.	Recovered.	Died.
One day.....	1	1	..
Two days.....	4	2	2
Three days.....	2	2	..
Four days.....	3	..	3
Five days.....	2	..	2
Six days.....	4	3	1
Seven days.....	1	..	1
Eight days.....	1	1	..
Ten days.....	1	..	1
	19	9	10

A boy, seven years of age, was admitted to the Presbyterian Hospital on September 5, 1904, with the following history: One year ago he had had an attack somewhat similar to the present one, sharp abdominal pain in the lower right side of the abdomen, nausea and vomiting, prostration, and constipation for five days. Was in bed fifteen days then. Perfectly well until four days ago, when he awoke in the night with sharp, right abdominal pain, and he vomited. His bowels had not moved the preceding day and he had had no appetite. The next day the pain continued; he was prostrated, and he vomited twice. Bowels did not move. The third day, which was the day before admission, he vomited again, and his father said that the vomitus looked yellow and had a fecal odor. His physician had given him an enema that day, with a small fecal movement as the result. On the day of admission the prostration, fecal vomiting, and constipation continued.

Examination on admission showed a well-developed boy, but apathetic, prostrated, with sunken eyes, and drawn face. Vomitus fecaloid. Temperature 101.5°. Lungs normal. Heart's action rapid, 140, and weak. Liver dullness much decreased, almost obliterated. Edge not felt. Spleen not felt. The abdomen is large, prominent, symmetrically distended all over. There is tympany everywhere over the abdomen equally, extending up into the lung resonance to the fourth rib. It is universally rigid, but more marked in the lower right quadrant. It is also slightly tender everywhere, but markedly so over an area the size of a medium sized saucer at the appendix site. Under the lower end of the right rectus there is an indefinite resistance as of a tumor, but it is difficult to diagnosticate accurately on account of the rigidity. No other tumors or masses.

There was dullness in the flanks, but this was not proved to be movable. Slight peristaltic sounds heard over abdomen with stethoscope. Rectal examination elicited tenderness and bulging, but no definite mass could be made out. The patient lay on the back with the knees drawn up, and appeared to be in considerable abdominal pain. Leucocytes 10,000. Marked indicanuria. The diagnosis was at once made of appendicitis with probable general peritonitis, the fecal vomiting being due either to intestinal paralysis or to a mechanical obstruction. The patient was at once taken to the operating room, four days after the onset of the trouble.

Operation at 9 p. m., September 5, 1904, gas and ether being administered. Intermuscular incision over the appendix site. On opening the peritoneum, bloody, clear serum escaped with slight fecal odor. On pushing away a fairly normal

coil of small intestine, a blackish coil came into view. There were no adhesions. Vertical incision over the middle of the right rectus, whose fibres were split. Distended normal small intestine presented. Over toward the right a mass of black, distended small intestine was delivered through the wound. The following conditions were with difficulty made out: The appendix was swollen, red, and from its tip on manipulation a little pus exuded. It was tightly adherent to, and had wound itself transversely about the small intestine. At this point the black area began. Near the base of the appendix on the small intestine a tough adhesion ran across to a second loop of small intestine. This adhesion was evidently of long standing. The portion of small intestine, included between the two adherent points, had twisted completely about itself, with the adhesion as its centre, producing interruption to both the blood current and the faecal stream. The gangrenous gut had not yet lost its glistening character, its walls were oedematous, and it was distended. There was no perforation anywhere. The appendix was rapidly ablated. The boy's condition at this point became alarming and a saline intravenous infusion was begun. In view of his condition it was decided to make an artificial anus after excision of the gangrenous intestine. Two large clamps were placed on the healthy gut just beyond each extremity of the gangrenous portion of the gut and the bowel was divided between the clamps at these two points.

Clamps were placed along the oedematous mesentery, which was then divided beyond the clamps. The gut excised measured 23 inches. The pedicles in the clamps on the mesentery were tied with catgut. The clamp on the lower bowel was seen to be at the ileocaecal opening. The mesocaecum was too short to allow this end to be brought into the median wound, so the clamp, closing the caecal opening, was pushed through the intermuscular appendix wound, and the caecum brought through to the level of the skin, where it was stitched to the muscles by some catgut stitches. The clamp was not removed from the opening into the bowel. The upper part of the median wound was closed by through and through sutures of silk passed with a handle needle. The clamp closing the proximal small intestinal opening was brought into the lower portion of the median wound, and the gut was sutured to the muscles, an inch of intestine being made to protrude beyond the level of the skin. Complete closure of the remainder of the abdominal wound. Holding the protruding intestine up with forceps, a rectal tube was inserted into the lumen of the small gut for five or six inches, and the gut was tied snugly about the tube with a circular suture of silk. In this way it was hoped to prevent soiling of the wounds. There was an immediate escape of gas and slight amount of fluid faeces from the end of the tube. Gastric lavage was given on the table, and a large amount of dark, faecaloid fluid was brought away. Time of operation, one hour. As a result of the infusion of 1,000 c. c. of salt solution the pulse, from being imperceptible, became 140, but weak.

The patient did not vomit that night. The next morning the clamp was removed from the caecum and a solution of soap suds was injected into the ascending colon. The pulse was 140, and the temperature 101.5°. During the night, from the rubber tube draining the proximal small intestine, a small amount of fluid faeces escaped into a bottle, placed at the side of the bed to receive it. The patient vomited faecal material the second night after the operation, so gastric lavage was given, following which half an ounce of magnesium sulphate was left in the stomach, at 10 p. m. At the same time a solution containing an ounce of the milk of magnesia; turpentine, half an ounce; and two ounces of olive oil, were injected into the small intestine fistula. Every six hours thereafter a nutrient enema, containing in addition half an ounce of whiskey, was injected into the caecal opening. During the night there was a large amount of fluid faeces drained into the bottle from the small intestine, and faeces were also passed from the rectum.

September 7th, the second day after the operation, the patient's condition was poor; temperature, 103.5°; pulse, 140, and weak. He continued to vomit, at intervals, faecal material, and was delirious. Gastric lavage and a hypodermoclysis of 500 c. c. of salt solution were given at 9 p. m. Nutrient enemata were continued through the distal fistula.

On the morning of September 8th, the third day after the operation, the condition was much worse; pulse, 150, and weaker; temperature, 104°. Patient vomited faecal material containing curds and melon seeds. Much fluid faeces escaped from the small intestinal fistula. Two intravenous infusions were given during the day and night, but the patient did not rally and died at 3 a. m. No autopsy was allowed.

Death was due either to the sepsis caused by peritonitis, or to the poisoning caused by absorption from the putrid bowel contents. This peritonitis in its turn may have been set up by the passage of bacteria through the walls of the gangrenous gut, which themselves were not perforated at any point. The appendix was not ruptured or gangrenous, so that the peritonitis was not caused by the appendicular inflammation. There was no growth from the culture taken at the time of operation, but in the haste of the operation it may have been badly taken. The continuance of faecal vomiting after the operation was probably due to paralysis of the intestines, caused by the peritonitis, or by overdistention.

The obstruction in this case was due to the adhesions caused by the previous attack of inflammation of the appendix. The present appendicular attack must have been purely a coincidence. Indirectly, however, the volvulus may have been precipitated by the increased tympan-

itic distention and increased peristalsis of the small intestines due to the acute appendicitis.

This case testifies, as do the 32 others in this article, how necessary it is to bear in mind the possibility of a mechanical obstruction, dependent upon the adhesions resulting from a previous attack of appendicitis. If the diagnosis could not have been made earlier, at least the onset of faecal vomiting in this case, twenty-four hours before admission to the hospital, should have been the signal for an immediate operation, in which case the result would undoubtedly have been very different; instead of which the medical attendant lost valuable time in vainly trying to get the bowels to move. The only possible rational treatment of faecal vomiting is the surgeon's knife, and that, too, at the very earliest possible moment.

In the *Archiv für klin. Chir.*, Vol. LXXIII, page 231, the following three cases of intestinal obstruction with gangrenous intestine, following the attacks of appendicitis, are given:

1. A man, sixty-eight years of age, had years before recovered from a severe attack of appendicitis. Symptoms of obstruction suddenly developed. Operation showed that a loop of small intestine was adherent to the tip of the appendix, both together being adherent to the pelvic brim. The intestine was kinked so as to obstruct its lumen. Loosening of this adhesion. Post mortem examination three days later showed gangrene of this loosened adhesion and perforative peritonitis. 2. A man, forty years of age, had had several previous attacks of appendicitis. Symptoms of obstruction had lasted for five days. Operation showed a band stretching from the right parietal peritonæum to the mesoappendix and forming a tense bridge in front of the cæcum. Under this band a loop of the lower end of the ileum had slipped and had become strangulated. This loop, half a metre long, was gangrenous. After dividing the adhesion the loop was brought into the wound and attached there extraperitoneally. Death in six hours. 3. The third patient, a man fifty-three years old, had had twenty years before a severe attack of appendicitis. Five years previously he had had an attack of acute ileus which had finally yielded to high enemata. Constipation and attacks of intestinal colic were frequent since then. Symptoms of obstruction appeared for eight days previous to operation, which revealed adhesions in the cæcal region. At the level of the parietal peritonæum a loop of small intestine several inches above the junction with the cæcum is seen to be kinked to a right angle, and at the acutest point of the angle there is a gangrenous area out of two perforations in which fluid faeces escaped. The gangrenous area with the appendix was resected. Death in two days from increasing peritonitis.

L. Bérard (*Bull. méd.*, Paris, 1902, XVI, 286-288) successfully operated in a case of obstruc-

tion, seven years after an undoubted case of appendicitis, where he found many adhesions and a complex volvulus.

Broca writes a very interesting article in the *Gaz. hebdomadaire de méd. et de chir.*, 1901, XLVIII, 445-450: A patient had had seven years previously a severe attack of appendicitis, which was treated medically and from which he recovered perfectly. July 7, 1900, he was seized very suddenly with all the symptoms of obstruction, for which he was operated on in twenty-four hours. Median laparotomy. Band found attached by one end to the intestine, and by the other to the pelvic wall, causing bending and compression of the loop, the two extremities of which were adherent. Division of the band and separation of the adhesions. A second compressing band was found in the right iliac fossa. Recovery.

J. B. Murphy (*Chicago Clinical Review*, 1895, V, 645) reports that in June, 1895, a patient had a severe attack of appendicitis from which he was in bed four days. Following this he had several other attacks of the same difficulty. In January, 1896, after an attack of complete obstruction, he was operated upon. On separating a mass of adherent intestines, there was found an almost completely flexed loop. Recovery.

G. Marion (*Gazette des hôpitaux*, Paris, 1900, page 1439) reports two cases: The first patient had had a number of years before an appendicitis, for which there had been no operation. In July, 1900, operation for obstruction of several days' duration. The small intestines were found plastered to the cæcum in an almost inextricable mass. Death. Case V.—This patient had had three antecedent attacks of appendicitis, the last one a month previously. Obstruction existed for four days. Operation.—In cæcal region many dense adhesions. Artificial anus. Death. Autopsy showed, in the mass of adherent intestines about the cæcum, a volvulus absolutely constricting the bowel.

Hermes, in the *Deutsche med. Wochenschrift*, 1901, page 368, reports the case of a twenty-two year old girl who for a long time, had had various disturbances of the stomach and bowels. She was suddenly seized with severe pains in the abdomen, shock, tenderness, vomiting, etc. The diagnosis lay between perforative peritonitis and ileus. Median laparotomy revealed bloody, serous exudate in the peritoneal cavity and dilated intestines. No lesion was discoverable in the stomach or gall bladder regions. Collapsed intestine was found in the cæcal region, where it was discovered that a loop of small intestine, about 30 cm. long, had become completely constricted by an appendix which was adherent by its tip to the cæcum. Resection of the appendix, in whose tip there was found a small encapsulated empyema. Recovery.

Courvoisier (*Archiv. für klin. Chir.*, Vol. LXVI, page 470) reports a similar case: A woman, fifty-seven years of age, had had two previous attacks of appendicitis, the last six years before. Symptoms of intestinal obstruction had existed for four days. After eventration in the right region there was found a much dilated loop of small intestine,

to whose base the tip of a fibrously degenerated appendix was attached. In the niche between this dilated loop and the cæcum there lay a completely collapsed piece of small intestine, strangulated by this overlying appendix. The direct continuation of this collapsed intestine was found to be the dilated loop first met with. There was found in addition a twist of 180° of the intestine above the bridge. No gangrene. Ablation of the appendix. Death in twelve days from pneumonia. Courvoisier also reports a case of a ten year old boy who two years before had had appendicitis. Obstruction for three days. Operation disclosed a band joining two portions of intestine together. A horseshoe shaped loop had insinuated itself under this band and this loop had become twisted 180° about its mesentery. No gangrene. Recovery.

Weir (*Medical Record*, 1903, Vol. LIII, page 801) mentions an instance of strangulation of intestine beneath a bridge caused by the adherent appendix. Fortunately operation was performed before the strangulated intestine had become gangrenous, so that the removal of the appendix was followed by a relief of all the symptoms.

Delore (*Société des sciences médicales, Lyon médical*, 1902, No. 32) reports a case of chronic obstruction caused by a band and adhesions, due to an attack of peritonitis, six months previously. Recovery.

Cuiti (*Rivista critica di clinica medica*, 1902, No. 2) found a piece of small intestine, 90 cm. in length, strangulated and gangrenous beneath an adherent appendix, the site of a previous inflammatory attack. Resection. Drainage. Recovery.

Brown (*Lancet*, October 12, 1901) reports the resection of three feet of gangrenous intestine, due to a band, the result of a previous attack of appendicitis. Recovery.

Hepner (*Beiträge zur klin. Chir.*, 1902, Vol. XXXVI, page 306) reports a case, following an attack of appendicitis three years previously. Obstruction for two days. Patient in bad condition. Artificial anus formed. Necropsy revealed a firm band, 20 cm. above the valve of Bauhini, which ran from the intestine to the parietal serosa and produced a complete kink in the intestine.

Crook (*Memphis Medical Monthly*, February, 1904, page 60) gives the case of a girl, aged ten years, who had had in September, 1902, typhoid fever, during the course of which she had a severe attack, lasting for several days, of pain, with vomiting and tenderness over the appendix. After recovery from the fever, she had slight recurrences about once a month of the pain and vomiting. In February, 1903, she had a second undoubted attack of appendicitis. A third attack in April, 1903, kept her in bed for two weeks. On May 17th, one hour after eating a hearty meal, she was seized with agonizing pain in the umbilical region which shot over toward the right side. This was followed by nausea and vomiting. Constipation became complete. Operation on the sixth day of the illness. The entire con-

tents of the right iliac fossa were found matted together and bound by firm adhesions, amounting in some instances to fibrous bands. The appendix was turned on itself and firmly adherent to the under surface of the caput coli. The colon was firmly bound to the posterior abdominal wall, and required unusual force to free it. The appendix was removed, adhesions and bands were broken up, and intestines separated. Recovery.

Lejars (*Bull. et mém de la soc. de chir. de Paris*, Vol. XXX, No. 13, page 380) reports the case of a patient with two attacks of appendicitis at the age of fifty years. At the age of seventy-two years, with no intervening appendicitis, ileus came on, caused by multiple twists of the intestine and torsion of the mesentery, due to bands emanating from the old pericecal inflammation. The appendix was found cut in two and the distal end grafted upon the neighboring peritonæum. Death.

Potherat (*same publication as the preceding*, Vol. XXX, No. 16, page 460) reports three cases of true internal strangulation, the anatomical mechanism being identical in all: 1. Eight year old infant with a six days' occlusion. Appendix found stretched transversely from the right iliac fossa to the prevertebral region, where it was firmly adherent. Between this adhesion and the free edge of the mesentery there existed a bridge, under which a loop of small intestine had become engaged and completely compressed. 2. A man, seventy years of age, had an appendicitis in his fiftieth year. Obstruction for seven days. Very great distention. Operation showed the same arrangement as in the first case. Death. 3. Young girl. Three years previous, severe attack of appendicitis lasting twelve days. None since. Present attack existed five days before operation. Fæcaloid vomiting. Pulse, 160. Taken by her physician to have acute appendicitis. The adhesion of the inflamed appendix had led to a hiatus, under which the intestines became caught and strangulated. Death.

Ross (*Canadian Jour. of Med. and Surg.*, June, 1903, page 385). Boy was seen forty hours after the onset of symptoms of vomiting, obstinate constipation, and tenesmus. The abdomen was distended and hard. The case looked very much like one of peritonitis following perforation of the vermiform appendix, but the absence of fever and the presence of tenesmus rather pointed against this diagnosis. Operation disclosed a loop of dark colored intestine about 18 inches long which had slipped through under a band which proved to be the appendix the tip of which had become adherent to a spot on the mesentery of the small intestine. Removal of the appendix and freeing of the bowel. Recovery.

Dr. Joseph A. Blake has kindly given me the following case, the result of recurring appendicitis: At the time of operation, the girl, aged eighteen, was also suffering from acute appendicitis in the third day of the attack. Operation disclosed the appendix acutely inflamed, stricture, distended, and fresh adhesions. A loop of ileum, twelve inches long, was found strangulated under a band (adhesion), and gangren-

ous. Appendectomy: resection of gut; end to end union with the Murphy button. Recovery.

Dr. F. H. Markoe (*Annals of Surgery*, Vol. XIX) reports a case of acute obstruction occurring in the course of acute appendicitis, in which the obstruction was due to an adhesion between a perforated and inflamed appendix and a coil of small intestine which had become acutely strangulated. Death resulted from an extension of the already existing peritonitis.

Makins (*Lancet*, January 16, 1904, page 157). A girl, six years of age, with vomiting and constipation of six days' duration. Normal temperature, pulse 114. Upper part of the small intestine much dilated, and below this a loop was found strangulated behind the appendix, which was bulbous at its extremity and adherent to the anterior abdominal wall. Recovery.

Kocher, in the article which was quoted in the beginning of this paper, reports two cases, both due to bands from old adhesions, resulting from previous attacks of unoperated appendicitis. One case had had symptoms of obstruction for ten days and gangrenous gut was found. This case finally recovered, although convalescence was complicated with an abscess. The second case had a firm band binding the intestine so tightly as to completely obstruct its lumen. Recovery.

David MacEwan (*Brit. Med. Journal*, June 4, 1904, page 1310). A woman, twenty-eight years of age. Vomiting and constipation for six days. Pulse, 140, and weak; temperature, 97.6°. Complained of frequent paroxysmal pain above and to the right of the navel, extending round to the back. Abdomen moderately distended and showed marked bulging in the iliac regions. It became tense during the attacks of pain, and peristalsis was visible. Tenderness was marked on deep palpation, but no tumor could be felt. No result from large enemata. She had had no previous serious illnesses. Operation. In the right iliac fossa, a loop of bowel was found to be snared under the vermiform appendix, which was firmly adherent by its free extremity to the mesentery, close to the ileum, and about three inches from the lower end of the latter. There were no signs of recent inflammation of the appendix. The implicated portion of bowel was easily liberated and the appendix was then removed. The latter was above the average length and, for about an inch at its extremity, it was impervious and cordlike. Recovery.

O'Brien (*St. Paul Med. Journal*, 1903, page 618) reports the case of a man who gave a history of much previous digestive disturbances extending over many years. He was suddenly seized after luncheon with violent pain in the left lumbar region. He had a drawn, cold, ashy face, wet with perspiration; pulse, 74; temperature, 98°; nauseated. The next day he vomited greenish material; temperature, 99°; pulse, 56. Operation disclosed a large amount of fluid, and a knuckle of dark, almost black, intestine. This loop was followed up for four inches to an inflammatory ring of omentum. After releasing the constriction, the color came back into the gut. The appendix

was found glued to the cæcum and obliterated. Recovery.

Lapeyre (*Rev. de chir.*, 1903, page 608) reports three cases. The first patient had had brief, painful, abdominal crises. In this case the appendix itself was the strangulating agent. Death. The second case was due to old appendicitis, but its mechanism was not discovered at operation. Death. The third case showed a volvulus of a small intestinal loop, which had passed in front of the great omentum, which was itself buried in the midst of a mass of intestines. The great omentum occupied this abnormal position by reason of adhesions, which fixed its inferior angles to both iliac fossæ. The adhesion to the right was particularly firm. The diseased appendix had become sheathed with infiltrated and diseased omentum. Recovery.

For the purpose of completing the entire subject of intestinal obstruction, due either to previous unoperated appendicitis, or following an operation for appendicitis, I have appended conclusions drawn from the study of the 86 cases of obstruction, following appendicitis operations, published in the *Medical News* of September 3 and 10, 1904:

1. The rarity of intestinal obstruction in comparison with the innumerable operations for appendicitis is noteworthy.

2. Obstruction may follow the interval operation. Eight cases, or nine per cent., belong to this category.

3. Obstruction is most apt to follow appendicitis with abscess formation. Sixty-nine, or eighty-one per cent., were of this class. Hence the greater necessity for early operation.

4. Mechanical obstruction may come on at any time after the appendicitis operation, when the diagnosis from that due to peritonitis may present great difficulties. When in doubt operate, for many patients have undoubtedly died unoperated upon, with an unrecognized, mechanical obstruction (with or without peritonitis) where the erroneous diagnosis was made of simple, uncomplicated peritonitis.

5. Obstruction may occur years after the original attack or operation (e. g., ten cases occurred two years after the operation), when it may come on suddenly in perfect health, or preceded by a period with symptoms denoting partial (chronic) occlusion, the right interpretation of which symptoms from a prophylactic standpoint is of the greatest importance.

6. There may be several attacks of true mechanical obstruction. In the 86 cases, several attacks occurred in five, or 0.8 per cent., of the 57 patients who survived the first operation for obstruction.

7. Of the 86 patients, 57, or 66.3 per cent., recovered after operations for occlusions; 29, or 33.7 per cent., died.

8. The small intestine was occluded in all of the fifty cases where it was noted. The causes were given in 53 patients, as follows: constriction by bands in 28 patients; volvuli in ten; kinkings or angulations in eleven; and internal herniæ in four cases.

9. Gangrenous bowel was encountered in five cases, necessitating resection, resulting in three recoveries.

Résumé of the 33 cases of intestinal obstruction following attacks of unoperated appendicitis, reported in this article:

1. Volvuli occurred in six patients of whom four died, and two recovered: there were kinks in four, of whom three died, and one recovered: bands occurred in twenty-three, of whom eight died, and fifteen recovered.

2. Of 33 patients, 15, or 45.5 per cent., died, while 18, or 54.5 per cent., recovered.

3. Of seven operated upon within three days, two died, or 28.5 per cent., while twelve were operated on after four days, with a mortality of eight, or 66.6 per cent.

4. These statistics point a forcible moral: Operation must be performed earlier on these patients! The burden of responsibility rests with the general practitioner, who always sees these patients first, to summon at once a surgeon, when, after a short trial, medical measures fail to relieve.

5. Seven patients, or 21.27 per cent., had gangrenous intestine, four of whom died, and three recovered.

6. The appendix itself acted as the obstructive band in eleven cases.

7. Prophylaxis consists in carefully regulating the diet of every patient for several months after an attack of appendicitis. Constipation and attacks of colic should be promptly and vigorously treated and anxiously watched. Abdominal massage may be used to release adhesions due to the antecedent periappendicular inflammation.

8. Symptoms due to chronic obstruction should be distinguished from intestinal indigestion and treated accordingly.

Addenda.—Since I wrote the foregoing article, a thesis has appeared by Maurice Garayon, presented at the University of Lyons, entitled *Des acclusions intestinales d'origine appendiculaire*. In this are reported 19 cases, eleven of which had followed attacks of unoperated appendicitis, with seven recoveries and four deaths, and eight cases followed operations for appendicitis, six of which

ended in recovery and two in death. Three additional cases also are reported in the *Archiv für klin. Chir.*, Vol. LXXIII, Heft 3, page 804. Two followed unoperated appendicitis with one recovery, while one case was subsequent to an operation for appendix abscess, there being gangrenous intestine found at the time of operation for obstruction. Following this latter operation, a fecal fistula developed, the attempt to close this two months later resulting in death. Six cases of obstruction in children are recorded in the *Archiv für Kinderheilkunde*, Bd. XXXIX, Heft 4-6, page 247. Three of these cases of obstruction followed attacks of unoperated appendicitis, with two deaths and one recovery after operations for the obstructions. Three were subsequent to appendicitis operations, all the latter patients dying.

50 EAST FIFTY-THIRD STREET.

RETARDED DEVELOPMENT OF SPEECH IN YOUNG CHILDREN.*

By G. HUDSON-MAKUEN, M. D.,

PHILADELPHIA,

PROFESSOR OF DEFECTS OF SPEECH IN THE PHILADELPHIA POLYCLINIC HOSPITAL AND COLLEGE FOR GRADUATES IN MEDICINE, AND LARYNGOLOGIST TO THE DOUGLASS MEMORIAL HOSPITAL.

The normal child begins to understand spoken words during the closing months of the first year, and begins to make intelligent use of them soon after the middle of the second year. If these beginnings of the development of speech do not appear promptly in the order named a careful search should be made for the cause of the delay. We first look for structural irregularities in the peripheral organs of speech, the tongue, palate, lips, teeth, nostrils, and pharynx. Is there free nasal respiration, and are there no mechanical obstructions to the action of the organs of speech? Then we look for defects in the nerve supply of these peripheral organs. A slight paretic condition of the nerves of the tongue, palate, or lips will often result in very marked defects of speech. Closely related to the peripheral organs is the central or cerebral speech mechanism, and even more closely related to the latter are the intellectual centres of the brain, so that, as Max Muller has said, "language and thought are inseparable. To think is to speak low. To speak is to think aloud." Faulty hearing power will also naturally suggest itself, and in many cases the first suspicion of deafness may be aroused by the retarded development of speech.

If a child does not hear words spoken, he will not understand them, and if he does not understand

* Read before the Medical Society of the State of Pennsylvania, in Pittsburgh.

he will not use them. There will be no development of speech and there will be, in consequence, no development of all that portion of the brain and nervous system which presides over the faculty of speech. The intellectual centres, also, being deprived of the stimulus which comes from the use of spoken and written language, will share in the tardy development, and we shall have a feeble minded as well as a deaf child, the former condition being a natural consequence of the latter. The moral nature also becomes perverted. The child is out of harmony with his environment. He does not understand what is expected of him. The nervous energy that should be expended in normal activity is wasted or misdirected. He grows sullen and morose, or develops tantrums. In either case he generally enlists the sympathy of the various members of the household, who proceed to spoil him by granting his every wish, and withholding all forms of discipline. He frequently becomes vindictive and destructive, and requires most careful supervision.

The cause of the condition may be by no means easy to determine, and the diagnosis and prognosis are equally difficult. Is the child mentally deficient because of some organic cerebral defect, or is he merely mentally undeveloped because of his inability to hear and use articulate speech. Only the other day I saw a child in an institution for imbeciles and idiots, who had no organic defect of the brain, but who had failed to develop intellectually because she was hard of hearing and could not talk. Many similar cases doubtless find their way into such institutions because of mistakes in diagnosis, and thus fail to receive appropriate treatment. On the other hand our regular schools have many inattentive and backward children whose only defect is partial deafness. Dr. James F. McKernon, of New York, reports having examined, in a single institution, 154 children, ranging from four and a half to sixteen years of age, and having found 30 unsuspected cases of deafness. This would seem to emphasize the importance of a thorough examination of the hearing of school children in order that remedial agents may be employed, in cases of incipient deafness, before the condition becomes unalterably established, and the speech becomes impaired.

It must be remembered that partial deafness in young children or deafness for only a few sounds is sufficient to interfere with the normal development of speech. As a rule the child speaks the language that he hears, and defects of speech always suggest a corresponding defect of hearing. If the defect of hearing is so marked as to render only a few sounds audible, the child naturally fails to get the meaning of spoken words and sentences,

and, as a result, he will soon cease to make practical use of them. Failing to understand general conversation, he gradually stops listening, and the brain finally loses its power to comprehend the meaning of spoken language. While there may not be absolute deafness for all sounds and noises there is a kind of intellectual deafness which renders conversation inaudible and meaningless.

By way of illustration I beg leave to report and exhibit a case that has recently come under my observation through the courtesy of Dr. William M. Beach, of Pittsburgh.

One year ago this child, Sarah M., aged 5 years, could not understand or use spoken language. She could say, at dictation, a few words, such as *mamma*, *papa*, *baby*, but she never used them voluntarily, and she showed no appreciation whatever of their meaning. When spoken to she was perfectly indifferent. If her attention was claimed she would look up into your face without changing her expression, or comprehending in the slightest degree what was being said to her. She did not seem to know even her own name. On the other hand, she was very skillful in pantomime. She could make her every want known by this method of communication, and she could understand its use in others. For example, when asked, on one occasion, if she would like to have a paper and pencil to write with, she gave no sign of comprehension, but when the paper and pencil were shown to her her face immediately lighted up, she came forward, took them and began at once to make little connected characters. When it was suggested to the mother that the child might be deaf she declared that it could hardly be so, for she gave positive evidence of hearing and enjoying instrumental music.

Physically the patient is somewhat below par. She is well formed but undersized, weighing only three pounds at birth and thirty pounds now at 6 years of age. In her first year she had measles, pneumonia, and two attacks of whooping cough, and, in her fifth year, bronchitis and la grippe with an acute unilateral otitis media. She takes cold easily and each attack is attended by more or less congestion in the region of the drum membranes. She did not walk until she was two and a half years of age, and it was thought that her delayed speech development was due to her slow physical development, and that her talking like her walking would come with time, and, to use a common expression, she would grow out of the difficulty, a thing by the way which never happens. There is no such thing as growing out of a defect of speech. One must get out or be helped out.

After a careful study of the case, covering a period of more than a week, it was found that the patient could hear and enjoy musical sounds, but that she had no conception whatever of the meaning of a single syllable of speech. Her own name had no meaning to her. The words *mamma* and *papa* failed to designate these individuals, and yet there were evidences of at least a partial hearing of the sounds of which the words are composed. The patient could hear, "but hearing could not understand," and failing in the appreciation of auditory

speech she was rapidly developing so called visual speech. The eye was taking the place of the ear in conversation, and she herself spoke by means of pantomime. The condition was of gradual onset and development, and probably the result of faulty or partial hearing due to a defective auditory apparatus, which in turn was the result of her various illnesses, accompanied by ear complications, during her second year, when the cerebral zone of speech undergoes its most important developmental changes.

Assuming the diagnosis to be correct the practical question as to treatment was, how should we proceed to develop the patient's perceptive faculties of speech? How could we teach the child to understand the meaning of words and sentences which she could only partially hear and which she was gradually ceasing to hear altogether because they had no meaning to her, and because she therefore had no use for them? Naturally the treatment suggested was two fold, first, the improvement, as far as possible, of the peripheral organs of hearing by the well known methods used for this purpose, and, second, the training of the central auditory and speech mechanisms, by whatever means in our power, and the substitution of the use of the auditory for the visual mechanism which was being employed for the reception of language.

Local applications were made to the nasopharynx for the relief of a slight catarrhal condition in this region, and gentle inflation of the middle ears was performed, with massage of the drum membranes through the external auditory canal by means of the electric masseur. Increased hearing power invariably followed this treatment. In order to develop the central auditory and speech mechanisms, galvanism was applied to the head and an effort was made to discourage all forms of visual perception by excluding, as far as possible, lip reading and pantomime, and encouraging the use of the faculties of hearing and oral articulation. All this was not so easy as it seems. The patient, as I have said, was unused to any form of discipline, and was not disposed to change her habits without some protest. Her prejudices, however, were gradually overcome, so that she soon began to take kindly to every phase of the treatment, even the local measures employed for the relief of her hearing. Her training was of the most rigid sort. She was taken away from her mother, and given over to a teacher, who followed my directions in all respects. She was brought to my office on alternate days for treatment and suggestions as to training. The greatest difficulty was encountered in our efforts to have her try to utter articulate sounds, and our first attempts were met with absolute failure. It will be remembered that she had no auditory impressions of speech and so a beginning had to be made through the tactile sense in the same manner as deaf mutes are taught to speak. After a few sounds had been made in this way and their symbols recognized, as for instance the vowels *a* and *o*, short words were given and their significance explained by means of pantomime. She was then taught the names of ordinary things about her, and gradually required to ask for things that she wanted by repeating the names. In this way she acquired a little vocabulary of words that she could use, but could not hear when used by

others, and it remained to teach her to hear and to understand their meaning.

Dr. Victor Urbantschitsch, of Vienna, was I think the first to call attention to the importance of teaching the partially deaf to hear by the development of latent hearing power in the cerebral zone of language. It is well known that if we deprive a person of one of his physical senses the remaining senses will develop greater acuteness. The blind, for instance, learn to hear more acutely because of their blindness, and similarly this child had learned to see more clearly because of her deafness, and she was rapidly growing to depend upon her vision to do for her things that her hearing should do. Naturally, on the same principle, if her vision was curtailed, her hearing should improve with practice, and this is just what happened. She was not allowed to look at the lips of persons speaking. All forms of pantomime were gradually excluded from her life. If she wanted an article of food she had to ask for it or at least try to name it, and she went without many a good thing at first rather than conform with this requirement. Her teacher was instructed not to understand her former methods of making her wishes known, and she was, therefore, compelled to speak or go without things that she had been accustomed to have. In this way she soon became interested in words and in their meaning, and she began to give attention to them and to listen. It was found that after she really knew a word and its meaning she could hear it if only whispered near her ear, and the Urbantschitsch method of repeating words and sentences frequently and distinctly close to the ears, to develop their auditory impressions in the brain, was pursued with gratifying results. It was found that loudness was not necessary, and that distinctness, using the natural forms of speech, as far as possible, was of greater importance.

No electrical device for magnifying the sounds of speech was used for the reason that, so far as I know, nothing has yet been perfected to a sufficient degree to make it practicable. The metallic character of the reproduction of speech in graphophones as now constructed renders them useless and in some instances probably harmful for this purpose. It is quite possible, however, that electric appliances will in time prove to be of great value in this line of work, but at present nothing can equal the natural speaking voice of the teacher.

Our patient was under this special training for about ten months, and the results have been most satisfactory. She is now learning to hear and to understand, and she is also learning to talk. Articulate speech has, for the most part, taken the place of pantomime as a mode of expression, and her speech is quite intelligible and well modulated. Equally marked also is her improvement morally, mentally, and intellectually. Her nature is changing completely from that of obstinacy to amiability, and her mentality is already on a par with that of the average child. A new world of thought has been opened up to her, and her enjoyment of life is already far greater than that of other children of her age. Her training is now being carried on successfully by her mother at home, and we have every reason to hope for still greater improvement in the future. Her hearing may never be acute, but it is

already of great value to her, and her speech, as you see, differs but little in many respects from that of the normal child.

CONCLUSIONS.

First.—Retarded development of speech in young children may be the result of structural irregularities in the peripheral organs, impaired respiration due to nasal, postnasal, and pharyngeal obstructions, paresis of the nerves supplying the organs of speech, and not infrequently to some disturbance of hearing not necessarily amounting to absolute deafness.

Second.—Retarded development of speech always results in defective mentality.

Third.—The treatment consists in the removal of any obstruction that may exist in the peripheral organs and in the systematic training of the auditory and speech centres by the use of specially prepared vocal exercises.

Fourth.—A child may be taught to hear in exactly the same way as he is taught to read and write.

ACTIVE AND PASSIVE EXERCISE IN THE TREATMENT OF SYPHILIS.

By NATHAN T. BEERS, M. D.,
BROOKLYN,

MEMBER OF THE AMERICAN UROLOGICAL ASSOCIATION, AMERICAN MEDICAL ASSOCIATION, MEDICAL SOCIETY OF THE COUNTY OF KINGS, LONG ISLAND MEDICAL SOCIETY; LIFE FELLOW OF THE SOCIETY OF SCIENCE, LETTERS, AND ARTS, LONDON, ENGLAND.

Some months ago, in one of the weekly journals, the opportunity was given to enjoy some very interesting observations on the beneficial effects derived from active, out of door exercise in the treatment of syphilis. The writer was an English gentleman whose practice included a majority of the students in one of the large British universities, and I sincerely regret being unable at the present moment to lay my hand upon the article in order to accord the credit due him as well as to quote him exactly in his remarks. However, my notes made at the time, will give a general idea of his views.

He has observed in his practice among the students that the athletes under treatment for syphilis require much less treatment and suffer fewer secondary symptoms than the sedentary students suffering from the same disease and taking the same course of treatment. He finds that the active, out of door man will stand the largest doses of mercury and iodine, when required to do so, with little or no discomfort or show of poisoning, and seems to pass to a satisfactory and permanent cure without interruption. On the other hand, the sedentary

student, although he may be most persistent and earnest in his treatment, usually does poorly, suffers much from annoying secondaries, and soon becomes saturated with the drugs used. The writer lays this saturation at the door of incomplete elimination of the drugs employed.

During the past few years in which I have confined myself to special work, I have continually observed, both in private and in clinical cases of syphilis, the truth of our English brother's deductions. I have seen many cases which were doing poorly even under the fullest and most persistent treatment, clear up nicely after a prolonged vacation in the open air or on the patient's changing from a sedentary life to one of activity in the open. The importance of this factor in the eradication of syphilis cannot, in my opinion, be overestimated. We see constantly the good effects of air and sunshine in tuberculosis, a disease not greatly unlike syphilis in some of its manifestations; and, while all of the text books speak of the value of active, out of door exercise and sunshine in the treatment of syphilis, there are but few of us who make it a point to bring the importance of these valuable adjuncts in the treatment of the disease forcefully before the patients' minds.

That mercury and iodine are active irritants in the human system cannot be disputed. We have been taught for many years to follow a dose of calomel, given for the relief of hepatic congestion, or what not, with a draught of some saline water; and yet the poor syphilitic is stuffed full of mercury in ever increasing doses until the system rebels, without thought of its potent effect for bad.

In writing of the causes of arteriosclerosis, Dr. Drennen, of Hot Springs, Ark., in the *Journal of the American Medical Association*, speaks very plainly of the effects of uneliminated mercury in the human system, and I take this opportunity of quoting a part of his paper. He says:

"I have long been persuaded that arteriosclerosis does not depend on any specific irritant for its production, but in all cases a combination of elements enters as causative factors. Any agent or combination of agents that is continuously left to circulate within the vessels, which is foreign to normal cell life, will sooner or later be followed by the very changes now under consideration, no matter whether said agent or agents be alcohol, lead, syphilis, autointoxication, or otherwise. To me it is passing strange that a drug like mercury, which is more commonly used in the treatment of syphilis than any other, and has been for ages past, has not been considered one of the chief agents in the production of arteriosclerosis. When we come to consider the fact, it would be almost marvelous if

at times we did not recognize the possibility, and even the very strong probability, of such being true, when we know so well the method commonly adopted by the profession at large to-day in the administration of mercury for the relief of syphilis.

"What has been the custom and teaching of some of our best writers regarding this subject for the past quarter of a century? Have we not been led to believe that the so-called tonic treatment of syphilis with mercury was the only royal road to success? Has it not been the practice of many physicians to prescribe mercury for a period of two years, practically without interruption?

"I maintain that mercury is a metallic poison and altogether foreign to normal cell production, and when it is thrown into the vessels, and there left to circulate for many months, and even years, whether done on the advice of a physician or through self prescribing, we shall find an agent that is just as capable of producing arteriosclerosis as syphilis or any other agent.

"So many times has it happened that patients have come to my office who have been under continuous syphilitic treatment for many years, and, after having given a complete history of the affair, draw from their pockets a little bottle of mercury pills, or of some other pharmaceutical preparation, and relate with painstaking care just how much of this very much abused drug they have been taking during the past three or five years—daily, as the case may be—practically without interruption. It is common enough, I assure you, to warrant me in the belief that to-day more persons are treating themselves for syphilis than are under treatment by regular physicians. With this reckless, senseless, and indiscriminate use of a drug like mercury, need we expect otherwise than to find arteriosclerosis resulting, particularly so when combined with one of man's oldest and most treacherous enemies, syphilis?"

While too much attention and study cannot be devoted to the introduction of mercury into the system, at least an equal amount should be expended in securing its dissemination throughout the tissues and its thorough and final elimination. This point cannot be too strongly emphasized. The proper treatment and the subsequent health of the patient depend almost as largely upon the elimination of the drug as upon its introduction. We find many patients, who, although saturated with the drug, are receiving no relief whatsoever from their symptoms, but are rather tending toward retrogression and debility. The slightest increase in their tonic dose seems to add to their trouble and they promptly develop poisoning symptoms. These cases are

almost invariably seen in sedentary patients. A short course of saline laxatives combined with some form of regular, out of door exercise, such as, horse-back riding, walking trips into the country, out of door games, or a sea trip, stopping the mercury entirely, will very shortly bring back the ruddy flush of health to the cheek, dispel the "blues," and leave the patient well prepared for further treatment when indicated.

The question is often asked, What shall we do with those cases in which active exercise in the open air is impossible,—where the patient cannot or will not follow the doctor's advice? The answer is simple: massage. Here it is that massage offers its greatest advantages. A cold dip in the tub, a brisk rub down with a rough towel, and an hour of thorough massage with Swedish movements administered by a man who understands his work, if taken regularly and for even a short period, will prove very valuable in handling these cases. The circulation is thoroughly aroused to perform its functions, the tissues receive their proper nourishment, quiet sleep is assured, and the patient enjoys a feeling of well being wholly satisfactory to both the doctor and himself. When necessary the administration of mercury or iodine may be reinaugurated and the doses run up to surprising quantities without the slightest distress or discomforting results.

On seeing a case of syphilis for the first time, I make every effort to impress upon the mind of the patient the importance of air, sunshine, and exercise in his treatment. And on each succeeding visit the advice is repeated until he is convinced that his cure depends in a great measure upon his own conduct. When the importance of an active, out of door life is thoroughly impressed upon the patient's mind, he will usually become an ardent supporter of your theory and active in his own welfare. It is usual for these primary cases to undergo, during the first few weeks succeeding a positive diagnosis of their disease, a most harassing depression of spirits, and the physician who supplies the patient with something to do for himself during this period goes a long way toward gaining the confidence of his patient.

Look into your patient's habits; study his surroundings; advise him regarding his food and clothing, his bathing and his sleep. Limit his tobacco, interdict alcohol, and eliminate harmful companions, both male and female. Instruct him in his personal hygiene and acquaint him of his dangers to others with whom he daily comes in contact. If he is inclined toward athletics, foster the spirit to the best of your ability. Encourage him in golf, tennis, riding, bathing, fishing, baseball, rowing, and, best of all, walking across country. Induce

him to walk everywhere he goes, winter or summer, fair weather or foul. When cold weather comes on, advise indoor exercise with dumbbells twice daily until a free perspiration is started, then a quick bath in cold water followed by a brisk rub down with a rough towel. If within the limits of the patient's purse, horseback riding, even indoors, may be found very beneficial in the winter months, if taken regularly. Many of the clubs offer splendid opportunities for indoor exercise on their hand ball courts.

In the case of sedentary patients, every effort must be made to change their habits and surroundings. The clerk who has no time from his desk for exercise, may often times exchange his job with the collector. The delivery wagon offers plenty of air and sunshine for the poor store keeper who is not proud. Where a man is confined to his office or at the bench all day, induce him to spend his evenings in long walks between supper and bedtime. Give him a pedometer and insist upon his submitting to you a record of his daily exercise. His Sundays may be spent to the best advantage in the country.

It is not my purpose or intention to discuss in this short paper the treatment of syphilis by medication. My desire is simply to remind those who are called upon to treat the disease, of the far reaching benefits to be derived by combining with the orthodox medication *regular* active, or passive exercise.

Few diseases offer better possibilities for a cure than syphilis when properly and systematically treated. General practitioners are often prone to look upon syphilis lightly. Their treatment of the disease is tentative. The old mixed treatment prescription and the protoiodide pill are often used improperly, and while their benefits are most gratifying at times, the results are rarely permanent. And yet the doctor is not wholly to blame; these patients are usually "short stayers," and it is almost impossible—especially so in chronic cases—to impress upon them the importance of systematic treatment. In all cases of syphilis, seen privately, a yearly contract is advisable, the patient paying for his treatment quarterly in advance. The doctor is thus enabled to watch the case carefully and regulate the treatment, and the patient is more assured of the probability of his cure.

For the first year or more, I believe the mercury is best introduced by means of inunctions. The entire body, including the head, hands, and feet, is divided into sections and each section rubbed consecutively daily until the "gums are touched" or the patient's bowels, becoming irritable, give hint of saturation. I have found the average number of rubs required to be about sixty, but some cases

will stand as high as eighty or ninety. The patient is allowed to bathe before each inunction if he so desires. Going over the section to be anointed with a little ether, just before applying the ointment, greatly facilitates its absorption. I prefer an ointment composed of very pure oil of sweet almonds, wax, gelatin, soap, and water, containing fifty per cent. of mercury. This preparation contains none of the greasy elements which make the use of the old official "blue ointment" so objectionable to many. It has no odor, keeps well, and its application is accomplished with a few moments of rubbing. On the hands, feet, and face the white mercurial ointment is used, preferably before retiring, when required in the first weeks of the secondaries.

During the first year of the disease, three complete series of inunctions usually suffice to accomplish the best results, no other medication being used in the general treatment. The first series is given daily, while in the second and third, every other day usually works best. The physician should insist upon the inunctions being administered by a competent assistant.

1265 BEDFORD AVENUE.

REPORTS OF TWO CASES OF CURED GRAVES'S DISEASE.*

By GERALD BERTRAM WEBB, M. D.,

COLORADO SPRINGS.

I am reporting briefly the histories of two cases of Graves's disease, cured by a method which I think is somewhat unusual.

I will relate them just as they came to me, and I will give the theoretical ideas I carried into practice, just as they entered my mind.

The treatment of the first case occurred in the year 1900.

Mrs. P., a widow, aged 45 years. Occupation, boarding house keeper. Patient had suffered from Graves's disease for nine months. She had been under numerous physicians, and had tried various treatments and various climates with no improvement.

Family history: Nothing of importance. Later I found a son to be a hemophilic.

History of case: Patient related that the disease had started with feelings of intense heat, a palpitating heart, and insatiable thirst. These symptoms had been followed seven weeks later by the goitre and exophthalmos, the latter being accompanied with burning pain in the eyes.

In her earlier history there was little of importance to note, beyond severe nervous and mental strains, and periodical distressing headaches. These headaches had been absent during the course of disease, but returned when the patient became well.

* Read before the El Paso County Medical Society.

Menstruation was normal, and is so to this day, the patient being now fifty years old.

The patient presented markedly the prominent symptoms of Graves's disease, goitre, exophthalmos, tachycardia, and tremor; many minor ones were also present. She had a singularly alert mind and her memory was exceptionally good, enabling her to memorize with greater ease than either before or since the disease. She was exceedingly restless, irritable, and fidgety.

When I was summoned to attend the patient she was suffering from a most severe, watery lenteric diarrhoea, a dozen movements an hour being by no means unusual. It was impossible to count her pulse, the palpitation of the heart being so great. Her condition seemed critical.

Whilst observing the patient, I was struck by the great waste of nervous energy going on, due to the tremor and jactitation of the extremities. The thought came to me, whilst putting the Graves's disease itself from my mind, that could I stop this leak in the nervous energy reservoir, she might improve. Going further, I revolved the question, why could not the whole disease be due to a neurasthenic condition, in one who had forced herself along with a determined will, when the nervous system had been exhausted and should have been relaxed; it was so evident that many voluntary nerves were acting in an involuntary manner, and involuntary nerves were out of their automatic gear, resulting in disordered functions and the consciousness to the patient of organs not heretofore noticed.

The patient seemed to have lost the power to guide her voluntary nerves, and was obeying every dictate these sent to her.

Knowing that a cardinal part of the cure of neurasthenia depends on a patient controlling her voluntary nervous system first, and that then the automatic or involuntary system will right itself in time, I sat down beside her and proved to her that the tremor was due to a lack of mental control. In a few minutes she was able to exercise the necessary control, and I was able to get her fully relaxed.

Then realizing the too wide awake and active state of her brain, with her mind running in every direction, I selected simple inspiring poems to be memorized. Personal experience had taught me that it was far easier to relax the body than the mind, and that if the brain continued its unchecked, riotous behavior, little good was gained by bodily relaxation. Every day, at certain hours exactly I instructed the patient to recite these poems to herself, and to concentrate her whole being in them. From the first improvement was marked, and in a few weeks she was wonderfully changed. However, it was nearly a year before she was quite herself again. In the light of my second case I cannot but feel that the length of time taken in her cure could have been materially shortened, could I have isolated her from her family and cares.

CASE II.—After a lapse of four years, with no new encounter with Graves's disease, I was consulted in January, 1904, by a second case.

Mrs. Z., a widow, aged 40 years; boarding

house keeper; had suffered from Graves's disease for nine months. She had received advice and treatment from several physicians.

History of case: As in the former, nervous and mental strains had been frequent and severe. All her life she had endured periodic painful headaches. Menstruation was normal and is so to this day. The patient related that in April, 1903, she had experienced a sudden loss of flesh; this was followed two months later by the exophthalmic goitre symptoms. She also had had attacks of severe watery diarrhoea, when her temperature would register 103° . Examination revealed all the chief symptoms of the disease, namely, goitre, exophthalmos, tachycardia, and tremor.

Recalling my former case, I was especially struck with the fidgetiness and tremor, and that the mind was very alert. But this time there was also a condition of absent mindedness, which was characterized by a sudden downward and sideways fixed stare of the eyes, whilst conversing. Again the idea recurred to me, that could I check so much leakage of nervous energy from the reservoir of nervous matter, the Graves's symptoms might disappear with the neurasthenic.

My treatment was very similar to that employed in the first case. A placebo was administered. Absolute relaxation for mind and body was to be methodically carried out. Moderate exercise, cold baths, the cold water to be applied especially to the nape of the neck. Improvement came immediately, but owing to illness in her family, the patient was unable to do justice to the treatment.

After about three months, I isolated her from her family and removed her to a ranch a few miles from town. Here in a few weeks all the remaining symptoms entirely disappeared. In undergoing her cure, the patient's weight increased from 70 pounds to 117 pounds, a gain of 47 pounds.

Finding that piano playing and horseback exercise were pursuits that absorbed the patient, I allowed them in moderation, the latter in spite of the fact that she had been warned by a physician that she might fall dead any minute if she exercised much. The headaches of her earlier history have never returned in so severe a form, and during the course of the disease were entirely absent.

In summing up these two cases you will have noticed many resemblances. Both were in their forties, both were widows, and both were boarding house keepers (at which occupation they are again engaged), consequently both had been severely tossed by the tempests of life. In spite of severe headaches and great restlessness, both had kept to their work, although with their nervous systems almost bankrupt. Neither had reached the climacteric, nor has either yet. I may add that both still retain an unusual aspect of the eyes, a probable sequel to the stretching.

My theory in regard to the origin of Graves's disease in these women is, that it resulted from nervous exhaustion, and that the escape of nerv-

ous energy needed blocking, as proved in both cases by the result of the treatment practised. To help bear out my theory is the fact we all know, that the early diagnosis of Graves's disease from neurasthenia is often impossible.

The treatment, based on the theoretical cause, I have termed a recreation nerve cure. The term "rest cure" I have always felt to be a misnomer, for my best results in the cure of nervous patients have always been brought about by keeping them the busiest people in town. To use a quotation, the author of which I cannot recall:

Lack of occupation is not rest,

A mind unoccupied is a mind distressed.

The choice of diversions for such recreation is of paramount importance, and keeping in mind another quotation,

The pleasures we delight in phisic pain

instruct such patients to occupy themselves in moderation with pastimes which will absorb them body and mind.

Teach method, relaxation, and control. These three will lead to the cure of these patients. While in textbooks of medicine little is known of the cure of a disease, much is written. An instance we can all remember is the disease of diphtheria, on which pages of treatment are now replaced by a few lines. I believe in future this simple method by which I have successfully cured two cases of Graves's disease, will replace the many surgical and medical treatments advocated.

1222-NORTH CASCADE AVENUE.

(In the discussion which followed, Dr. Friedman, an oculist, reported to the society that examination of the eyes of the first case, during the last year, had revealed beginning optic nerve atrophy in each eye.

In reply to questions, the essayist stated that Longfellow's Psalm of Life and Light of Stars were favorite poems selected for patients to memorize.

He considered, too, that the ordinary treatments would of necessity fail because of the attention they attracted to the very organs it was best for the patients to ignore.)

Graduate Nurses from the Massachusetts General Hospital, Boston.—The following young women have received diplomas from this institution.

Edith E. De Land, Nellie J. Harvey, Helen G. Cody, Aletta A. Clark, Olga E. Ahler, Izah Mitchell, Amy O. Gamage, Violet L. Kirke, Justina A. Briggs, Annie C. Carstensen, Catharine Beattie, Olive B. Golding, Mary S. Doherty, Mary E. Smyth, Miriam B. Holder, Maud E. Retallick, Nellie M. Ford, Nellie A. Stevens, Mary R. Walch, Katharine R. Moloney. Those who received diplomas for the thirteen months' postgraduate course were: Hanna R. Hogan, Mabel J. Seaver, Gertrude B. Hislop, Lena B. Tompkins, Mary A. MacNeil, Grace P. Hurlburt, Emma A. Armstrong, Jessie L. Brown.

URÆMIA WITH PERICARDITIS; CLINICAL AND PATHOLOGICAL REPORTS.

By HENRY S. WIEDER, M. D.,

PHILADELPHIA,

AND

HAROLD L. SPRINGER, M. D.,

WILMINGTON, DEL.,

FORMERLY RESIDENT PHYSICIANS OF THE PRESBYTERIAN HOSPITAL OF PHILADELPHIA.

The following is a brief report of the clinical history and the pathological findings of a case of uræmia with pericarditis:

The case of uræmia and pericarditis occurred in a man 50 years of age, stationary engineer by occupation. His mother died probably of alcoholism. He, himself, had had measles, varioloid, mumps, and gout. In July, 1902, he had an attack of gout starting in the great toe of the right foot. He had always been a heavy drinker. This attack of gout confined him to bed for ten weeks, and he stated that from that time he started to decline in strength, although his appetite was good. He would have œdema of the legs for several weeks at a time, easily became dyspnoëic, passed urine frequently, and complained of vertigo.

Physical examination on admission to the hospital: Gouty nose, puffed face, tongue dry and parched, with whitish fur upon it.

Lungs: Expansion very poor. Tactile fremitus decreased over the base of the lungs posteriorly. Breath sounds almost inaudible, and vocal resonance decreased over the base of the lungs posteriorly. Lungs hyperresonant elsewhere.

Heart: Impulse visible in the fifth interspace, palpable in the fourth, fifth, and sixth interspaces, apex sixth interspace one inch within the anterior axillary line. Impulse weak and sharp with slight roughening. The boundaries were hard to determine, but as obtained they were: Upper border in the second interspace, right border one and one half inches to the right of the sternum. The left border passed about one inch above the nipple. On auscultation the first sound was rather quick and of poor muscular tone. At the base the sounds were accentuated and reduplicated. No murmurs were heard, although they had been heard previous to admission.

Liver: Sixth rib to two fingers' breadth below the costal margin.

Epigastrium tender with marked resistance, muscles being very rigid.

Blood: Hæmoglobin 45 per cent. R. B. C., 2,020,000. Leucocytes, 7,000.

A couple of days after admission patient developed pain over the præcordium and a coarse, rasping, superficial friction rub was heard in the fifth interspace to the left of the sternum. It was heard loudest during systole, but partially also during diastole. His temperature rose from 97° to 101° on May 19, 1903, and remained up for two days. He became very restless, could not sleep, and was obstinately constipated. His urine once showed a trace of albumin and on another

occasion was negative; at no time were casts found in a sedimented specimen, although we have since learned that they were found prior to admission in a centrifugated specimen. The urine amounts ran between 64 and 72 fluid ounces.

On the day of his death he became very nervous and said that he feared an attack of delirium tremens. He had considerable pain over his heart, his pulse was poor, and his urine greatly decreased in amount. His condition grew gradually worse until he had a convulsion. He became deeply cyanosed and his pulse very weak. His breathing was stertorous. When he recovered from the convulsion, his pulse gained in volume and he was bled 18 fluid ounces. No paralyzes were present. He continued to get worse, no treatment availing, and he died the same night.

NECROPSY REPORT.

There was no fluid in the abdomen. Relations of the abdominal viscera were normal.

There were 18 ounces of a clear yellow fluid in each pleural cavity. There were no pleural adhesions except at the right apex. In the right apex were several old scars apparently the result of tuberculosis. The bronchial lymph glands were not enlarged.

Pericardium: There was considerable inflammation around the pericardium, the cavity of which contained two ounces of a clear, yellow fluid. The epicardium and the parietal layer of the pericardium were generally adherent, from deposits of fresh fibrin, which covered a large portion of the heart. The fibrin was particularly marked around the great vessels.

Heart: The heart was nearly covered by the left lung which was adherent to the pericardium by fresh adhesions. The left ventricle measured 25 mm. in thickness, was somewhat friable and yellow, and showed some spots of fibrous tissue. The mitral valves were somewhat puckered and the chordæ tendineæ were thick and apparently short. The aortic valve showed a marked degree of atheroma. The three edges of the tricuspid valve were white and puckered, but the orifices of the valve were not contracted. The right ventricle and the right auricle were considerably dilated, and the right ventricle measured 8 mm. in thickness. Weight of the heart, 1,100 gms.

The intestines, adrenals, and pancreas were normal.

The liver was somewhat fatty and pale, but not enlarged.

The stomach showed a moderate degree of hypertrophic gastritis.

Both kidneys were small, especially the left one. They were much scarred. Weight of the right, 120 grammes; left, 90 grammes. The capsules were adherent. There were numerous small cysts throughout the cortex upon section. The cortex was very much contracted.

Pathological Diagnosis.—Hypertrophy and dilatation of the heart. Atheroma of the mitral and tricuspid valves. Acute pericarditis. Fatty and contracted kidneys. Fatty liver.

Cause of Death.—Uremia.

MICROSCOPICAL REPORT.

Kidney: The epithelial cells of the tubules were granular and in some places detached. Many glomeruli were replaced by fibrous tissue and the capsules of Bowman were quite thickened. Cysts were scattered throughout the section varying in size, and the entire organ showed a marked degree of passive congestion.

Liver: This also showed chronic passive congestion to a marked degree and at places fatty degeneration had begun.

Correspondence.

LETTER FROM TORONTO.

Christian Scientists before the Toronto Courts.—The Ontario Board of Health.—Medical Government Officers.—Absentees.—The House Staff of the Toronto General Hospital.

TORONTO, February 18, 1905.

Several Christian Scientists have again been before the Toronto courts. This time the case was that of a young man with typhoid fever and complicating pneumonia at the end. Although the corporation for which this young man worked sent their physician to attend him, he was fast in the clutches of the Christian Scientists, and the medical man was only permitted to see him two or three times. Warnings by him were unheeded, so at last the case was reported to the authorities of the law, and the doctor in question ceased all visits. The police magistrate of Toronto has sent those implicated to be tried before the Assize Court. Another doctor became involved, having been called in just prior to death and issued a certificate of pneumonia. As this was not the first time that the latter physician had issued certificates of death to people dying under Christian Science want of treatment, he came in for some rather sharp criticism in different quarters. We are glad, however, to report that the Toronto Medical Society, of which he is a member, has exonerated him from any unprofessional conduct, considering his action in the light of an error of judgment. No doubt our professional brother will take this seriously to heart and refrain altogether in the future from issuing any more certificates for the Christian Science devotees.

The regular quarterly meeting of the Ontario Board of Health was held in Toronto a short time ago, and from the report of the secretary we gather that there were in the year 1904 25,415 deaths in Ontario, as compared with 25,267 for the previous year, thus giving a rate of 12.8 per 1,000, as against 12.6 in 1903. A noteworthy feature of the report was that the deaths due to preventable causes had decreased by 340, or nearly

10 per cent. This decrease occurred in cases of scarlet fever, which were 400 fewer than for the previous year; diphtheria, 40 fewer; smallpox, 17; whooping cough, 58. Typhoid fever increased by 99 and tuberculosis by 95. The secretary states in his report that the use of antidiphtheritic serum has had no appreciable effect on the death rate from diphtheria, which is higher than in 1903. An effort will be made to have tuberculosis placed on the list of notifiable diseases, as this is a very proper and important step to take in preventing the spread of the disease. The number of deaths from tuberculosis showed an increase from 2,072 in 1903 to 2,168 in 1904. The bacteriologist for the board stated that during the past year a number of patent medicines, foods, and beef extracts had been carefully examined in his department, and in the case of the former a large amount of alcohol had been found, but he had found the foods and beef extracts freer from deleterious ingredients than had been expected. The board has under their consideration the establishment of a bacteriological laboratory at London, Ontario, in connection with the Medical Faculty of the Western University there.

The province of Ontario has recently passed through a general election, and there has been a change of government which, owing to the fact that there are three medical men in the new cabinet, may prove of some value to the medical profession in this Province. Dr. Robert Allan Pyne, who for many years has been the efficient registrar of the Ontario College of Physicians and Surgeons, has been returned for East Toronto by a very large majority and has entered the government as Minister of Education. His duties in connection with this office will be so heavy for some time to come that he will probably relinquish soon the registrarship of the Medical Council. Dr. Réaume, of Windsor, Ont., has also entered the cabinet of the Honorable Mr. Whitney as Minister of Public Works. He will retire altogether from practice. Dr. W. A. Willoughby, of Colborne, is also a cabinet member, but without for the present a portfolio.

The Toronto physicians do not believe in all work and no play. Spring, summer, autumn, or winter, some of them are away enjoying themselves, seeking a short respite from the cares and worries of professional life. At the present time Dr. J. F. W. Ross is in southern California; Dr. George McDonagh is in southern Italy; Dr. W. H. B. Aikins has gone to Vienna; Dr. Breffney O'Reilly is with Dr. Osler in Baltimore; Dr. W. P. Caven is in Atlantic City. Some who have been away and have returned are Dr. Campbell

Meyers, who has been for some months in Europe; Dr. William Oldright, who was at the Havana meeting of the American Public Health Association; and Dr. E. Herbert Adams and Dr. Walter Maybury, who have been investigating the climate of Jamaica.

The eight members of the house staff of the Toronto General Hospital of 1892-'3 recently had a reunion in this city. Those present were the following: Dr. H. B. Anderson, Dr. H. A. Bruce, Dr. Frederick Fenton, and Dr. H. C. Parsons, of Toronto; Dr. J. N. E. Brown, Territorial secretary, of Dawson, Yukon Territory; Dr. Middleboro, of Owen Sound; Dr. A. S. Tilley, of Bowmanville, Ont.; and Dr. H. J. Way, of Chicago. Dr. Charles O'Reilly, the medical superintendent of the hospital, was present, and stated that he was glad to know that four of these had taken English degrees and two the F. R. C. S. by examination since their graduation. Since 1876, when he was appointed superintendent of the hospital, 220 house surgeons had passed under his tuition, and he was very glad to say that but eight of them had gone beyond in the twenty-eight years since that time.

Therapeutical Notes.

Dangers of the Use of Hydrogen Dioxide in Otolology.—Bruder, of Paris, is cited in *Semaine médicale*, for September 25, 1904, as stating that not only may an unpleasant maceration of the tissues of the external ear follow the use of hydrogen dioxide in otological practice, although the instillation of a little oil of petrolatum will prevent this, but that he has seen excessive swelling of cholesteatomata ensue on its application to these growths; so great, indeed, as to produce prohibitive pain and vertigo.

Laurens, of Paris, attributes a death among his patients to the transmission of infection by bubbles of oxygen from the same agent, from the lateral sinus upon which he had operated for phlebitis, to the meninges of the cerebellum. The patient died comatose after suffering from intense headache and high fever.

Treatment of Infantile Syphilis.—Levisaur (*Journal des praticiens*, No. 28, 1904; *Journal of Cutaneous Diseases*, February, 1905) states that infants stand mercurial inunctions very nicely. Two grammes of blue ointment should be rubbed in every morning for five minutes by aid of a piece of flannel. Beginning on the abdomen a different region is selected for each day. This treatment is carried out for one month, then stopped for one week and taken up again after this rest. Local lesions should be dressed with ammoniated mercury salve (10 per cent.). One year of inunctions is followed by the administration of potassium iodide (10 grains, three times a day) for three weeks. Every three months inunctions are again given for two weeks.

NEW YORK, SATURDAY, MARCH 4, 1905.

DR. WILLIAM OSLER ON SENILITY.

On Wednesday of last week, in a valedictory address at the Johns Hopkins University, Baltimore, Dr. Osler, who is soon to take up the work of a professor in the medical faculty of the University of Oxford, England, put forth certain statements which have led to widespread comment, mostly unfavorable, on the part of the newspapers. Some of the reports that have appeared in print have put him in a false light. For example, he has been made to seem to approve of the suggestion that men who have reached the age of sixty—and therefore have in his opinion generally outlived their usefulness and even tend in their further career to prove detrimental to the world's progress—should be put to death with chloroform. It is true that he jocularly mentioned a discussion of this suggestion in a certain book of fiction, but that he was not speaking seriously on this point ought to have been plain from his frequent allusions to his own close approach to the age of sixty. In a telegraphic dispatch to the editor of this journal, dated February 27th, he says: "Contradict emphatically that I advised chloroforming men at sixty. I said that man's best work was done before forty, and at sixty he should retire." In a subsequent com-

munication he says that the whole matter of the chloroforming was a joke.

It is no more than fair to say the foregoing, but there remain very positive expressions of opinion by Dr. Osler, expressions that he stands by. The pith of them is given in the second sentence of his dispatch. We do not believe that he is correct in this matter, and we are quite sure that some of the examples of medical men that he adduced as illustrating the tenability of his position do not bear him out in the least. Among the names mentioned were those of Virchow and Bichat. When we recall the tremendous importance commonly attached to the work done by Virchow up almost to the very end of his long life, we cannot admit that his career illustrates Dr. Osler's belief. As for Bichat, it is true that he did his work while he was young, but he died young, and we shall never know what he might have accomplished had he lived to old age.

But it seems to us that the radical fallacy of Dr. Osler's doctrine is shown by something that he looks upon as confirming it. He holds that up to the age of forty a man should devote himself to acquiring knowledge as to matters of fact, and that not until after that age should he attempt to generalize. Observation, then, according to him, is the proper pursuit of a man at the height of his powers, while deduction is allowable only when he has begun to degenerate; in other words, the acquisition of knowledge calls for mental powers superior to those that suffice for systematizing that knowledge and employing it as a basis for teaching and for the formation of theories. The senses, then, are higher than the intellect. If he holds to such a notion as this, it is no wonder that Dr. Osler chimed in with the threadbare belittling of American medicine because of the small part it has thus far taken in original investigation. There are some of us who think it a higher intellectual function to make the best possible use of recorded observations than to do actual laboratory work. From this point of view and from that of their tendency to discourage middle-aged men, we think that some of Dr. Osler's remarks are to be regretted.

CHEERING WORDS FOR HOME BOUND CONSUMPTIVES.

For nearly four years now a most interesting experiment has been in progress on Ward's Island, in the city of New York, and it may fairly be said to have passed the stage of experiment and become an established feature of practice in the Manhattan State Hospital, East, under the enlightened and progressive management of Dr A. E. Macdonald. It is that of treating the consumptive insane in tents. Dr. Macdonald's account of the experience has been published by the Charity Organization Society, in its *Directory of Institutions and Societies dealing with Tuberculosis in the United States and Canada*, and by the National Association for the Study and Prevention of Tuberculosis. It has now been issued in pamphlet form.

It was at first supposed that the camp treatment would be practicable in the mild season only, but it has been found exceedingly satisfactory to continue it through the entire year. "The Ward's Island camp," says Dr. Macdonald, "is but a few feet above the tide water level, its site is swept in winter by winds of high velocity, coming over the ice bound waters of the rivers and the sound which surround it, and it suffers as much as, or more than, any other part of the city of New York from the trying changes of temperature and humidity which are so characteristic of its climate." And he asks: "If, in spite of all these drawbacks, what has been done can be done, and that for insane patients, what may not be hoped from the extension of the same methods to the ordinary consumptive of sound mind, anxious for recovery, and capable of giving intelligent assistance in the struggle?"

It was feared at the outset that both the patients and their friends would protest against the open air treatment, but such protests have been very few, and, indeed, the cry now is for the early vernal restoration to it of the few who were returned to the buildings for the winter. The effect on the tuberculous trouble has been most gratifying—indeed, in one instance a man's weight was doubled—and both the patients and the nurses in the camps have enjoyed almost complete immunity from other pulmonary disease; not a single case of pneumonia has occurred among them

during the period, and colds have been unknown. In several instances the patients' mental condition has been much ameliorated and in a few wholly restored to the normal.

TUBERCULOUS INSANITY.

The Henry Phipps Institute for the Study, Treatment, and Prevention of Tuberculosis, of Philadelphia, has recently issued its *First Annual Report*, a volume of 265 octavo pages. The report presents an account of the institute's first year of work in its temporary quarters in Pine Street. Very appropriately, the lectures given to the public under the auspices of the institute are appended to the body of the report. The entire contents of the volume abundantly show the utility of the institute from the very day of the opening of its building, and are of exceeding interest to students of tuberculous disease, but we can here notice with any approach to detail only one of the features of Dr. D. J. McCarthy's report on the neurological work, the one in which he deals with the insane conditions met with in the tuberculous.

Peculiar mental states associated with tuberculous disease have excited attention from remote times, but Clouston seems to have been the first to treat of the tuberculous insanities systematically, and certain forms appear to have escaped his observation. Among 1,674 tuberculous subjects, Dr. McCarthy has observed ten who showed insanity. In four instances it was of the parietic type, in two it was set down as dementia præcox, in two it was delusional, and in two it was hysterical. He thinks that the insane states met with in tuberculous disease may be divided into two groups, one peculiar to the disease itself and the other including the usual types of insanity occasioned by a lowered state of nutrition.

A patient with tuberculous disease, says Dr. McCarthy, may know that his case is absolutely hopeless, and yet he may be happy and contented, and this, too, in spite of very decided physical suffering. He is apt to have expansive ideas and distinct delusions of grandeur. Such cases are classed by him as of the parietic type. "Speech," he says, "was tremulous and often distinctly parietic and stuttering in type." He further says: "There was a distinct tremor of the tongue and

of the hands, and in some cases this was so marked as to dominate the clinical picture."

ADENOIDS IN THE NEGRO.

In an article on Hypertrophy of the Pharyngeal Tonsil recently published in one of the medical journals the statement was made that this pathological condition did not exist in the negro race. As I have frequently seen this form of hypertrophy in the nasopharynx of negro patients in the free clinics of our Southern cities, it will be interesting to compare the frequency of adenoids in the negro and in the white race. One of the elements of uncertainty in this comparison is the increasing rarity of the negro as a racial type. In the first place, although there is a popular belief that "all coons look alike," there are as many types of the African negro as there are types of the Caucasian, differing in their physical characteristics as clearly as the French from the German or the Russian from the Italian. In the second place, through intermarriage with lighter races, the negro is losing much of his distinctive type, and more so with each generation.

Some years ago, in an article entitled *The Comparative Pathology of the Negro in Diseases of the Nose, Throat, and Ear, from an Analysis of 11,855 Cases* (*Annals of Ophthalmology and Otolaryngology*, Vol. iv, No. 4), the writer called attention to the comparative immunity of the negro to many diseases of the nose, throat, and ear. In this analysis hypertrophy of the pharyngeal tonsil was found in 982 cases of whites as compared with 219 in the negro, the latter thus forming only 22 per cent. of the total number of cases. In this tabulated list, however, the term "negro" was not limited to the pure African type, on account of the difficulties already referred to, but, approximately speaking, about one fourth of the number were sufficiently black to pass for this type. This would reduce the percentage of adenoids in the negro proper to about $6\frac{1}{2}$ per cent. of the total number of cases of adenoids.

While the white population of New Orleans, where these statistics were made, is about three times as great as the colored, still this is offset by the fact that a much larger percentage of the

negro population takes advantage of the free clinics, so that the foregoing figures give a fairly correct ratio of the proportional frequency of adenoids in the white, and in the negro race living in the Southern States.

In connection with this pathological condition, we must not overlook certain anatomical differences between the whites and the negroes which have an important bearing on this subject. The negro normally has broad, patulous nostrils which render him much less apt to suffer from the effects of a postnasal obstruction than the white. In white children suffering from adenoids there is more or less arrest in the development of the nasal organs, and this, added to the difficulties of the already impeded nasal breathing, soon develops other complications which bring the patient to the attention of the physician. In the negro, however, the roomy nostrils allow fair nasal breathing in spite of a considerable hypertrophy of the pharyngeal tonsil, so that the complications are much less frequent, and the cases are therefore less likely to come under observation.

In this connection, it is interesting to note that, in the cases analyzed in the report already referred to, a deformed nasal septum was ten times, and deaf-mutism sixteen times, as frequent among the white as among the colored patients.

WILLIAM SCHEPPEGRELL.

A CENSORSHIP OF PROPRIETARY REMEDIES.

There was provided at a meeting of the Board of Trustees of the American Medical Association, held on February 3rd, an advisory board to be known as the Council on Pharmacy and Chemistry of the American Medical Association. The object of the formation of this council, as we learn from a circular of information issued by Dr. Simmons, is to establish a kind of censorship over the proprietary preparations, synthetical chemicals, and trade mark specialties offered to the medical profession, and the eventual publication of a list of such remedies as conform to the requirements of this council in a book to bear the title *New and Non-official Remedies*. This book is intended to stand as a supplement to the *Pharmacopæia*, and the latter publication will be followed as regards plan and arrangement. The ten rules which have been formulated for the guidance of the Council on Pharmacy and Chemistry are printed in our news columns, and in so far as

any rule can be formulated for the distinction of objectionable from non-objectionable preparations, these rules seem to us to be quite satisfactory. The composition of the council is one which gives assurance of really expert and sane advice; but even with the best intention and with the most expert administration, the establishment of such a censorship is likely to prove a source of serious contention, and will undoubtedly involve the association in trouble of a kind that it has been heretofore free from.

ORGANOTHERAPY.

The idea of supplying from the healthy organs of animals some deficiency in the secretory organs of man is a very ancient one. Travelers tell us of the custom which prevails among certain tribes of African savages of appropriating the organs of animals possessed of courageous, ferocious, or bloodthirsty attributes, in order to imbue themselves with the peculiar characteristics of the animal selected. It is hardly to be supposed that the alchemists of the Middle Ages proceeded on so empirical a method or were guided by the same sort of intuition possessed by the savages, but the one curiously reflects the other and the resemblance in methods is striking, being almost as great as that between present day organotherapy and the organotherapy of the period of the Renaissance. Mr. Thomas J. Keenan, the associate editor of the *American Druggist*, in a paper read before the Kings County Pharmaceutical Society, and published in the February 27th issue of his journal, instances a number of mediæval preparations of animal origin and points to an interesting contrast between them and the later additions to our modern *materia medica* for which Dr. Brown-Séquard, Dr. W. A. Hammond, and the pharmaceutical manufacturers are responsible. He enumerates a large number of remedies of recent introduction, which consist either of the substance of the internal organs of animals, of the active principles of these, or of synthetic chemical compounds intended to represent them, and his paper forms a valuable contribution to the literature of medicine.

ERGOPHOBIA.

In the *British Medical Journal* for February 11, 1905, W. D. Spanton, F. R. C. S., states that he has coined the word *ergophobia* to express the growing dislike of exertion among British workmen. Our readers will remember that we used this word, believing it to be original, in our issue of October 10, 1903, and were subsequently informed that it had been in use for a quarter of a

century in the hospital reports of a New Jersey institution. The *New York Medical Journal* and *Philadelphia Medical Journal* was, however, the first to print the word.

THE BABY'S BATH TUB.

We wish we could feel at all sure that the manufacturers of babies' bath tubs would amend a senseless feature of their method of construction, namely, that of affixing the handles to the sides of the tubs, which makes it almost impossible to convey a tub filled with water from one room to another without spilling more or less of the contents. The handles ought to be placed at the ends.

News Items.

Society Meetings for the Coming Week:

MONDAY, March 6th.—New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, N. Y., Academy of Medicine; Utica, N. Y., Medical Library Association; Boston Society for Medical Observation; St. Albans, Vt., Medical Association; Providence, R. I., Medical Association (annual); Hartford, Conn., Medical Society; South Pittsburgh, Pa., Medical Society; Chicago Medical Society.

TUESDAY, March 7th.—New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Elmira, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Hudson, N. J., County Medical Society (Jersey City); Androscoggin, Me., County Medical Association; Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

WEDNESDAY, March 8th.—Medical Society of the Borough of the Bronx, New York; New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Society of the Alumni of the City (Charity) Hospital; Society for Medical Progress, New York; Pittsfield, Mass., Medical Association (private); Philadelphia County Medical Society; Lenox Medical and Surgical Society (private).

THURSDAY, March 9th.—New York Academy of Medicine (Section in Pediatrics); New York Academy of Medicine (Section in Otolaryngology); Society of Medical Jurisprudence and State Medicine, New York; Brooklyn Pathological Society; Medical Society of the County of Cayuga, N. Y.; South Boston, Mass., Medical Club (private); Pathological Society of Philadelphia; Church Hill Medical Society of Richmond, Va.

FRIDAY, March 10th.—Yorkville Medical Association, New York (private); Brooklyn Dermatological and Genito-urinary Society (private); German Medical Society of Brooklyn, N. Y.; Medical Society of the Town of Saugerties, N. Y.

SATURDAY, March 11th.—Obstetrical Society of Boston (private).

Change of Address.—Dr. A. P. Grinnell, of Burlington, Vt., to 500 Fifth Avenue. Telephone number, 5335—38th.

NEW YORK.

Flushing Hospital and Dispensary.—It is believed that the three days' fair held in Flushing for the benefit of this institution will enable the promoters to turn over at least \$10,000 to help the hospital.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending February 25, 1905:

	February 25. Cases.	Deaths.	February 18. Cases.	Deaths.
Measles.....	292	5	209	8
Diphtheria and croup.....	258	45	272	47
Scarlet fever.....	261	14	225	20
Smallpox.....	5	1	1	1
Chickenpox.....	121	1	132	1
Tuberculosis.....	318	164	339	171
Typhoid fever.....	28	10	23	4
Cerebrospinal meningitis.....	49	4	40	4
	1,283	288	1,201	291

Manhattan Eye, Ear, and Throat Hospital.

The directors of the Manhattan Eye, Ear, and Throat Hospital have decided to proceed with the building of the costly wing of the institution, recently designed, but the consideration of which was temporarily set aside on account of the expense. Owing, however, to the donation of \$25,000 to the project by Mr. Frank Tilford, one of the directors, the latter have concluded that it will be safe to construct the proposed wing, relying upon the generosity of the public to make up any possible deficiency.

The German Charity Ball, recently held, distributed a surplus of more than \$10,000 among the following charities: German Hospital, \$2,200; St. Mark's Hospital, \$1,400; St. Francis's Hospital, \$1,400; German Polyclinic, \$1,400; German Society, \$1,400; Isabella Home, \$1,100; Wartburg Orphan Asylum, \$1,100; German Ladies' Aid Society, \$1,100; West Side Dispensary, \$1,000.

Orthopædic Dispensary and Hospital.—An appeal has been issued on behalf of this institution for an immediate gift of \$1,400 to enlarge the staff of nurses. It is hoped also to get ten subscribers who will supply \$1,000 a year each for five years to the endowment fund. Other subscriptions to this fund are, however, earnestly solicited. It is hoped, also, that the number of annual subscribers will be largely increased.

The Medical Society of the Borough of the Bronx.—Meetings held the second Wednesday of the month at the Bronxland Hotel, corner of One Hundred and Thirty-fourth Street and Willis Avenue. A stated meeting will be held on Wednesday, March 8th, at 8.15 p. m. Programme: Executive session; scientific session: Presentation of Cases, Reports, Instruments, etc.; papers: The Acid Intoxication Complicating Pregnancy, by Henry McM. Painter, M. D.; The Management of Puerperal Sepsis, by James D. Vorhees, M. D.; The Diagnosis and Treatment of Gastric Ulcer, by Charles H. Nammack, M. D. W. H. Kahrs, M. D., secretary.

Academy of Medicine.—The section in otology will meet on Thursday, March 9th, at 8.15 p. m. Order: Presentation of Cases: Tuberculosis of the Middle Ear in an Infant; Radical Operation: Cure, by L. M. Hurd, M. D.; Demonstration of Charts for Teaching Otology, by F. Whiting, M. D.; Exhibition of a Gland Removed from Surface of Mastoid, Simulating Mastoiditis, by J. F. McKernon, M. D.; Report of an Obscure Case of Deafness, by J. E. Sheppard, M. D.; papers: A

Few Remarks on the Proper Treatment of a Running Ear, by H. A. Alderton, M. D.; A Condensed Report of a Case of Streptococcic Otitis Media, Followed by Mastoiditis; Operation; General Septicæmia; Death, by C. G. Coakley, M. D. Emil Gruening, M. D., chairman; W. H. Haskin, M. D., secretary, 42 East Forty-first Street.

Manhattan State Hospital, West, Ward's Island, Clinics.—A clinic in mental and nervous diseases will be given by Dr. Emmet C. Dent every Friday at 3.30 p. m. during the next few months. The subjects comprise the following: Manic Depressive, Dementia Paralytica, Infection Psychosis, Exhaustion Psychosis, Intoxication Psychosis, Organic Dementia, Paranoia, General Neuroses, Defective Mental Development. Weekly clinics are also held Tuesdays at 2.30 p. m. in Gastrointestinal Diseases, and Thursday at the same hour in Gynecology. Special clinics will be given on Epilepsy by Dr. William H. Thomson; Surgery of the Stomach, by Dr. Robert T. Morris; Diagnosis in Heart Disease, with Clinical Demonstrations of Various Valvular Lesions, American Adaptations of the Nauheim Treatment, Resistance Movements, Baths with Demonstrations, by Dr. Thomas E. Satterthwaite; The Dry Carbonic Acid Bath, Carbonic Acid in Mucous Colic, etc., by Dr. Achilles Rose; Intestinal Irrigation and Its Indications with Suggestions as to Antiseptics, by Dr. Douglas H. Stewart, etc.

PHILADELPHIA.

American Therapeutic Society.—The sixth annual meeting of the American Therapeutic Society will be held in Philadelphia on May 4th, 5th, and 6th. Dr. John V. Shoemaker, of 1519 Walnut Street, is chairman of the committee of arrangements. The headquarters of the society will be at the Bellevue-Stratford Hotel.

Medical Alumni Meet.—The Philadelphia Alumni Society of the medical department of the University of Pennsylvania met at the Bourse on Saturday evening, February 18th, at 8.15. Professor Angelo Heilprin delivered a lecture on his Martinique experiences at the time of the eruption of Mount Pelée. A collation followed the lecture.

Scientific Society Meetings for the Week Ending March 11, 1905.—Monday, March 6th, Philadelphia Academy of Surgery; Biological and Microscopical Section, Academy of Natural Sciences; Society of Normal and Pathological Physiology, University of Pennsylvania. Tuesday, March 7th, Academy of Natural Sciences. Wednesday, March 8th, Philadelphia County Medical Society. Thursday, March 9th, North Branch, Philadelphia County Medical Society; Pathological Society. Friday, March 10th, Northern Medical Association; West Philadelphia Medical Association. Saturday, March 11th, West Philadelphia Branch, Philadelphia County Medical Society.

The Frankford Hospital was organized in the spring and early summer of 1903. It is situated

at the southwest corner of Sellers and Penn Streets, Frankford, in a district without hospital accommodation. The nearest institutions of a like nature are the Episcopal Hospital, three and one half miles south; the Jewish Hospital, three miles west; and St. Mary's Hospital, three miles southeast. According to the first report, which has just been issued, and which covers the activities of the institution for the first fifteen months of its existence, a total of 12,359 patients have been treated in its different departments as follows: surgical wards, 77; medical wards, 27; accident ward, 405; surgical dispensary, 2,066; medical dispensary, 245; eye dispensary, 167; ear, nose, and throat dispensary, 89. The trustees have recently rented a three story brick house near the hospital, which has been fitted up for dispensary work and for a nurses' home. This allows an increase of fourteen beds in the capacity of the hospital. The finances of the institution appear to be in satisfactory condition.

Deaths.—Dr. J. B. Howard Gittings died at his home, 4013 Chestnut Street, on February 9th. Dr. Gittings graduated from the medical department of the University of Pennsylvania in 1863. He had practised in West Philadelphia ever since his graduation. He was a member of the Medical Society of the State of Pennsylvania and of the Philadelphia County Medical Society.

Dr. Frank Cowan died in Greensburg, Pa., on February 12th, aged 61 years. Dr. Cowan had been an extensive traveler, having encircled the globe twice during the '80's.

Dr. Alexander Ramsay died at his home, 103 East Lehigh Avenue, of pneumonia on February 12th. Dr. Ramsay graduated from the Medical-Chirurgical College in 1893. He was a member of the Medical Society of the State of Pennsylvania and of the Philadelphia County Medical Society. Dr. Ramsay was 54 years of age.

Dr. John Ruddolph Frailey, a dentist, died at his home, 5138 Lancaster Avenue, on February 21st, aged 72 years.

Dr. Alonzo I. Hunt, of Hamilton Square, N. J., died from pneumonia on February 13th, aged 34 years. Dr. Hunt graduated from the medical department of the University of Pennsylvania in 1894.

Charitable Bequests.—By the will of Mary C. Dulles, who died on January 30, 1904, the Presbyterian Hospital receives \$2,000 for improvements to the Margaret Welsh Dulles Memorial. The Presbyterian Orphanage receives \$2,500; the Children's Seashore Home at Atlantic City, N. J., receives \$1,000, and the Day Nursery receives \$1,000.

By the will of Dundas F. Pratt the bulk of his estate, valued at \$77,000, is devised to the Hayes Mechanics' Home.

By the will of Ellen K. Mitchell the Pennsylvania Hospital receives \$5,000 to endow a free bed. The bed is endowed in memory of Major David Lennox, his wife, Lacy Lukens, and their niece, Sarah Lukens.

By the will of Isaac Roskam the following bequests are made: Jewish Hospital Association, \$5,000 for a free bed in the name of Isaac Ros-

kam; United Hebrew Charities, \$2,500; Jewish Foster Home and Orphan Asylum, \$2,000; National Jewish Hospital for Consumptives, Denver, Col., \$2,000; Home for Hebrew Orphans, \$500; Free Hospital for Poor Consumptives, White Haven, \$1,000; Pennsylvania Society to Protect Children from Cruelty, \$500.

Statistics of the Bureau of Health.—During January, 1905, the division of medical inspection of the bureau of health made 2,932 inspections, exclusive of schools, and ordered 536 fumigations. Ninety-seven cases were submitted to special diagnosis. Five thousand one hundred and fifty-four visits were made to schools and 1,111 children were excluded. Seven hundred and sixty-eight cultures were taken; 123 injections of antitoxine given, and 1,551 vaccinations done. In the division of milk inspection 3,809 inspections are recorded, affecting 103,140 quarts of milk, of which 342 quarts were condensed. One hundred and twenty-seven chemical examinations were made and 238 microscopic examinations. In the bacteriological laboratory 2,295 diphtheria cultures were examined, 346 specimens of blood for the serum diagnosis of typhoid fever, 240 specimens of milk, 112 specimens of sputum were examined, and 1,676 bottles of antitoxine were supplied. The following is the census of the Municipal Hospital:

	Remaining from December.	Received.	Discharged.	Died.	Re- maining.
Diphtheria	54	101	72	18	65
Scarlet fever.....	113	44	30	5	122
Smallpox	3	0	2	0	1
Other diseases....	0	1	0	1	0

The Health of the City.—The following cases of transmissible diseases were reported to the Bureau of Health for the week ending February 18, 1905:

	Cases.	Deaths.
Typhoid fever.....	98	13
Scarlet fever.....	37	6
Chickenpox	65	0
Diphtheria	89	11
Cerebrospinal meningitis.....	1	0
Measles	21	2
Whooping cough.....	8	4
Tuberculosis of the lungs.....	38	63
Pneumonia	113	102
Erysipelas	11	0

The total death rate for the week was 599, in an estimated population of 1,438,318, corresponding to an annual death rate of 21.66 per 1,000 population. The total infant mortality was 100; under one year, 77; between one and two years, 23. There were 36 still births; 26 males and 10 females. The following deaths were reported from other transmissible diseases: Tuberculosis other than tuberculosis of the lungs, 8; dysentery, 2; diarrhoea and enteritis under two years, 6. The temperatures have been low, varying from a minimum of 6° on the 14th and 16th to a maximum of 43° on the 12th. On the 13th the temperature dropped from 34° at 8 a. m. to 18° at 8 p. m., and at 8 a. m. on the 14th the thermometer registered 7°. Many cases of injury from falls on icy pavements were treated in the city hospitals.

GENERAL.

The Presbyterian Hospital, of Chicago, has received the sum of \$15,000 through the will of the late Harriet A. Jones.

St. John's Riverside Hospital, Yonkers, N. Y.—This institution has received \$5,000 through the will of the late Congressman Norton P. Otis.

To Dr. Arnold Stedman, of Denver, a dinner was tendered by his fellow practitioners of that city on February 23rd in honor of Dr. Stedman's birthday.

The Ulster County, N. Y., Medical Association.—At a meeting of this organization on February 20th the following officers were elected: President, J. L. Preston; vice-president, Frederick Hühne; secretary, Mary Gage Day; treasurer, Alice Divine, of Ellenville.

Frances E. Willard National Temperance Hospital, Chicago.—This "temperance" hospital has recently erected a new building to accommodate seventy-five patients. Its various wards have been furnished by individuals in the branch societies of the W. C. T. U.

Phipps Dispensary, Baltimore.—The new tuberculosis dispensary of Johns Hopkins Hospital, for which Henry Phipps, of Pittsburgh, gave \$20,000, was formally opened on February 21st, Dr. H. M. Biggs, of New York, making the opening address in which he spoke of the coming loss to Baltimore of Dr. Osler.

Precautions to Be Taken During the Inauguration Ceremonies.—The authorities of the hospitals of Washington, D. C., have arranged for a special ambulance service and have taken other precautions against the accidents that are supposed to be inseparable from the ceremonies attending the Presidential inauguration, which takes place to-day.

Typhoid Fever in England.—It is stated that an epidemic of typhoid fever in Lincoln, Eng., has already involved over six hundred cases, and the business in the town is entirely suspended. In addition to the Lincoln Hospital, four auxiliary hospitals have been created in the halls of the city, providing 340 beds in all. The mayor has opened a fund for relief and has called for doctors from all over England. The London County Council has sent experts to combat the disease.

A Censorship of Proprietary Remedies.—A Council on Pharmacy and Chemistry of the American Medical Association has been formed, which is to publish a list of the various medicinal preparations offered to physicians, which are not included in the United States Pharmacopœia, or other standard text books or formularies. This council will act under the following rules governing the admission to the proposed book of reference, which is to be known by the title *New and Non-official Remedies*:

RULE 1.—No article shall be admitted unless its active medicinal ingredients and the amounts of such ingredients in a given quantity of the article are furnished for publication. (Sufficient information should be supplied to permit the council to verify the statements made regarding the article and to determine its status from time to time.)

RULE 2.—No chemical compound will be admitted unless information is furnished regarding test, identity, purity, and strength, and, if a synthetic compound, a rational formula.

RULE 3.—No article that is advertised to the public will be admitted; but this rule will not apply to disinfectants, cosmetics, foods, and mineral waters, except when advertised in an objectionable manner.

RULE 4.—No article will be admitted whose label, package, or circular, accompanying the package, contains the names of diseases, in the treatment of which the article is indicated. The therapeutical indications, properties, and doses may be stated. (This rule does not apply to vaccines and antitoxins, nor to advertising in medical journals, nor to literature distributed solely to physicians.)

RULE 5.—No article will be admitted or retained about which the manufacturer, or his agents, make false or misleading statements regarding the country of origin, raw material from which made, method of collection or preparation.

RULE 6.—No article will be admitted or retained about whose therapeutic value the manufacturer, or his agents, make unwarranted, exaggerated, or misleading statements.

RULE 7.—Labels on articles containing "heroic" or "poisonous" substances, should show the amounts of such ingredients in a given quantity of the product.

RULE 8.—Every article should have a name, or title, indicative of its chemical composition, or pharmaceutical character, in addition to its trade name, when such trade name is not sufficiently descriptive.

RULE 9.—If the name of an article is registered, or the label copyrighted, the date of registration should be furnished the council.

RULE 10.—If the article is patented—either process or product—the number and date of such patent or patents should be furnished. If patented in other countries, the name of each country in which patent is held should be supplied, together with the name under which the article is there registered.

This council, which was created at the meeting of the Board of Trustees, held February 3rd, was organized at a meeting held at Pittsburgh, February 11th, and has issued a circular to the manufacturing pharmacists and chemists of the United States and others concerned, dated February 28th, from which the foregoing facts are drawn. Following is a list of the members of the council:

Dr. Arthur R. Cushny, professor of pharmacology in the Department of Medicine and Surgery of the University of Michigan, and recently called to the professorship of pharmacology in the Medical Department of University College, London; Mr. C. Lewis Diehl, professor of pharmacy in the Louisville (Ky.) College of Pharmacy, vice-chairman of the Committee on Revision of the United States Pharmacopœia, chairman of the Committee of Revision of the National Formulary, and for twenty-eight years reporter of the progress of pharmacy for the American Pharmaceutical Association; Dr. C. S. N. Hallberg, professor of pharmacy in the University of Illinois School of Pharmacy, member of the Committee of Revision of the United States Pharmacopœia, member of the Committee on Revision of the National Formulary, and for five years secretary of the Section on Pharmacology of the American Medical Association; Dr. Robert A. Hatcher, professor of pharmacology in Cornell University Medical School, and joint author of *A Text Book of Materia Medica*, by Hatcher and Sollmann; Dr. Lyman F. Kebler, chief of the drug laboratory of the Department of Agriculture at Washington, D. C.; Dr. J. H. Long, professor of chemistry in Northwestern University Medical School; Dr. Frederick G. Novy, professor of hygiene and physiological chemistry in the Department of Medicine and Surgery of the University of Michigan; Dr. William A. Puckner, professor of chemistry in the University of Illinois School of Pharmacy; Dr. Samuel P. Sadler, professor of chemistry in the Philadelphia College of Pharmacy, author of *A Text Book on Chemistry*, associate editor of the United States Dispensatory, and member of the Committee of Revision of the United States Pharmacopœia; Dr. Julius O. Schlatterbeck, professor of pharmacognosy in the University of Michigan School of Pharmacy; Dr. Torald Sollmann, professor of pharmacology in Western Reserve University; Dr. Julius Steiglitz, associate professor of chemistry in the University of Chicago, and the author of several works on chemistry; Mr. Martin I. Wilbert, apothecary to the German Hospital of Philadelphia; and Dr. H. W. Wiley, chief of the Bureau of Chemistry of the Department of Agriculture, Washington, D. C.

Mortality of Michigan During January, 1905.—The total number of deaths reported to the Department of State for the month of January was 3,084, corresponding to a death rate of 14.2 per 1,000 population. This rate is higher than that for the preceding month, which was 13.0 per 1,000, but lower than that for January, 1904, which was 14.7 per 1,000. By ages, there were 573 deaths of infants under one year of age; 181 deaths of children aged one to four years, and 960 deaths of elderly persons aged 65 years and over. Important causes of deaths were as follows: Tuberculosis of lungs, 188; other forms of tuberculosis, 34; typhoid fever, 37; diphtheria and croup, 56; scarlet fever, 16; measles, 14; whooping cough, 3; pneumonia, 352; diarrhoeal diseases of infants under two years of age, 54; meningitis, 38; influenza, 120; cancer, 142; accidents and violence, 139. There was an unusually large number of deaths from smallpox during the month, distributed as follows: One in Battle Creek City, Calhoun county; two in Hillsdale City, Hillsdale county; five in Jackson City, and two in Columbia township, Jackson county.

A Dettweiler Foundation.—To honor the memory and the works of the late Geheimrath Dr. Peter Dettweiler, the founder of the Falkenstein Sanatorium and the first people's sanatorium at Ruppertsheim, it has been decided, by his friends, admirers, patients, and pupils, to establish an institution bearing his name, which shall be a home for physicians who have served in sanatoria for consumptives, and who have become invalidated by disease, accident, or old age. For the collection of funds and the final arrangements a committee has been formed under the patronage of H. R. H., the Princess Friedrich Carl of Hesse. This committee is composed of many of the foremost men and women of the German empire. Of the medical men who have signed the appeal for funds we read such names as Besold, the successor to Dettweiler; Professor Kurschmann, of Leipzig; Professor Flügge, of Breslau; Professor B. Fränkel, Professor von Leyden, and Professor Pannwitz, of Berlin; General Dr. von Leuthold, physician to the Emperor; Professor Schmidt, of Frankfurt, etc. Contributions are to be addressed to Grunelius and Company, bankers, 16 Gr. Galus Strasse, Frankfurt on the Main.

National Convention of American Medical Association at the Lewis and Clark Exposition.—The greatest gathering of medical men ever held west of the Rocky Mountains will be that during the Lewis and Clark Exposition at Portland, Ore., this summer, when the American Medical Association will meet in convention. It is expected that at least 2,500 doctors will attend, and that these will bring with them their wives, families, and guests, to the number of 5,000 more. The sessions of the association will be held from July 11th to July 14th, inclusive. Dr. K. A. J. Mackenzie and other physicians have organized the work of preparing for the visitors and the plans already formed provide for a number of most attractive features. Social entertainments will be on a large and elaborate scale. Trips up and down the Columbia River, where the scenery rivals any

in the world, are among these. To enable delegates to appreciate thoroughly the river scenery it has been arranged to hold one day's session on barges, which will be hauled by steamers down the Willamette River, a distance of eleven miles, to the Columbia, and then for a considerable distance up that world famous stream. Facilities for such an excursion are of the best, the river steamers being powerful and safe and the barges fitted with every arrangement for the comfort of tourists. The general sessions of the body will be held at the exposition grounds, in Festival Hall, a building erected especially for such purposes, and other meetings will be held at various places throughout the city. The various sections of the association—medical, gynaecology, surgery and anatomy, obstetrics, ophthalmology, diseases of children, nervous and mental diseases, cutaneous medicine and surgery, laryngology and otology, materia medica, pharmacy and therapeutics, pathology and physiology—will be provided with suitable separate accommodations. A special meeting place will be furnished house delegates, consisting of 100 or more members, who will transact the business affairs of the body. Arrangements are being made for rooms and board for the visiting medical men, and no difficulty is anticipated in securing suitable accommodations. Portland is amply provided with scores of first class hotels and hundreds of family boarding houses. Besides these the houses of Portlanders will be thrown open for the accommodation of visitors. A hotel within the grounds will accommodate 600. The railroad companies are lending assistance to the Lewis and Clark Fair project with an enthusiasm that has not characterized their attitude toward earlier expositions, and have provided lower rates from distant points than were ever before offered for a similar event. Under the schedule already made out, a person living in the Mississippi Valley may come to Portland and return for \$45. The rate for the round trip is \$52.50 from St. Louis and \$56.50 from Chicago, and one fare from points farther east. The tickets sold will be good for ninety days, and will provide almost unlimited stop-over privileges.

Obituary Notes.—Dr. E. C. O'Brien, one of the best known physicians in Buffalo, died February 26th, aged 65 years. He graduated from the medical department of the University of Buffalo in 1867, and served later as curator of the university. Dr. O'Brien served five times as health physician of Buffalo, and was nominated by President Cleveland as health officer of the port of New York, but failed of confirmation.

Dr. George Lederman Hyslop, a graduate of the medical department of New York University of 1850, died at his home, 153 East Forty-sixth Street, on February 25th, after a four days' illness of heart disease. He was 79 years old, and had practised in New York for fifty-four years. Four years ago he retired from practice. Dr. Hyslop was a founder of Demilt Dispensary, and during the cholera epidemic in New York in 1849 served as a volunteer at the cholera hospital.

Dr. Elihu Russell Houghton died in New York on February 20th. He was a graduate of Am-

herst College, and received his degree of M. D. from Bellevue Hospital Medical College in 1888. He had served in the navy, immigration service, and Marine Hospital Service.

Dr. Mortimer W. Shaw, of 118 Cedar Street, New York, died in Middletown, N. Y., on February 22nd, of pneumonia, aged 37 years. He graduated from Long Island College Hospital in 1892.

Dr. William E. Griffiths, who died in Brooklyn on February 20th, served throughout the Civil War on the U. S. S. *Colorado*. He took his medical course in the College of Physicians and Surgeons, of New York, graduating in 1868, and for more than thirty years practised in Brooklyn. During the Franco-Prussian war he was studying in Berlin, and spent some time in the ambulance service of the Bavarian army. Dr. Griffiths was visiting surgeon to St. Mary's Hospital, was for several years on the board of health and was a member of several medical societies and clubs. He was 63 years old.

Dr. John Stafford, one of the oldest physicians in the country, died in Rochester, N. Y., February 24th. Had he lived, he would have been 100 years old on March 15th. Dr. Stafford was a native of Manchester, Ontario County, and graduated from Hobart College. He studied medicine with a physician and was licensed to practice by the board of censors. He practised in Manchester until 1875, when he removed to Rochester.

Dr. John H. Claiborne, a widely known Southern physician, died in Petersburg, Va., on February 24th, after a brief illness. During the occupancy of Petersburg by Lee's troops in 1864, Dr. Claiborne was senior surgeon to the hospitals in the city. He was a fellow of the Southern Surgical and Gynecological Association, of the American Medical Association, a fellow of the American Health Association, and of the Boston Gynecological Association, and a fellow elect of Victoria Institute of Great Britain.

Dr. E. S. Freed, of Chambersburg, Pa., committed suicide in his office on February 27th by shooting.

Dr. John W. Lawson, former Congressman from the Second Virginia District, died at his home in Smithfield, Va., February 21, aged 68 years. Dr. Lawson was chairman of the board of visitors of the College of William and Mary, and was president of the Smithfield female institute.

Dr. James E. Crisfield, of Dansville, N. Y., died in Jacksonville, Fla., February 21. He was the oldest practising physician in Livingston County, and had been prominent in political circles.

Dr. Israel T. Hunt, a well known Boston physician, fell from a window in his home, February 16th, and was dead when found. His grandfather was Israel Hunt, who was prominent at the battle of Bunker Hill. Dr. Hunt was a surgeon during the Civil War, and for many years past had been prominent as an insurance examiner. He was 65 years old.

Dr. Spencer Van Dalsen died at his home in Paterson, N. J., February 16th, of pneumonia, aged 52 years. He graduated from the College of Physicians and Surgeons, New York, in 1876.

Statement of Mortality in Chicago for the Week Ending February 25, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's estimated midyear populations of 1,990,750 for 1905, and of 1,932,315 for 1904:

	Feb. 25, 1905	Feb. 18, 1905	Feb. 27, 1904
Total deaths, all causes.....	637	630	674
Annual death rate per 1,000.....	16.73	16.50	18.24
By sexes.....			
Males.....	377	351	364
Females.....	260	279	310
By ages.....			
Under 1 year.....	168	149	109
Between 1 and 5 years.....	75	64	64
Over 60 years.....	122	116	171
Principal causes of death.....			
Acute intestinal diseases.....	30	25	28
Apoplexy.....	14	15	17
Bright's disease.....	28	36	37
Bronchitis.....	41	35	37
Consumption.....	71	73	79
Cancer.....	23	21	32
Convulsions.....	19	20	11
Diphtheria.....	8	6	5
Heart diseases.....	36	45	60
Influenza.....	10	8	9
Measles.....	3	1	0
Nervous diseases.....	31	27	21
Pneumonia.....	135	136	151
Scarlet fever.....	0	3	9
Smallpox.....	2	4	0
Suicide.....	4	10	10
Typhoid fever.....	2	2	10
Violence (other than suicide).....	18	24	36
Whooping cough.....	7	3	0
All other causes.....	151	136	132

Although seven more deaths were reported during the week than during the week of the 18th the indications of the state of Chicago's health are more reassuring than at any time since last November. During the last four weeks there have been 2,351 deaths from all causes reported and the annual mortality rate is 15.40 per 1,000 of population. During the corresponding four weeks last year there were 2,522 deaths, or 171 more, reported, and the annual mortality rate was 17.46, or 11.7 per cent. higher. One of the principal causes of this reduction is the lesser prevalence and fatality of pneumonia this winter than last. In the first 56 days of last year there were 1,151 deaths from pneumonia; during the corresponding period this year there have been 1,019, or 132 fewer. On the other hand, there have been 39 more deaths from consumption, and the ratio of consumption deaths (551) to deaths from all causes (4,838) has increased since the first of the year to 11.3 per cent. as compared with 10.4 per cent. last year. The following comparative statement of consumption and pneumonia mortality in Chicago and in New York is an extension of the table in the Bulletin of January 28th. The period covered is between October 1, 1904, and February 25, 1905:

Total deaths.	Consumption.	CHICAGO. Per cent.	Pneumonia.	Per cent.
10,723	1,226	11.4	1,819	16.9
28,774	3,302	NEW YORK. 11.4	5,016	17.4

The population of Chicago for 1905, as computed by the United States Census Bureau, is 1,990,750. The estimated population of New York is 3,945,191, or not quite twice that of Chicago. Multiplying by two Chicago's figures of total deaths, deaths from consumption, and deaths from pneumonia shows excesses of 7,328 total deaths, 850 consumption deaths and 1,378 pneumonia deaths for New York over Chicago.

Pith of Current Literature

FORTSCHRITTE DER MEDIZIN.

December 1, 1904.

1. Rapid Dilatation of the Cervix with Bossi's Dilator,
By EHRLICH.
2. Puerperal Thrombosis with Embolism. Pulmonary Dis-
ease in Puerperal Women, By RICHTER.

1. **The Rapid Dilatation of the Cervix With Bossi's Dilator.**—Ehrlich discusses the advantages and disadvantages of this powerful instrument. He thinks the objections to its use are often founded upon misunderstanding and misapprehension as to its value. He reports 30 cases in which it has been used with advantage. The most important indications for its employment are eclampsia, fever during labor, tetanus of the uterus, deferred delivery in consequence of contracted pelvis, premature separation of the normally implanted placenta, and induced labor in consequence of contracted pelvis. Labor was repeatedly induced by means of this instrument, in Leopold's clinic, easily and without danger. An urgent indication for interference on account of possible danger to the pelvis of the mother or the child is a condition which must be present in order to justify its use. Such a condition is of greater significance than the period of pregnancy which may have been reached, or than the question as to whether the patient is a primipara or a multipara. Leopold has never seen any serious injury to the cervix from its use whether the cervix was shortened or whether it retained its ordinary outline. In the latter condition, however, this dilator must not be used unless the indications are imperative. If patience is exercised in producing dilatation with this instrument, and Bossi's directions for its use are carefully followed, there will probably be no more extensive injury to the uterus than would happen in any case of operative interference for the termination of labor. Operation by means of the forceps is preferable to turning and extraction after this instrument has been used. This instrument certainly marks an advance in obstetric art, at least for private practice, while the vaginal Cæsarean section, symphyseotomy, or deep incisions of the cervix may still be preferable for hospital practice.

2. **Puerperal Thrombosis and Embolism.**—Richter has investigated the clinical history of 16,000 puerperal cases in Leopold's clinic, finding as a result 20 cases in which there was embolism, 78 of thrombosis, and 18 of puerperal pulmonary disease. A fatal result attended 60 per cent. of the cases of embolism, this result occurring almost always with the first attack. Inasmuch as embolism can be prevented in many instances, it is very important to have some guiding symptom which may excite suspicion of impending embolism when thrombosis is present. Such a sign is to be found in the increased pulse rate to which attention was called by Mahler, and which Richter found of positive significance in 63 per cent. of cases, while in 34 per cent. it was

not of positive value on account of coexisting fever. In the cases of pulmonary embolism it was a determining factor in 42 per cent. of the cases, and lacked significance in 52 per cent. The increased pulse rate is of greater determining importance in thrombosis than increase in the temperature, or hyperæmia in the loin and in the abdominal wall, or than pains in the hips and sides, all of which have been mentioned by writers as significant. The increase in the pulse rate indicates that on account of the closure of the veins by thrombosis and the necessity for a free collateral circulation there is increased antagonism to the heart action. It also indicates that with the degeneration of the heart which is common among puerperal women the increase of work which is imposed upon the heart can only be compensated by more frequent contractions. The ordinary opinion that there is greater danger from thrombosis of the pelvic veins than from thrombosis of the veins in the lower extremities is believed to be incorrect, and that on the contrary the latter is the more dangerous for larger thrombi are more likely to be separated in the latter condition and produce a fatal result. In the veins of the pelvis only small thrombi are usually liberated. The small emboli which may be liberated in the lungs give rise to symptoms which may indicate irritation of the pleura, pneumonia, bronchitis, or infarcts. When thrombosis is suspected the proper prophylactic measures will consist in absolute rest, bandaging of the varicose extremities, and careful nursing.

December 20, 1904.

1. Serum Treatment of Puerperal Fever, By BUMM.
2. The Theory of Pernicious Anæmia,
By LITTEN and MICHAELIS.
3. The Diagnosis of Pregnancy During Its First Half,
By SARWEY.
4. Spinal Analgesia in Gynæcology and Obstetrics,
By STOLZ.
5. Lumbar Puncture in Eclampsia, By KROENIG.

1. **The Serum Treatment in Puerperal Fever.**—Bumm remarks that no serum has as yet been produced which causes any apparent result in cases in which the disease has invaded the tissues which are beyond those which were the original seat of the infection. On the other hand, he thinks there is no doubt of the efficiency of serum for cases in which the streptococci have not passed beyond the endometrium. He thinks this is also true even if the streptococci have invaded the blood, provided they have not also produced lesions and formed foci for development in the organs. Experiments upon animals have shown that the prospects of recovery become more encouraging the earlier the injection is made after the reception of the infectious material. The dosage should be regulated by the severity of the infection, the size of the patient (animal), and by the time that has elapsed since the infection was communicated. Bumm prefers the subcutaneous use of the serum, in large doses, to its intravenous injection. He administers it at the conclusion of severe labors, if there is disease of the placenta, if there is decomposition of the liquor amnii, and

if fever has been present during labor. He reports an experience of nine cases in which the serum was injected. In all of these there was a decided fall in the temperature, and an increase in the polynuclear leucocytes in the serous discharge from the uterus, this being interpreted as an indication of improvement in the patient's condition.

2. **The Theory of Pernicious Anæmia.**—Litten and Michaelis have deduced the following as the result of a series of experiments which they performed: 1. The serum of pernicious anæmia has neither an agglutinating nor a solvent action upon the blood corpuscles of the patient, either in the body or in a test tube. 2. Neither does the serum show any solvent action upon the blood corpuscles when the Landsteiner method is employed. 3. This want of ability to dissolve the blood corpuscles of the blood of which a given specimen of serum forms a part does not depend upon the absence of the so called complement. 4. The serum of pernicious anæmia also fails to dissolve the blood corpuscles in other specimens of blood, of which it does not form a part, but it does have an agglutinating effect in many such cases. 5. This last mentioned peculiarity is not entirely characteristic, however, of the blood of pernicious anæmia. 6. The inability of the serum to dissolve the corpuscles in blood of which it does not form a part is not due to a want of complement. The authors conclude that it has not been proved, up to the present time, that the blood poison which is supposed to be present in pernicious anæmia is a complex hæmolyisin in the sense in which it has been described by Bordet and Ehrlich.

3. **The Diagnosis of Pregnancy During Its First Half.**—Sarwey recalls the usual signs of pregnancy, cessation of the menses, enlargement and boggy consistency of the uterus, pigmentation, colostrum, etc. But these, or a portion of them, are often wanting, especially in multiparæ. Even the sound of the foetal movements which, according to Olshausen, can be heard at the end of the fourth month frequently fails to be appreciated by the ear of the listener. The author desires to add to these signs one which he has found of great assistance, namely, the foetal heart sounds which he has been able to distinguish as early as the thirteenth week of pregnancy. In a series of ten cases which were examined between the thirteenth and eighteenth weeks of pregnancy he did not fail to find the foetal heart sounds in a single instance. These sounds change their position very frequently, hence it may be necessary to search for them over the entire area of the uterus. They are most readily determined, as a rule, in the vicinity of the lower uterine segment. A sensitive ear, absolute quiet on the part of the patient, and patience on the part of the examiner are indispensable conditions to the detection of the foetal sounds. Their volume will also be more or less regulated, as a matter of course, by the conductivity of the tissues between the examiner's ear and the foetal heart.

5. **Lumbar Puncture in Eclampsia.**—Krönig

observes that so long as the pathogenesis of eclampsia remains obscure the repeated analysis of its symptoms becomes justifiable. The enormously high blood pressure during eclampsia makes the supposition of high pressure of the cerebrospinal fluid in the subarachnoid space extremely probable. The question which the author proposed was whether the removal of a sufficient quantity of this fluid and the consequent reduction of pressure would have a therapeutic effect. Three cases of eclampsia were treated by lumbar puncture, the blood pressure in each being more than four times the normal. The quantity of fluid removed was 37.5 centimetres in one case and more than this in the others, the blood then resuming its normal pressure. Whether this was the means of cure in these cases cannot be stated with certainty, since in two of them the vaginal Cæsarean section was also performed.

GAZZETTA DEGLI OSPEDALI E DELLE CLINICHE.

January 22, 1905.

1. The Importance of Concealed Hæmorrhages in the Digestive Canal,
By ETTORE TEDESCHI.
2. Unilateral Isolated Paralysis of the Oculomotors in Syphilis,
By G. FAZIO.
3. Contribution to the Treatment of Angular Ankylosis of the Knee by Gordon Buck's Method,
By MATTEO GAPUANO.
4. A Case of Cachectic Aphthæ Treated with Antidiphtheritic Serum,
By FRANCESCO ZUCCALA.
5. The Medical Treatment of Lateral Onychia,
By ALBERTO GASPARINI.

1. **"Occult" Intestinal Hæmorrhages.**—Tedeschi emphasizes the clinical importance of the hæmorrhages which may occur in the digestive tract without being manifest either in the gastric contents or in the fæces, and which have been styled "occult" or "concealed" hæmorrhages by Boas. In order to detect such hæmorrhages it is essential to examine the stomach contents and the fæces for traces of blood or blood pigment. The examination of the fæces is the more important of the two, and yet it is most often neglected, because heretofore we have not had a good way of detecting small amounts of blood. The author describes the following method which he has worked out for this purpose, and in which he employs chiefly the suggestion given by Rossel and by Weber, but with modifications of his own. From 20 to 25 c.c. of pulpaceous fæces are taken and to this sample from 15 to 20 c.c. of neutral ether are added. The mixture is shaken gently and repeatedly in order to remove the bulk of the fat, avoiding the formation of an emulsion which might interfere with subsequent steps. To the fæces are then added from five to seven c.c. of acetic acid, the mixture is shaken, and some more ether is added; the mixture is again shaken and allowed to stand. To the acetic ether extract a few drops of oil of turpentine (old) are added, together with a few drops of freshly prepared tincture of guaiac. A pinch of recently triturated guaiac resin is also added; the mixture is gently shaken in a test tube, and allowed to stand. A violet blue color will appear

if blood pigments are present. Aloin may also be used in this test instead of guaiac, and in that case a 70 per cent. solution of aloin in alcohol is prepared and fifteen drops of it are added to the acetic ether extract after the turpentine has been added. The presence of blood will then be manifested by a cherry color. If there is no blood the color is at first red, but changes to yellow. The aloin test is more delicate and simpler than the guaiac test. The diet of the patient should be looked after, before the test, as an ingestion of two hundred grammes of rare beef (steak) will give a positive test. The administration of iron also gives a positive result. The author found that it is necessary to take from ten to fifteen c.c. of blood into the stomach in order to produce the color reaction described. The new test will be of importance in latent cancer of the stomach, in ulcer of the stomach appearing masked as a simple anæmia, in ankylostomiasis, etc.

3. Ankylosis of the Knee.—Gapuano prefers Gordon Buck's osteotomy to all other methods of treating osseous ankylosis of the knee. In fibrous ankyloses of this joint, gradual reduction of the deformity by means of apparatus is tedious, painful, and untrustworthy. The best treatment for such cases is forcible reduction under anæsthesia. In cases in which chloroform cannot be given, gradual reduction by apparatus may be tried as a last resort. Forcible reduction under narcosis is assisted greatly by tenotomy of the tendons around the popliteal space. This tenotomy is best done "in the open," and not subcutaneously, as thus we are best able to avoid the external popliteal nerve. Osteotomy, according to Rhea Barton, has the advantage of leaving the epiphyses intact, and thus not interfering with the growth of the limb; but, on the other hand, it is apt to be followed by relapses of the deformity. The best method is that of Gordon Buck, which makes a straight and solid limb, but, of course, the epiphyseal cartilages must be carefully preserved in performing this operation in young subjects. It is the method of election in cases complicated with fistulæ and abscesses.

4. "Cachectic Aphtha" Cured With Diphtheria Antitoxine.—Zuccala describes a case of "cachectic aphtha" in an infant, in which he was able to effect a rapid cure, after all else had failed, by the injection of diphtheria antitoxine in a single dose of one thousand units. By "cachectic aphtha" he means the growth on the frenum of the tongue which appears in children, is accompanied by marked cachexia, and is of unknown origin, though possibly infectious.¹ Synonyms of this affection are: Cardarelli's cachectic aphtha and Riga's disease. There was a pearly gray, flat ulcer on the under surface of the tongue which extended upward over the apex of the organ, and would not heal in spite of cauterization, etc. The child was desperately cachectic, and on the point of death when the injection was given. Within two days it picked up remarkably and recovered completely two weeks later. Locally, a solution

of potassium permanganate was used in the form of applications with a brush.

5. Simple Treatment for Ingrown Toenail.—Gasparini uses with success a very simple treatment for ingrown toenails in cases in which operation is for some reason impossible. He applies a soap poultice to the affected toe for twenty-four hours, and then lifts the edge of the nail from its bed as much as possible. He powders some burnt alum into the space between the nail and the ulcerated or granulating nail bed, and then inserts a piece of absorbent cotton between these surfaces, pushing the cotton as far inward and backward as possible. The patients are quickly relieved of their pain, and the treatment is repeated for several days. He was able to obtain cures within a week. Afterwards the nail is scraped to make it thinner and to reduce its pressure on the nail bed, and the patients are cautioned to observe the strictest cleanliness, and to wear a strip of cotton in the ungual fold.

ROUSSKY VRATCH.

January 8, 1905

1. Sodium Perborate, By P. G. MELIKOFF and L. V. PISARZHEVSKI.
2. The Antiseptic Properties of Sodium Perborate, with Some Observations on Its Therapeutical Uses, By D. P. KISCHEVSKY.
3. Volume Meter for Anthropometric Measurements in Pathologicoanatomical Investigations, By TH. Z. OMELTCHENKO.
4. Acinesia Alginoessa, By M. O. SCHAEKEVITSCH.
5. Röntgen Rays in Trachoma, By A. G. VASSIUTINSKY.

1. Sodium Perborate.—Melikoff and Pisarzhevski prepare sodium borate by adding caustic soda solutions to commercial hydrogen peroxide solutions until a flocculent precipitate takes place. The latter is then filtered off and the filtrate is used for the preparation of perborate compounds. For this purpose, the authors take 100 grammes of borax and dissolve it in 900 c.c. of water, to which 28.5 c.c. of sodium hydrate have been previously added. The mixture is allowed to cool for several hours, when crystals of sodium perborate will be found deposited at the bottom of the vessel. A better product is obtained by employing the chemically pure hydrogen peroxide. The crystals are obtained by siphoning the supernatant fluid and drying in the air or the oven. If kept dry in the form of a powder, sodium perborate can be kept indefinitely. It contains 10.3 per cent. of active oxygen, and corresponds to 22 per cent. of hydrogen peroxide. Perborate is soluble in water, and the watery solution has an alkaline reaction.

2. Therapeutics of Sodium Perborate.—Kischencki investigated the bactericidal and other properties of sodium perborate, the new compound of hydrogen peroxide described in the preceding article. He found that, in general, sodium perborate corresponds to hydrogen peroxide, but it has several features which are distinctly superior. The perborate can be used externally in the dry form for example in the treatment of

¹ It was also described by the Italian clinician Fede, who styled it "sublingual fibroma."—Ed.

ulcers. The watery solutions of sodium perborate have an alkaline reaction, which renders them suitable in the treatment of catarrhal conditions of the mucous membranes. For bactericidal purposes the saturated solutions of sodium perborate may be used, which contain an excess of the compound in suspension. It is only lately that manufacturers have been able to make a strong solution of hydrogen peroxide that would keep and could be sold in proper receptacles. On the other hand, sodium perborate can be kept very easily in the solid form, and solutions of any strength can be prepared whenever needed.

3. Volume Meter for Anthropometry, Etc.—Omeltchenko describes a new apparatus for the measurement of volumes of organs, etc. The apparatus consists of a metallic box arranged so that the amount of water displaced by an organ can be accurately measured. For this purpose the box is provided with a series of stop cocks at different levels.

4. Acinesia Algiноessa.—Schaikevich thinks that acinesia algiноessa (inability to move due to pain) is a symptom complex which is most often observed in the course of the psychoneuroses, and represents either an aggravation or a complication of the symptoms of the original disorder. The pains which are complained of in this condition are illusory, and the limitation in the power of voluntary motion is hypochondriacal in origin. The entire clinical picture of acinesia algiноessa is related to that of hypochondria, and the condition is probably a variety of hypochondria.

5. Röntgen Rays in Trachoma.—Vassutin-sky obtained favorable effects upon trachoma by means of the Röntgen rays. These rays diminished the infiltration, caused the disappearance of the granulations and of the pannus, and produced a pronounced improvement in the subjective signs of the malady. As a rule, however, trachomatous granulations disappeared but slowly under the influence of Röntgen therapy. The rays proved to be harmless in treating the eyes, and no evil effects were noted in any case, nor was pain experienced by the patients. The author thinks that the rays are of service in cases in which ordinary methods of treatment fail.

BOSTON MEDICAL AND SURGICAL JOURNAL.

February 23, 1905.

1. Eye Strain as a Factor in Functional Nervous Disabilities, By MYLES STANDISH.
2. Eye Strain as a Factor to Be Considered in Children Backward in Their Studies, By ALLEN GREENWOOD.
3. Eye Strain Considered as a Factor in the Production of Lateral Curvature of the Spine, By HENRY W. KILBURN.
4. Eye Strain and Reflex Phenomena of Nasal Origin, By HENRY H. HASKELL.
5. In What Cases Should Eye Strain Be Suspected? By EDWIN E. JACK.
6. Difficulties Encountered in the Prescription of Glasses, By FRED M. SPALDING.

1. Eye Strain and Nervous Disabilities.—Standish favors the views championed by Gould regarding the possible baneful effects of eye strain. He does not pretend to know whether the eminent gentlemen who figure in *Biographic Clinics* suffered from eye strain or not. Their symptoms could very well have been due to eye strain, but there is no evidence to show that they might not have had some other origin.

2. Eye Strain and Backward Children.—Greenwood believes that many backward children owe their incapacity to eye strain. Even really feeble minded children are often benefited by properly fitting glasses. Therefore all children backward in their studies and all feeble minded children should have their eyes carefully examined.

3. Eye Strain and Spinal Curvature.—Kilburn asserts his belief that an uncorrected refractive error is capable of inducing scoliosis, and that scoliosis is capable of producing myopia. Therefore in every case of marked tilting of the head to one side, or of increasing myopia or diminishing hypermetropia, the spine should be examined, and, in every case of spinal curvature, the refractive error should be carefully corrected. Eye strain and scoliosis act and react upon each other, in a vicious cycle, as do eye strain and neurasthenia. It is only by correcting both the scoliosis and the refractive error that the patient can be materially helped.

4. Eye Strain and the Nose.—Haskell calls attention to the nose as, at times, the producer or inducer of eye strain. He has seen "a hopeless nervous wreck" cured by an intranasal operation. He has notes of sixty-five cases in which refractive errors were decreased through operations upon the nose. In such cases glasses should not be prescribed until the nose has been attended to.

MEDICAL RECORD.

February 25, 1905.

1. Loss of Sight from Disuse of the Eye (Amblyopia Ex Anopsia), By B. ST. JOHN ROOSA.
2. A Review of the Recent Literature on the Relation of Human and Bovine Tuberculosis, By DAVID BOVAIRD, JR.
3. The Advantages of Performing Capital Operations in Selected Cases Without Anæsthesia, By J. J. BUCHANAN.
4. Four Cases of Chancre of the Lip, By CHARLES MALLORY WILLIAMS.
5. An Unusual Case of Pelvic Abscess, By W. H. COE.
6. Ear Complications of Scarlet Fever, and Their Treatment, By HERMAN JARECKY.
7. The Epileptic Criminal; with Report of Two Cases, By T. H. EVANS.
8. Higher Education a Cause of Physical Decay in Women, By F. W. VAN DYKE.

1. **Loss of Sight from Disuse.**—Roosa by the term *amblyopia ex anopsia*, means that condition where use of the eye has been given up, because to use it involves double vision, the maculæ luteæ being no longer in exactly corresponding positions, as is the case in any form of strabismus. He reports the following case: Recovery of sight in amblyopia ex anopsia. Convergent strabismus with amblyopia from early childhood. Operation; over effect. Second operation; cure of strabismus. Loss of fellow eye from accident. Recovery of sight in amblyopic eye. This case goes to show that the amblyopia in the deviating eye is functional and that the power of sight may be recovered. Incidentally the case furnishes evidence that the retinal perceptive layer does not cease to develop, if not used, and can be called into activity.

2. **Tuberculosis.**—Bovaird concludes: (1) Human tuberculosis can be transmitted to cattle, but with difficulty, and it seems highly improbable that such transmission plays any great part in the production of the disease among cattle. (2) Bovine tuberculosis can be transmitted to man, but the evidence that such transmission occurs under ordinary circumstances is extremely scanty and it is highly improbable that such transmission plays any important part in the spread of the disease in man.

3. **Operations Without Anæsthesia.**—Buchanan has performed a large number of operations without the aid of anæsthesia. He asserts that the pain produced by operation has been greatly exaggerated. Most patients, even those of tender years, will bear capital operations without any anæsthetic and without much complaint. The following is a partial list of operations the author has performed without anæsthesia: Appendectomy; amputation of limbs; resection of shoulder joint; laparotomy for relief of intestinal obstruction by bands; herniotomy; gastrostomy; prostatectomy; craniotomy.

6. **The Ear in Scarlet Fever.**—Jarecky wishes to emphasize the following points: (1) The necessity of paying attention to the removal of hypertrophied tonsils, adenoid vegetations, and nasal

obstructions in all young patients, so that when subjected to the strain of scarlet fever they may avoid the principal method of ear infection. (2) Owing to the rapidity with which destruction of aural tissue and extension of infection take place in this disease, as soon as the tympanum shows signs of exudation and the membrane of bulging, a paracentesis should be immediately performed. (3) Repeated examinations of the ear, especially in infants and children, should be made on account of the uncertainty of the symptoms.

7. **The Epileptic Criminal.**—Evans asserts that the two cases he reports, taken in connection with similar cases, warrant the following conclusions: "(1) The essence of crime is in the intention, and the ability not so to intend. (2) No punishment is adequate to any crime; not only restraint after a crime has been committed, but effort to hinder any such deed, is preferable always. (3) The victims of epileptics ought to have legal ground for suit against the community as well as against those in charge of the epileptic. (4) Reservations ought to be established, in which degenerates and the morally irresponsible could be colonized and treated, allowing all possible freedom of initiative for useful and safe pursuits therein. (5) Marriage of neurotics should be regulated. We can afford to lose the few sane descendants if we could also cut out their degenerate progeny. Democratic principles encourage, in this as in other matters, the average, and discourage the exceptional or abnormal—great or small. (6) All epileptics are to be viewed with suspicion. Many cases of psychic erraticism, cranks, and mistaken reformers, are to be taken as examples of epileptic psychic equivalents. The major forms of epilepsy may not prove so dangerous to the community as these veiled manifestations."

MEDICAL NEWS.

February 25, 1905.

1. The Expectant Treatment of Appendicitis. An Excursion Into the Field Between Surgery and Medicine, By A. C. BERNAYS.
2. Observations Upon the Morphology and Classification of the Mycobacterium (Bacillus) Tuberculosis, By CHARLES F. CRAIG.
3. Clinical Studies in Ureteric Meatoscopy, By WALTER C. KLOTZ.
4. Sprains of the Knee and Ankle Joints, By J. T. WILSON.
5. Syphilis of the Lung Simulating Phthisis, By WILLIAM E. HUGHES and ROBERT N. WILLSON.

1. **Appendicular Disease.**—Bernays devotes most of his space to combating the teaching of Ochsner regarding the use of purgation and enemata in the treatment of certain stages of appendicitis. The author holds: (1) That, if seen early, cases of acute appendicitis should be treated by immediate operation. (2) If operation is refused or if the best time for operating has passed then the best results will be obtained by employing regularly cathartics and copious warm enemata. The diet should be liquid, and as restricted as possible; the patient should be confined to bed and large, moist, warm, antiseptic poultices should be ap-

plied over his belly. (3) The so called interval operation is practically without mortality.

2. Tuberculosis.—Craig asserts that the so called tuberculosis bacillus is not a bacillus at all, but is in all probability an actinomyces. He has been very greatly impressed by the effect which a tropical climate seems to have upon the growth of this organism. In the sputum of tuberculous troops returning from the Philippines he has observed clubbed, budding, and branching forms of tubercle bacilli (?). The author does not believe that these morphological changes are due to degeneracy. They probably indicate very free and luxuriant development.

3. Ureteric Meatoscopy.—Klotz reports a study of twenty cases in which he noted the appearance, through a cystoscope, of the ureteral openings. No formal conclusions can be drawn. It seems probable that further studies will make it possible to often reach a correct diagnosis by a simple inspection of the ureteral orifices. A number of illustrations are given of abnormal appearances of the ureteral openings which are at times of diagnostic value.

4. Sprains of the Knee and Ankle.—Wilson's advice may be summed up as follows: (1) For sprains of not too great severity hot water applications and rest. (2) For more severe sprains, hot water applications followed by gentle massage for ten minutes and then partial fixation by means of adhesive plaster. (3) For sprains of the greatest severity, rest with local applications of evaporating lotions for the first few days, then fixation by means of a plaster dressing. In the case of the knee joint aspiration will hasten the cure.

5. Lung Syphilis.—Hughes and Willson report a case which they believe to have been lung syphilis. The patient recovered after taking potassium iodide. The diagnosis was by exclusion and the so called therapeutic test. The clinical history resembled that of bronchopneumonia.

AMERICAN MEDICINE.

February 25, 1905.

1. Relation of Pathology to Other Sciences, By J. ORTH.
2. Nephroureterectomy for Tuberculous Disease, with a Description of a New Technic,
By EDWARD REYNOLDS.
3. The Society of Sanitary and Moral Prophylaxis: Its Object and Aims, By PRINCE A. MORROW.
4. The Abuse of Purgation Before and After Operation,
By I. S. STONE.
5. On Cystoscopy, By HENRY DAWSON FURNISS.
6. Suspected Embolism of the Superior Mesenteric Artery,
By JAMES A. NYDEGGER.

2. Nephroureterectomy.—Reynolds reports seven cases of nephroureterectomy. The new expedient for facilitating the operation consists in obtaining negative pressure in the wound and so having a clear and open operative field. This is accomplished in the following manner: Thin patients are placed on the table on the side opposite to the affected kidney. They are held in this position by means of hard pillows and straps. The

incision recommended goes from the last costal cartilage to near the anterior superior spine of the pelvis. As soon as this incision is made the falling forward of the intestine and abdominal wall causes a negative pressure. The deep parts of the wound are thus held open. With very fat patients it is at times necessary to tilt the body slightly backward or to elevate the pelvis. A little experience will make it easy to select the best position for each individual case. The author reports very minutely all the details of his techniques.

4. The Abuse of Purgation.—Stone sums up his views on purgation as a routine treatment before and after operation thus: "Excessive purgation should be restricted because it is enervating to the general system. It produces great irritation to the mucous lining of the bowel. It may add to some of the dangers we are most anxious to avoid: ileus and paresis. Purgatives have very little effect in limiting the amount of extraperitoneal exudate and fluids. Instead of calomel and saline purgation, bland evacuants such as castor oil should be used before abdominal section. The use of suitable bland non-fermentative foods is desirable until just before operation in weak patients. After operation limit peristalsis; give only small quantities of food and drink by mouth. Rarely give opium. Enemata should be administered to relieve distention and cause peristalsis in downward direction. After normal peristalsis laxatives should be given as required."

5. Cystoscopy.—Furniss writes a very general article on the advantages of cystoscopy. The various forms of instruments in general use are referred to.

6. Suspected Embolism.—Nydegger reports a case of what during the patient's life was thought to be intestinal obstruction, and which at autopsy was suspected of being a case of embolism of the superior mesenteric artery. The embolus, however, was not found.

LANCET.

6. The Rational Treatment of Fractures, By J. S. MELLISH.
7. Pyloroplasty: Remarks on Seventeen Cases of Pyloroplasty with After-History for Periods Varying from Ten Years to Five Years and Three Months After Operation, By R. MORISON.
8. General Gonococcal Infection, By W. H. WYNN.
9. A Hat Pin Four and Three Quarters Inches Long in the Cæcophagus Producing a False Aneurysm of the Superior Mesenteric Artery,
By H. D. ROLLESTON and T. R. C. WHIPHAM.

10. Mandibular Processes Associated with Double Harelip and Cleft Palate, By W. L. WOOLCOMBE.

2, 3. **Duodenal Ulcer.**—Moynihan's article is based on a series of 52 cases of duodenal ulcer with 4 deaths. In 7 patients the ulcer was perforating; of these, 2 died. In 22 cases there was association with gastric ulcer, and 1 death. In 23 cases duodenal ulcer alone was present, and 1 case proved fatal. Duodenal ulcer is far more frequent than has been formerly believed, and it is often associated with gastric ulcer. The symptoms are often perfectly characteristic and admit of an unhesitating diagnosis. The ulcers are usually situated in the first part of the duodenum, and are generally solitary. They may occur at any age, having been observed at the age of three days and at ninety-six years. They differ from gastric ulcer in being more common in men than in women. The symptoms are pain, hæmatemesis, and melæna. In a number of cases the ulcer remains latent for long periods. The pain is usually of a burning character, and when severe is always worse to the right of the middle line. If the pain does not come on for from two to four hours after a meal, the ulcer is either at the pylorus or very near it. Among the possible causes of pain are the irritation of the ulcer by the acid gastric juice, pyloric spasm, distention of the stomach or duodenum by gas, and the occurrence of localized peritonitis. Hæmatemesis and melæna probably occur more often than is supposed. The complications are hæmorrhage; perforation, acute, subacute, and chronic; cicatricial contraction and induration, causing stenosis of the duodenum; cicatricial contraction narrowing the ampulla of Vater and obstructing the outflow of bile and pancreatic juice; periduodenitis; cancer; compression of the portal vein; diseases of the gall bladder or bile ducts; and diseases of the pancreas. Clarke reports the case of a sailor, aged fifty-five years, suffering from a gastric ulcer of six years' standing. Six years before he had been shipwrecked, and for sixteen days had only maggoty bread to eat and putrid water to drink. A few days after being rescued he was taken with violent pains in the stomach and attacks of severe vomiting. Retrocolic gastrojejunostomy was performed. The author holds that this case strikingly confirms the suggestion of Robson and Moynihan that oral sepsis is responsible for many gastric and duodenal ulcers.

4, 5. **Gout.**—Watson has sought to determine by animal experiments whether an excessive meat diet exerted any specific action on any of the ductless glands. Rats and chickens were used: in poultry a meat diet induced hypertrophy of the thyroid gland. In rats there was a striking change in the character of the secretion, with catarrh of the epithelial lining of the vesicles. The author concludes that in human beings, as a result of the excessive use of meat, the character of the thyroid secretion is altered. This defect may be remedied by the administration of thyroid gland. He has given small doses of the extract in two inveterate cases of chronic gout, and in both the symptoms were relieved to a striking

degree. Shearer states that the one factor common to all antecedents of gout is the tendency to the production of an excess of carbonic acid in the blood. Muscular exertion increases it; alcohol and carbohydrates produce water and carbonic acid as the end products of their metabolism; nitrogenous diet increases the metabolism of carbohydrates. The sum of the small additions to the blood pressure consequent upon the excess of carbonic acid, is sufficient to account for the arterial hypertrophy. The effect of the chronic irritation of blood overcharged with carbonic acid would be increased connective tissue. The author includes arteriosclerosis and chronic interstitial nephritis with gout as conditions in which the main antecedent factor is the excess of carbonic acid in the arterial blood.

6. **Fractures.**—Mellish states that there is much room for improvement in the treatment of fractures, and urges the more extended employment of massage and as much freedom and movement as can be permitted in each individual case. Once the fractured ends of the bone have been approximated, the surgeon's chief duty is to keep the circulation of the limb in a healthy state. For this purpose the less splinting that can be done the better.

7. **Pyloroplasty.**—Morison has followed up twenty cases of pyloroplasty performed for stricture of the pylorus. One case could not be found and two were dead, one from cancer of the pylorus, and one from pulmonary tuberculosis. In the remaining seventeen cases the symptoms have recurred in three, necessitating a further operation. Of the remaining fourteen cases, in eight the result was perfect. In six, symptoms more or less painful were complained of. The author thinks pyloroplasty the best operation for stricture of the pylorus, and expresses surprise that it is falling into disuse and being replaced by gastroenterostomy. The cases suitable for pyloroplasty are those with a history of long standing stomach trouble, foul abundant vomiting towards night, thin patients with dilated stomachs and with a palpable movable nodules in the pylorus. He restricts the use of gastroenterostomy to cases of serious gastric ulceration which have resisted a trial of ordinary measures.

8. **General Gonococcal Infection.**—The author bases his remarks on three cases of gonococcal pyæmia recently observed by him. Gonorrhœa shows a great family resemblance to pneumonia, rheumatism, and cerebrospinal meningitis, in all of which a diplococcus has been proved to be the ætiological factor. In each case there is a seat of election, and the disease often becomes generalized and produces a septicæmia, the serous surfaces being especially affected. All have in common a marked leucocytosis, and one attack of one of them appears to predispose to others. In one of the author's cases, the gonococcus was obtained during life in pure culture from the blood. In the other two the diagnosis was made post mortem. In all three the primary seat of infection was the urethra. In two cases subcutaneous abscesses were present—an extremely rare

complication of gonorrhœa. The lesions and symptoms of the general infection depend mainly upon: 1. Direct infection with the gonococcus itself. 2. An absorption of a toxine—gonotoxine. 3. Mixed infection with other germs. There are no special clinical features to differentiate gonorrhœal infection from other pyæmias: a positive diagnosis can be made only by bacteriological examination of the blood or of any accessible lesions.

BRITISH MEDICAL JOURNAL.

February 11, 1905.

1. Removal of the Contents of the Anterior Triangle of the Neck in Cases of Malignant Disease of the Tongue, By H. T. BUTLIN.
2. On the Thalamus, By G. MANN.
3. On the Pathology and Treatment of Leprosy, By E. R. ROST.
4. A Second Case of Cutaneous Anthrax Successfully Treated by Scavo's Method Without Excision, By A. BOWLEY and F. W. ANDREWS.
5. The Medical Worthies of Cumberland, By H. BARNES.
6. Ergophobia, By W. D. SPANTON.

1. **Removal of Glands in Cancer of the Tongue.**—Butlin, in operating in cases of cancer of the tongue, removes the glands of the anterior triangle of the neck, on the same principle as clearing out the contents of the axilla in cancer of the breast. The glands which are apt to be diseased are the submental, the submaxillary, the inferior carotid, and the parotid or superior carotid groups. In removing the last it is almost always necessary to cut away a portion of the parotid salivary gland itself. Unfortunately we cannot rely upon only one group of glands being affected by cancer of a particular part of the tongue. The author operates upon the tongue first, and as soon as the patient is fit for the second operation, it is performed. By this is meant the patient's being able to take his food quite comfortably by mouth and the wound so far healed as to make infection of the wound in the neck improbable. This usually takes about nine days. Of 28 cases in which the glandular contents of the anterior triangle of the neck were removed, 10 were successful, and only 4 died of affection of the glands without recurrence in the mouth. Of 31 cases where the glands were not removed; only 5 were successful, and 8 died of affection of the glands without recurrence in the mouth. In every case of cancer of the tongue, even in the very earliest period, the author strongly recommends, not only removal of the disease of the tongue, but also if the disease is unilateral to have the anterior triangle completely dissected out, and if the disease of the tongue is in the middle line to have the contents of both triangles taken out.

3. **Leprosy.**—Rost claims that when the chlorine salts are removed from nutrient media, the various acid-fast bacteria (*Bacillus tuberculosis*, *b. lepra*, and *b. Lustgarten*) grow thereon with the greatest ease and rapidity. The medium is prepared by passing superheated steam over beef extract soaked in pumice stone in bottles in an autoclave. In this medium the tubercle bacillus grows in one to three days and that of leprosy in three

to five days. The characteristic appearance is a curly white stringy heavy deposit at the bottom of the tubes, very hard to shake up. By dialysis of nutrient agar a solid medium can be obtained on which the bacillus of leprosy grows at first as a white, and later as a brick red, curly, thick growth. The bacillus of leprosy when stained, may be distinguished from other acid-fast bacteria, by the following characteristics: 1. It retains the stain of acid dyes much more than the other bacteria of this class. 2. It is more irregular than the tubercle bacillus, and not curved, and is somewhat smaller. 3. It contains small oval spores within itself, which are highly refractile. 4. It has a beady appearance due to the presence of these oval spores. 5. Like the tubercle bacillus it may grow out into cultures into long branching filaments, but oval spores may alone be visible at times. 6. In the body it is found in great numbers inside epithelial cells, generally in the middle of the cells, whereas the tubercle bacillus is found in small numbers inside giant cells at the polar ends. To obtain the bacillus the fresh granulations of the ulcers of a case of leprosy are scraped and examined. If found the described medium is inoculated with a piece of tissue. The toxine of the cultivation of the leprosy bacillus is called, by the writer, "leprolin." It is prepared on similar lines to the preparation of tuberculin. It produces a powerful reaction in a case of leprosy, which may last three days or more. The temperature runs up to 104° F., and the anæsthetic areas become red, hot, and swollen. Ten c.c. of leprolin are given at a dose, and the injection causes considerable smarting, owing to the glycerine in which the leprolin is preserved. The most remarkable effect of the injections is the sudden return of sensation in the anæsthetic patches. The shooting pains are also relieved, the ulcers heal up, the subcutaneous nodules disappear, and the skin assumes a normal appearance. As a rule, the severity of the reaction may be taken as an index of the benefit that is likely to occur. The injections are usually given about once in two weeks: the writer has given over 400 injections and in every case the disease has ceased to advance, and there have never been any bad symptoms. One hundred cases are now under treatment in Burmah: four have been cured, and the great majority have been greatly benefited. It is not known how the bacillus enters the body: but the theory that it is through the consumption of badly cured fish is certainly erroneous.

4. **Anthrax.**—Bowley and Andrews report the case of a man aged thirty years, a horse hair dresser, suffering from a characteristic anthrax lesion, and from which typical anthrax bacilli were obtained. Forty c.c. of Scavo's anthrax serum were given, and its beneficial action could be noted at once. The patient was discharged cured in two weeks' time. Only nineteen hours after the injection not a single anthrax colony could be obtained from the vesicles, although previously the bacilli were abundant. Special attention is called to the increase in the œdema which follows the injection of the serum, and which may excite alarm for a little while.

Letters to the Editor.

A CONUNDRUM SOLVED.

126 EAST TWENTY-NINTH STREET,
NEW YORK, February 16, 1905.

To the Editor,

Sir: Some colleague gave me what he thought was a conundrum: Why do we say *tænia lata*, but, *tænia* being feminine, *tænia solium*?

My answer was this: *Solium* is the Latinized genitive plural of the Greek word *σόλος*, or disk. The Latins changed the ending of the Greek genitive plural, when it was *ων* into *um*, and when it was *ων* into *ium*; here, therefore *σόλων* into *solium*.

It interested me to consult the different medical lexicons, and they cause me some amusement in their attempted explanations of *tænia solium*. French lexicographers translated it *ver solitaire*, and some Latin scholar has given the name *tænia solitaria*. He was horrified of the supposed incorrectness of "*solium*," but the most profound nonsense I found in a German lexicon. Here it reads: *Solium* is a throne or an easy chair or a sarcophagus, in later Latin it means sole, while sole was *solum* in classical Latin. He also brings the Arabic *sosl* and the Syriac *schuschl* into play; it would then be an armed tapeworm, but he confesses that this explanation is rather forced.

Looking at the picture of *tænia solium* in Foster's Dictionary, I become at once convinced that *tænia solium*, a tapeworm composed of disks, was certainly an ideally correct name. A. ROSE.

"THE ABUSE OF WATER DRINKING IN DIS-
EASE."

MEXICO CITY, February 8, 1905.

To the Editor,

Sir: In regard to Dr. Manges's remarks about the waters of Carlsbad and the methods there used, I am forced to believe that he is unacquainted with the physicians of Carlsbad and their methods in the use of the water. It seems that he has in mind the article of Dr. Hlavacek, written in the early forties, wherein it is stated that the usual custom was to drink between 50 and 60 glasses of the waters daily. In those days Balneotherapeutics was based solely on empiricism and not on the principles laid down by physiology, pathology, and internal medicine, as it is to-day. This wholesale water drinking has entirely ceased. Above all, all physicians practising at Carlsbad are registered graduates of Austria and have passed a rigid course in physiology and pathology, and are therefore thoroughly acquainted with the evils of a large amount of water drinking on diseased metabolism and especially the heart.

So far as I know, and following my own custom, every patient coming to Carlsbad to take the "*Kur*" and placing himself under "*the so called guidance of the physician*" is given a thorough and complete examination, and especially regarding the cardiac function. It is unnecessary to go into

the uses and methods of the Carlsbad "*Kur*;" but sufficient American physicians have taken the cure—some under my personal supervision—and have never complained of the symptoms due to the abuse of water drinking. There are some cases where people who come to Carlsbad do not place themselves under our "*so called guidance*" and who think they are better and more rapidly cured by drinking enormous quantities—paraphrasing "*drink all you wish for five cents*."

I must admit, that we do send patients to Nauheim, either because they have been badly advised to come to Carlsbad, having a cardiac lesion, or at their own desire wish to avail themselves of the carbonic baths and the enjoyable surroundings of Nauheim as an after-cure. It is the first time that I have read that a patient must be sent to Nauheim owing to the evil effects of a Carlsbad "*Kur*." It certainly seems strange, that the best European authorities, such as Leyden, Nothnagel, von Noorden, Klemperer, Naunyn, Boas, and others, should send a very large number of their patients to Carlsbad, if these abuses were such as the article imports.

M. GERSTL, of Carlsbad.

Proceedings of Societies.

ASSOCIATION OF CLINICAL ASSIST-
ANTS OF WILLS'S HOSPITAL,
PHILADELPHIA.

Meeting of January 18, 1905.

Dr. J. HILAND DEWEY in the chair.

Gumma of the Iris.—Dr. STANLEY S. SMITH read a report of a case of gumma of the iris and ciliary body occurring in the clinic of Dr. CHARLES A. OLIVER. The case presented all of the characteristic symptoms of the condition, and was fast becoming well. Dr. Smith stated that it was very instructive to note the secondary rapid diminution of vision produced by haze in the media which had been probably caused by a deposition of the gummy infiltrates into the chambers of the eye.

In the discussion, Dr. JOHN T. KRALL commented upon the comparative painlessness of specific cyclitis and the character of the infiltration into the aqueous and vitreous humors which was chiefly composed of round cell exudates. In support of the belief of others that gummata of the ciliary body usually occur on the upper border of the cornea, he had seen but one in which the swelling was situated on the lower side.

The various methods of administering mercury were informally discussed, the consensus of opinion being in favor of the use of mercurial ointment by inunctions.

Interstitial Keratitis.—Dr. JOSEPHINE W. HILDRUP read a paper upon ten cases of interstitial keratitis, nine of which had been studied in the clinic of Dr. OLIVER, and the remaining one in her own clinic at the Woman's Hospital. The ages of the cases varied from six years to fifty-eight years. The dyscrasia had been very carefully studied in all. Females had been prepon-

derant in the series. With but one or two exceptions, all of the cases had passed on to resolution.

The discussion, which was quite informal, embraced the forms of treatment which were the most favored by the surgeons in the institution. Dr. JAMES A. KEARNEY stated that he had seen much good from the use of inunctions of protiodide of mercury. Dr. DEWEY spoke favorably of the use of dionin, stating that it had hastened resolution in a number of cases which he had seen. He had not had much experience with subconjunctival injections and had seen some unfortunate results, such as conjunctival ulceration, giving rise to disfigurement from their use. Dr. KEARNEY exhibited a case in which the right eye was being treated by the ordinary routine methods, supplementing these by subconjunctival injections of common salt solution in the left eye; the latter organ (although the first involved) seeming to grow well much more rapidly than its fellow.

Dr. KRALL stated that he had learned to share the opinion of others that if injections were made under the conjunctiva, their effects would be to produce a number of adhesions between the bulbar conjunctiva and Temon's capsule; and stated that even though the injections were made into the capsule, their good results were but transitory as adhesions were sure to occur. In other words, he, with many other authorities, believed that such injections did more harm than good.

Double Pterygium.—Dr. KEARNEY presented a case of double pterygium from Dr. WILLIAM ZENTMAYER's clinic, in which one eye had been operated on by the von Arlt method and the other by the McReynold's. He exhibited a case of entropion of the upper lid, taken from the same clinic, in which a Hotz operation had been performed with little or no improvement, followed by a Jaesche-Arlt operation, which afforded a very satisfactory result. He also showed a case of entropion from the clinic of Dr. FRANK FISHER in which the cilia had been transplanted and the tarsus removed, giving most excellent results.

In the discussion, Dr. KRALL was of the opinion that the McReynold's operation had no advantage over the von Arlt. He believed that every case should be treated on its own merits, one method of operation not being applicable to all. Dr. DEWEY, Dr. MILTON A. ROBISON, and Dr. SMITH cited several cases in which different plans of treatment had been most successfully applied.

To Study Cerebrospinal Meningitis.—Dr. Edward Waitzfelder has been experimenting at Gouverneur Hospital, New York, in the treatment of cerebrospinal meningitis with diphtheritic antitoxine. The idea was first suggested by Dr. Wolf, of Hartford, Conn. In speaking of the method of treatment, Dr. John W. Brannan, president of the board of trustees of Bellevue and allied hospitals, said: "I want more time to study the question, but the results of the antitoxine treatment seem to be of great value."

Book Notices.

Practical Dietetics. With Reference to Diet in Disease. By ALIDA FRANCES PATTEE, Graduate, Boston Normal School of Household Arts; Instructor in Dietetics, Bellevue Training School for Nurses, Bellevue Hospital, New York City. Second Edition, Revised and Enlarged. Pp. xvi+312. New York: Published by the Author.

The second edition of this handy little volume is considerably enlarged and seems to have been carefully revised. The work appears to be excellent and well arranged, and especially suited to the needs of the sick room and the hospital. The inclusion of dietaries suited to various conditions justify the claim of the book to be considered as a treatise on practical dietetics, and the frequent references to various standard medical works is an excellent feature. As a whole the volume will be of undoubted service to the general practitioner, as well as to the nurse.

Transactions of the Royal Academy of Medicine in Ireland. Vol. XXII. Edited by JOHN B. STORY, M. B., F. R. C. S., General Secretary; Surgeon to Royal Victoria Eye and Ear Hospital, Dublin. Dublin: John Falconer; London: Baillière, Tindall, & Cox; Edinburgh: James Thin; Bristol: John Wright & Co., 1904. Pp. xxxix+439.

This volume contains a number of interesting papers, some of which are well illustrated, that were read before the different sections of the academy in 1903. It sustains the excellent reputation of the preceding volumes.

Miscellany.

X Ray Therapeutics.—Ewart, in the *Edinburgh Medical Journal*, for November, 1904, speaks of the similarity of the emanations from radium and the x rays. The physical laws governing the x rays should be understood in order to use them efficiently, he therefore finds it desirable to refer to some of them. The vacuum tube changes in resistance, becoming more rarefied in proportion to the discharge which passes through it.

The rays arise at the anticathode, and that point should be taken in estimating their relative intensity at any distance.

The exposure should be inversely as the square of the distance. The intensity of the ray in the reverse aspect of the tube will depend (1) upon the thickness of the photographic plate, and (2) upon the penetrating power of the ray.

An apparatus which is used for therapeutical purposes must maintain absolute constancy, or as near that as possible. Accumulators kept well charged are more constant than the current taken from the main by means of a transformer.

To ensure greater constancy the tube must not be allowed to get hot; this also will be a means of prolonging its life.

The screen and the operator's hand must not be used to judge of the penetrating power of the

rays on account of the lack of an absolute standard and the danger of such practice.

The proper interval between the terminals is found by experiment and must be maintained, only the duration and the interval of exposure must be varied. Avascularity and the opacity of the tissue are concerned in the production of a reaction.

The differences in the duration of the latent period of the reaction are due to variations in the intensity of the ray, and lack of uniformity in the accessory details of application.

The reaction presents the ordinary features of an inflammation, the various stages of which are greatly prolonged.

Examination of tissues which have been subjected to x rays shows in one instance that the epithelial cells undergo cystic degeneration and disappear, and in another that the cells are invaded by leucocytes, the vessels dilated, and that inflammation exists.

The author thinks the x rays a clumsy means for the treatment of lupus, and not as efficient as the Finsen light. There are not a few recurrences. The benefit to malignant disease by means of x rays is questionable. Rodent ulcer being superficial is usually benefited. Sarcomata are seldom improved by them. Pain is frequently relieved in hopeless cases, but the relief cannot be compared to that which is obtained from a hypodermic of morphine. If the patient is too feeble, or the growth too extensive for removal, or has recurred repeatedly the rays may be used.

In eczema relief is rapidly obtained, but is only temporary; in tinea sycois relief is obtained with equal rapidity and is permanent. In leucocythæmia much benefit has been obtained by gentle x ray treatment.

On the Question of Autointoxication in Ileus.

—Clairmont and Ranzi, in *Fortschritte der Medizin*, for October 20, 1904, report the results of extensive experiments with reference to the poisonous effects of the contents of the intestine in experimental work as well as in ileus in human beings. Their conclusions were that in both series of experiments toxic substances were formed in the intestinal contents. The experimental ileus was produced by means of a wick, which was believed to be better than silk or a drainage tube. The contents of the intestine which were accumulated by this means were then carefully filtered. The filtrates showed the following peculiarities:

1. Animals which were used for experiment showed the same typical phenomena after injection of the filtered material, and in most of the cases death resulted quickly. The symptoms were independent of the manner in which the ligature was applied and the species of animal, but were dependent upon the relation of the substance to the weight of the animal. The noteworthy symptoms were rapid breathing, dilated pupils, increased reflex irritability, clonic and tonic spasms.

2. These symptoms were also present after injection of aerobic bouillon culture filtrates. The development of poisons was observed, not only in

the body of the animal experimented upon, but also in the test tube.

3. The poisonous action of the filtrates was not materially influenced by heat.

4. The filtrates lost their effectiveness after they had been kept some time.

5. When normal brain tissue was added to the filtrate the poisonous effect seemed to be neutralized.

6. Some of the filtrates showed an intense hæmolytic activity under the influence of heat.

7. Cytolytic activity was also shown by the filtrates. The same peculiarities were evident when filtrates obtained from ileus in the human being were used. The symptoms which were observed after injection of the filtrates in animals were similar to those which were observed in human beings. They included such nervous phenomena as coma, delirium, and spasms.

The authors believe that the severe phenomena in ileus in human beings are mainly explained by the theory of intoxication rather than by the theory of reflex action. They have endeavored to reduce their investigations to a practical basis by attempts at producing immunity by means of opotherapy. The number of their experiments in this direction is still too small to permit them to draw comprehensive conclusions.

The Surgical Treatment of Infantile Paralysis.

—Wiener, in *Medicine*, for December, 1904, defines infantile paralysis as a sequel to a preceding inflammation of the anterior horns of the gray matter of the spinal cord, which terminates in more or less destruction of the ganglion cells. The muscles which are supplied by the diseased nerves, being deprived of their trophic centres, degenerate. The muscle loses its function and lipomatous tissue develops. The muscles may be destroyed or only weakened. If not destroyed they tend to regenerate, this tendency continuing to the seventh or ninth month. After this period no further improvement will take place and the case should then come to the notice of the surgeon. The surgical treatment is based on physiological principles. If there is lack of muscular tonus the muscle is like an overstretched rubber tube. It may not be paralyzed, though useless, and in such a case shortening of the tendon may restore function to the muscle. Relief is sometimes possible by means of a judiciously applied apparatus, but such a method is much slower and less effective than surgical treatment. If a muscle has undergone lipomatous degeneration its function can be restored only by supplying new contractile substance or by connecting its tendon with a healthy muscle. The tendon of the power giver may be severed and grafted to the tendon of a receiver, or there may be a division of the function of the power giver by splitting off a portion of its tendon. According to the direction which the split portion has to take there may be a descending, ascending, or mutual transference of function. The descending practically creates a muscle with two tendons, having different insertions. The mutual rests on the same principles, while the descending is a lateral connec-

tion between the paralyzed and the healthy tendon. The descending method does not interfere with the normal blood supply of the transplanted tendon.

Nervous energy should be borrowed from muscles of similar function, if possible. A tendon must always be transferred in a straight line. The tendomuscular flaps act best when there is tension in an overcorrected position.

As rivals to tendon grafting are, (1) the periosteal method of Lange by which the tendon is sewed to the periosteum with silk at the proper point; (2) grafting of muscle to muscle. The leg is the ideal extremity for tendon grafting. The incisions should be large, and the plan of the operation should be worked out in advance. The skin is united by a continuous silkworm suture, starched bandages hold the limb in an overcorrected position, and in a week a light plaster of paris or celluloid dressing may be substituted. The patient is able to be about on crutches three days after the operation has been performed, and ten days later he is allowed to use the extremity. The plaster of paris cast should be worn from four to six weeks. Surgical procedures have been sufficiently satisfactory to warrant their recommendation for infantile paralysis. Massage and electricity should be given for at least a year after the operation.

Diagnosis of Abscess of the Liver.—De Burn, in the *Revue de médecine*, for November 10, 1904, calls attention to the mistakes which are often made, especially in the East, by allowing intermittent or remittent fever to be regarded as proof positive of malarial congestion of the liver instead of abscess, although frequent careful examinations may have been made. The ordinary means of diagnosis is often insufficient to determine the presence of an abscess in the liver, and even puncture may deceive one in regard to the true situation.

No one will deny the value of such evidence as increase in the size of the liver, hepatic, and scapular pain, oedema of the abdominal wall, fever, and general malaise, but, in addition to these signs, the author lays stress upon the condition of the tongue, the symptoms produced by exploration of the chest, and certain peculiarities of the pulse and temperature. In subacute and chronic abscess of the liver the tongue is especially inclined to present an appearance which has not been sufficiently emphasized by writers upon these subjects. It gradually sheds the coating which covered it, the tip and edges become red, the whole organ becomes dry, and three lines appear, running the length of its face aspect, two lateral, and one median, uniting at the tip. If it is protruded from the mouth it is without its natural suppleness, is fiery red, and feels to the finger like a piece of wood. With the tongue in such a condition with fever which does not coincide with chronic diarrhea or with urinary troubles one should be suspicious of the presence of abscess of the liver. The condition of the tongue which has been described may be the only pronounced

symptom, but if it is connected with indistinct pain in the right shoulder, and in the liver, and with an attack of intermittent fever, the diagnosis of hepatic suppuration is almost certain to be the correct one.

Apyrexia may also attend the development of an abscess of the liver, but this will give place to fever in connection with indigestion, overwork, excitement, and various other causes. Apyrexia may occur also after a longer or shorter period of fever, coinciding with improvement in all other symptoms and deceiving the patient with the thought that he is getting well. The improvement may last a few weeks or months, and then upon the slightest provocation the bad symptoms will return with increased severity.

Abscess of the liver is almost always attended by important changes in the pleura. Pleurisy in this combination is always dry, except in cases in which the pus penetrates from the liver into the thorax, and friction sounds are usually heard at the posterior aspect of the base of the right lung. These sounds are sometimes heard over the entire posterior aspect of the right lung, and occasionally over the left lung. The pleurisy is not usually very painful, but it may throw the physician off his guard concerning the condition of the liver, and he may make a diagnosis of dry rheumatic or tuberculous pleurisy, of intercostal neuralgia, or of splenalgia. If one realizes the connection of this condition with abscess of the liver, one will not be misled by thinking that one has to deal with malaria.

The fever in hepatic suppuration is more frequently intermittent than remittent; the pulse is only moderately disturbed, its variations being disproportionate to those which are observed in connection with the temperature.

Intrathoracic Operations Performed With the Assistance of Sauerbruch's Chamber.—Mikulicz, in the *Revue de chirurgie*, for November 10, 1904, thinks that in view of his experiences and his study upon the cadaver, it is not always indispensable that the thorax should be extensively opened by a large temporary resection of the ribs in order to suture the heart. The opening of an intercostal space will often be all that is necessary. By cutting the intercostal muscles for half the length of this space, the sides of the wound can be held apart with the hands, or with a suitable retractor, sufficiently to enable one to operate within the thorax.

Simple intercostal thoracotomy between the third and seventh spaces may be practised with much economy of time. The closure of the thorax is made with tier suturing of the intercostals and the large muscles of the chest. Sauerbruch's chamber facilitates the removal of tumors from the chest wall and operations upon the diaphragm. By its aid the lungs become more accessible, for they can be readily reached over a large extent.

This chamber may possibly permit the surgical treatment of certain organic diseases of the heart, like the narrowing of the mitral valve, for example. Particular reference is made by the

author to the surgery of the thoracic portion of the œsophagus. If it is necessary to resect it there will be great difficulty in uniting the two ends on account of the rigidity of the tube.

If a resection of its lower portion is made the great cul de sac and the cardiac end of the stomach are drawn through the opening in the diaphragm and attachment made to the remaining portion of the œsophagus. In order to make resections of this portion of the tube, Mikulicz recommends an anterior incision in the sixth left intercostal space. He has operated only once on a human being in Sauerbruch's chamber, and under pressure. The case was one of cancer of the upper half of the thoracic œsophagus. The patient died from collapse during the operation. During the operation the lungs retained their normal volume and the respiratory movements remained regular.

Physiological and Physical Principles Involved in Intrathoracic Operations Performed in the Pneumatic Operating Chamber Invented by Sauerbruch.—Sauerbruch, in the *Revue de chirurgie*, for November 10, 1904, has made a study of the inconveniences and dangers which attend artificial respiration which may become necessary to combat operative pneumothorax, and proposes a method, applicable to human beings, which rests upon the principle of the constant maintenance of the difference of physiological pressure between that which is exerted within the bronchial tubes and that which is exerted within the pleural cavity. He makes use of a chamber in which the physiological lowering of the intrapleural pressure is obtained by aspiration of the air.

In experimenting upon animals the head of the animal remains outside the chamber and is separated from the latter by a rubber ball. Within this chamber one can make extensive resections of the thorax without causing serious trouble in the circulation or the respiration. The operator and his assistants can readily tolerate the conditions within the chamber.

Sauerbruch has constructed a large and a small chamber, the former differing from the latter in the fact that on the wall, opposite the side on which is the patient's head, is fitted a cylinder in which the abdomen and the lower limbs are introduced. This cylinder is hermetically closed at the level of the lower opening of the thorax and communicates with the external air. By this means the normal pressure is maintained in the pulmonary veins, while the pleural aspiration is diminished.

In a second method it was sought to obtain the difference in pressure, not by exerting less pressure upon the lungs, but by increasing the pressure within the lungs. This method resulted in producing troubles in the circulation and in the respiration which were not present in the first method.

In the course of his studies Sauerbruch observed that the hyperæmia which accompanies the collapse of the lungs plays an important part in the pathology of pneumothorax.

Official News.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the period from February 18 to February 25, 1905:

Smallpox—United States.			
Place.	Date.	Cases.	Deaths.
Florida—Jacksonville	Feb. 11-18	1	
Illinois—Chicago	Feb. 11-18	15	4
Illinois—Galesburg	Feb. 13-20	1	
Louisiana—New Orleans	Feb. 11-18	6	
Two imported.			
Massachusetts—Boston	Feb. 11-18	1	
Massachusetts—Lawrence	Feb. 5-18	5	
Massachusetts—Lawrence	Feb. 11-18	1	
Michigan—Detroit	Feb. 11-18	5	
Michigan—At 66 localities	Jan. 28-Feb. 4	4	Present.
Missouri—St. Louis	Feb. 11-18	28	6
Nebraska—Omaha	Feb. 11-18	13	
New York—New York	Feb. 11-18	1	1
Ohio—Toledo	Feb. 4-18	12	
Pennsylvania—Steelton	Feb. 11-18	1	
South Carolina—Camden	Feb. 11-18	1	
South Carolina—Charleston	Feb. 11-18	2	
South Carolina—Greenville	Feb. 4-11	5	2
Tennessee—Nashville	Feb. 11-18	7	
Wisconsin—Milwaukee	Jan. 21-Feb. 11	24	

Yellow Fever.			
Brazil—Rio de Janeiro	Jan. 8-29	16	3
Mexico—Merida	Feb. 5-11	1	
Panama—Panama	Jan. 1-Feb. 11	19	6
6 cases, 2 deaths from U. S. S. Boston.			

Smallpox—Foreign.			
Brazil—Bahia	Dec. 31-Jan. 21	2	
Brazil—Para	Jan. 1-31	66

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending February 22, 1905:

BLUE, R., Passed Assistant Surgeon. Detailed as member

of Revenue Cutter Service Retiring Board at San Francisco, Cal. February 16, 1905.

FOSTER, S. B., Acting Assistant Surgeon. Department letter of January 23, 1905, granting Acting Assistant Surgeon Foster leave of absence for twelve days, amended to read ten days from January 24th.

OAKLEY, J. H., Passed Assistant Surgeon. To proceed to Northport, Wash., for special temporary duty. February 21, 1905.

STIMPSON, W. G., Passed Assistant Surgeon. Detailed as member of Revenue Cutter Service Retiring Board at San Francisco, Cal. February 16, 1905.

WILLIAMS, L. L., Assistant Surgeon-General. Granted leave of absence for eight days from February 14th. February 16, 1905.

Board Convened.

Board convened to meet at San Francisco, Cal., February 25, 1905, for the physical examination of officers of the Revenue Cutter Service. Detail for the board—Passed Assistant Surgeon W. G. STIMPSON, chairman. Passed Assistant Surgeon J. M. Holt, recorder.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending February 25, 1905:
PAYNE, J. H., Passed Assistant Surgeon. Ordered to the *Pennsylvania*.

SCHWEIN, L. H., Acting Assistant Surgeon. Detached from the *Abarenda* and ordered home to await orders.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending February 25, 1905:

BIRMINGHAM, H. P., Major and Surgeon. Left the Chief Surgeon's Office, Department of Texas, on tour of inspection to Jackson Barracks and Fort St. Philip, La.

GIRARD, A. C., Colonel and Assistant Surgeon General. Leave of absence extended thirty days.

MORSE, A. W., First Lieutenant and Assistant Surgeon. Relieved from duty at Vancouver Barracks, Wash., and ordered to accompany the Nineteenth Infantry to Manila, P. I., where on arrival he will report for duty in the Division of the Philippines.

SHEPARD, JOHN L., First Lieutenant and Assistant Surgeon. Left from detached duty at Washington, D. C., on fifteen days' leave of absence.

STONE, JOHN H., First Lieutenant and Assistant Surgeon. Granted four months' leave of absence to take effect about April 1st, with permission to go beyond the sea.

The following named medical officers are relieved from duty in the Division of the Philippines, to take effect on the dates set opposite their respective names, or as soon thereafter as practicable, and will then proceed by the first available transport to San Francisco, Cal., and upon arrival will report by telegraph to the Military Secretary of the Army for further orders:

BOYER, P. L., First Lieutenant and Assistant Surgeon. May 12, 1905.

BROOKE, ROGER, JR., First Lieutenant and Assistant Surgeon. May 12, 1905.

HALL, JAMES F., First Lieutenant and Assistant Surgeon. May 26, 1905.

HALLORAN, P. S., First Lieutenant and Assistant Surgeon. May 12, 1905.

HEARD, GEORGE P., First Lieutenant and Assistant Surgeon. May 26, 1905.

KOERPER, C. E., First Lieutenant and Assistant Surgeon. May 12, 1905.

NELSON, KENT, First Lieutenant and Assistant Surgeon. May 26, 1905.

O'CONNOR, R. P., First Lieutenant and Assistant Surgeon. May 12, 1905.

PATTERSON, R. U., First Lieutenant and Assistant Surgeon. May 12, 1905.

PHALEN, JAMES M., First Lieutenant and Assistant Surgeon. May 26, 1905.

QUINTON, WILLIAM W., Captain and Assistant Surgeon. May 26, 1905.

RAGAN, CHARLES A., First Lieutenant and Assistant Surgeon. May 26, 1905.

RUFFNER, E. L., First Lieutenant and Assistant Surgeon. May 26, 1905.

WHITMORE, E. R., First Lieutenant and Assistant Surgeon. May 12, 1905.

WILSON, WILLIAM H., Captain and Assistant Surgeon. May 26, 1905.

WOODALL, WILLIAM P., First Lieutenant and Assistant Surgeon. May 26, 1905.

Births, Marriages and Deaths.

Born.

MUNDORFF.—In New York, on Friday, February 24th, to Dr. and Mrs. George T. Mundorff, a son.

Married.

BARSUMIAN—BEDFORD.—In New York, on Friday, February 17th, Dr. Hagopian G. Barsumian and Miss Jennie Bedford.

DARLING—LLEWELLYN.—In New York, on Saturday, February 18th, Dr. Samuel T. Darling and Miss Naunryrie A. Llewellyn.

GREEN—BRICKELL.—In Weldon, North Carolina, on Thursday, February 16th, Dr. Isaac E. Green and Miss Margaret Williamson Brickell.

HINMAN—TALLMADGE.—In Catskill, N. Y., on Tuesday, February 14th, Dr. Eugene E. Hinman and Miss Edna Tallmadge.

JACKSON—HEXTER.—In Philadelphia, on Wednesday, February 22nd, Dr. Joseph Maurice Jackson and Miss Stella Hexter.

PHILLIPS—BAGWELL.—In Baltimore, Maryland, on Wednesday, February 15th, Dr. Francis Murray Phillips and Miss Harriet Twyford Bagwell.

Died.

BUCHAN.—In Union Grove, Wisconsin, on Thursday, February 16th, Dr. Alfred Buchan, in the fifty-eighth year of his age.

CRISFIELD.—In Jacksonville, Florida, on Tuesday, February 21st, Dr. James E. Crisfield, of Dansville, N. Y.

GALE.—In Chicago, on Saturday, February 18th, Dr. John H. Gale, in the sixty-ninth year of his age.

GRANNISS.—In Saybrook, Connecticut, on Friday, February 17th, Dr. John H. Granniss, in the sixty-first year of his age.

GRIFFITHS.—In Brooklyn, N. Y., on Monday, February 20th, Dr. William Edward Griffiths, in the sixty-third year of his age.

HOUGHTON.—In New York, on Sunday, February 19th, Dr. Elihu Russell Houghton, in the forty-first year of his age.

HUNT.—In Charlestown, Massachusetts, on Thursday, February 16th, Dr. Israel T. Hunt, in the sixty-sixth year of his age.

PHELAN.—In Duluth, Minnesota, on Saturday, February 11th, Dr. Francis Norton Phelan.

QUIRK.—In Sayre, Pennsylvania, on Thursday, February 9th, Dr. Matthew Aloysius Quirk, in the thirty-second year of his age.

SENER.—In Middlesboro, Kentucky, on Wednesday, February 15th, Dr. D. W. C. Sener.

SHAW.—In Middletown, N. Y., on Wednesday, February 22nd, Dr. Mortimer Wright Shaw, of New York, in the thirty-eighth year of his age.

VAN DALSEN.—In Paterson, New Jersey, on Thursday, February 16th, Dr. Spencer Van Dalsen, in the fifty-third year of his age.

VAN RENSSLAER.—In Boston, Massachusetts, on Monday, February 13th, Dr. H. R. Van Rensselaer.

VIXTRUM.—In Colorado Springs, Colorado, on Thursday, February 9th, Dr. J. A. Vixtrum.

SUBCUTANEOUS INJURIES OF THE ABDOMINAL WALLS AND VISCERA.

By DANIEL N. EISENDRATH, A. B., M. D.,

CHICAGO.

In taking a retrospective view of abdominal surgery in the past twenty years one is struck by the fact that, comparatively speaking, the treatment of injuries of the abdominal viscera without external signs has progressed rather slowly.

The increased number of reports of both successful and unsuccessful cases shows that the interest of the profession has been aroused both in this country and abroad, especially during the past eight or nine years. Up to that time a patient who had been stabbed or shot, and who had some palpable evidence of injury in the shape of a wound of entrance, received far more attention than one who had often sustained graver and more frequently fatal injuries, but who perhaps had only a few abrasions on his abdomen.

The practitioner or surgeon, or both, were only too often content to make a diagnosis of "internal injuries" and calmly watch the patient succumb to a septic peritonitis from a perforated intestine or bladder. The same physician who urged immediate laparotomy for a ruptured extrauterine pregnancy on account of the rapidly increasing symptoms of anæmia from hæmorrhage into the free peritoneal cavity, would often sit apparently hopeless by the bedside of a man or woman who showed the same symptoms from the rupture of a spleen, or liver, or kidney, as the result of a crushing blow upon the abdomen, and not be aware of the fact that a laparotomy with extirpation of the spleen or the simple tamponade of a bleeding liver was even easier than the removal of a bleeding tube.

Ruptures of the abdominal viscera without external signs are more frequent than the combined number of gunshot and stab wounds of the same organs.

Of 362 cases of injury of the liver collected by

Eidler, in 1885, 50 per cent., or 184, were without external signs and the remainder was due to stab and bullet wounds. A similar ratio held true for injuries of the spleen.

Many lives could be saved every year if the diagnosis of a rupture of one of the abdominal viscera was made early enough, so that the question of surgical intervention might be discussed at a time when the percentage of chances of success was greatest. This is in the first six to twelve hours after the injury. As I will show, it is practically useless to make a diagnosis of a perforation of the bladder or intestine after the first twenty-four hours, or to hope to compensate for the tremendous hæmorrhage following a laceration of the spleen, liver, or kidney after the first twelve hours.

I trust that the reading of such papers as this will draw the attention of both surgeon and physician to this fertile field of diagnostic skill. Whenever a man or woman has fallen from a height, been kicked by a horse or human being over one of the abdominal regions, or thrown against a wagon pole or some other projecting object, or the trunk has been crushed, or some blunt missile has been thrown at him, do not fail to look for symptoms of a ruptured viscus, and give the patient at least the benefit of our latest observations in this direction. In many cases your watchfulness will be rewarded by the saving of a life which would have been lost without prompt surgical intervention.

When I am called to see a case with the history of one of the above modes of injury, my first thought is to consider which organ can have been injured. A practical division into hollow and solid viscera facilitates such a diagnosis and, by painstaking observation of the general and local conditions, a probable and often positive opinion can be formed, not only of whether any organ has been injured, but also of which particular one, so that the abdominal incision can be made as close as possible to the seat of injury.

Amongst the hollow viscera may be included, in the order of frequency of their injury, the small

and large intestine, urinary bladder, stomach, gall bladder, and ureters. The solid viscera, also given in the order of their frequency of injury, are the kidney, liver, spleen, and pancreas.

Ruptures of the kidney and intestine formed over 60 per cent. of 143 cases of all varieties collected by Makins and Neumann.

The reason for this is that the intestines have behind them the firm spinal column, and are separated from the abdominal wall in front only by the omentum, so that they are most frequently caught between the place where the abdomen is struck and the spinal column. Such a mechanism of injury occurs when the ileum or jejunum is crushed and torn, because the coils of this portion of the intestine are more mobile and are readily compressed against the firm spinal column. A second variety of injury of the small intestine and at times, although far more rarely, of the large intestine is a tearing off of the bowel say at the duodenojejunal flexure, or in the ascending or descending colon by a force which separates the bowel from its rather fixed point of attachment.

The reason why the kidney, like the intestine, is so frequently injured, has been variously explained. According to some, it is compressed by a crushing force between the rigid spinal column and the last two ribs; according to others, it is the action of the force upon a body full of liquid, which causes it to burst (Küster's hydrostatic theory). The spleen and liver are fairly well protected by the lower six or seven ribs. They lie in close contact with these bones, being separated from them by the diaphragm and lower borders of the lungs. A fall from a height, however, will allow the liver, by reason of its own weight, to be torn from its firm ligamentous attachment to the diaphragm. Similarly, a fall upon some blunt object, or a crush between two resistant bodies, as in being run over, or the compression of the lower part of the thorax, caused by running into a wagon pole or being struck by some object, as in one of my cases, where a monkey wrench was thrown at a boy or, as in another case, where a man was struck by a policeman, or a horse kick—all of these are liable to cause a rupture of the spleen or liver. The organ is caught between the wounding agent and the ribs lying behind it, as well as the spine, and so crushed.

The empty urinary bladder is seldom injured, because in the adult it lies well within the bony pelvic ring. In the child, however, a less degree of fullness than in the adult favors a rupture, as in a case to be spoken of, because the bladder in children lies only partly in the pelvis. In adults the bladder, when full, is most likely to tear at the

fundus. Such a rupture is often associated with fracture of the pelvis. It may be situated entirely in that portion of the bladder which is covered by peritonæum, thus allowing the urine to escape into the general peritoneal cavity, giving rise to the intraperitoneal variety of rupture. On the other hand, especially in fracture of the pelvic bones, it is torn at some point not covered by peritonæum, permitting the urine to escape into the pelvic cellular tissue, and even into the abdominal wall, as in my own case.

The gall bladder, ureter, and pancreas are seldom the seat of injury, because they are well protected by surrounding viscera.

What are the pathology and results of the rupture of the individual viscera? Only the capsules of the kidney, liver, and spleen may be torn and heal spontaneously without symptoms. If, however, a laceration of the parenchyma occurs, it may vary from a simple tear, extending deeply into the organ, to complete pulpification.

The immediate effect of these latter injuries is a more or less severe hæmorrhage, which in the case of the liver and spleen escapes into the free peritoneal cavity, and gives rise, as we shall see shortly, to dullness in the dependent parts, and to symptoms of acute anæmia. In 143 cases of death from rupture of the liver, hæmorrhage was the cause of death in 59. In the kidney injuries, the blood in the majority of cases escapes into the perirenal tissues, and along the ureter, causing hæmaturia. In a small number of cases the peritonæum in front of the kidney was torn, allowing the blood to flow into the general peritoneal cavity, and giving rise to the same group of symptoms as in rupture of the liver and spleen.

The hæmorrhage from the solid organs may cease spontaneously, and in the case of the extra-peritoneal kidney lacerations this blood will, in the majority of instances, be absorbed and the patient will recover. But when there has been a temporary stasis of bleeding in ruptures of the spleen and liver and intraperitoneal injuries of the kidney, the patient may have a recurrence of bleeding from dislodgement of the clot, or may succumb to a sepsis from infection of the large quantity of blood in the peritoneal cavity.

In the case of the hollow viscera, like the stomach, intestine, and bladder, the conditions are even less favorable than in the solid or parenchymatous viscera.

The chances of a walling off of the escaping intestinal contents or urine are very slight, and the mortality of non-operated cases is almost 95 per cent.; 11 out of 160 cases not operated upon recovered with formation of fæcal abscess.

In intraperitoneal rupture of the bladder, the

prognosis is fully as bad if the case is not operated upon.

When the urine escapes into the general peritoneal cavity, peritonitis develops within forty-eight hours. In extraperitoneal ruptures the loose pelvic cellular tissue becomes infected a little more slowly, but causes sepsis and death in the end.

In order to make a diagnosis of whether one of the abdominal structures has been injured, it is best to examine the case in a systematic manner, and I would suggest doing so by first asking the history.

First.—How did the accident occur? Was the patient crushed, run over, struck a blow over the abdomen, have something thrown at him; did he fall from a height upon his feet or buttocks?

Second.—Exactly what part of the abdomen received the main impact of the blow? If in the region above the umbilicus in front, suspect injury of the liver, spleen, kidney, gall bladder, stomach, and duodenojejunal flexure, or tears of the mesenteric vessels. If below the umbilicus in front, suspect the small and large intestine, urinary bladder, and ureters. If the main impact of the blow was received over the lumbar regions, examine for injuries of the kidneys.

Third.—What is the patient's general condition? Has it improved or grown worse since the time of the accident? The first effect in many cases of a blow upon the abdomen is great shock, with all of its typical symptoms. This primary shock is often not recovered from and continues up to the time the patient is seen by a medical man. If, with such a history of continuance of primary shock, with rapid, small pulse, great pallor of the skin and visible mucous membrane, restlessness, thirst, there are other signs of internal hæmorrhage, one should suspect that one of the solid viscera, like the spleen, the liver, or kidney, has been torn, and if there is no improvement in the patient's condition within six to eight hours from the time of injury, the chance for spontaneous amelioration of the symptoms is slight. In other cases the primary shock or primary syncope is recovered from by the time the patient is examined, and we must then depend upon the history of the injury, the local conditions which can be obtained by physical examination (see next subdivision), and a gradual increase in symptoms of anæmia, or of peritonitis for our diagnosis. This class of cases will be discussed more fully.

In a third class there has been apparently no primary shock at all, and we have simply the history of an injury, and the results to be obtained

by a careful local examination of the patient's abdomen, and observation of his pulse as to increase in rate, in order to make our diagnosis. It is this last class of cases to which we are called, with only the history of an injury, in which rupture of the abdominal viscera is so frequently overlooked until the symptoms of peritonitis or of internal hæmorrhage are so evident that surgical intervention is too often of no avail.

Fourth.—One should make a careful physical examination of the patient's abdomen, because this is one of the most valuable aids in making a diagnosis. This may be conducted in the systematic way of an ordinary physical examination, beginning with inspection of the abdomen.

INSPECTION.

(a.) One should look for abrasions, bruises, or the evidences of a traumatic hernia, all of which may aid us somewhat in determining over what portion of the abdomen the greatest amount of force acted. The history of the injury will aid us greatly, because in some cases the force acts in a circumscribed manner, as, for example, a man's or a horse's kick upon some one point of the abdomen, where it often leaves but slight traces. Similarly, the history of a more diffuse force, such as violence from a crushing between two cars, or between the axle of a wagon and a wheel, will aid us in determining whether a viscus at some distance from the abrasions or bruises which may be present in the case, has been injured. Following this examination of the skin, one should take the next step in the physical examination, that is,

(b.) Palpation of the abdomen. First, determine whether there has been a fracture of any of the ribs, because such fractures are often accompanied by ruptures of the spleen, liver, and kidney. Next determine whether there has been a fracture of any of the pelvic bones, especially in the region of the symphysis pubis, because they are often complicated by ruptures of the bladder and of the urethra. The next step in palpation is extremely valuable, namely, to find out where the greatest degree of tenderness exists, because this will often lead to the determination, especially in the early hours, as to whether a visceral injury has occurred, and is regarded as one of the most valuable signs by the majority of surgeons. A second extremely important symptom to be determined by palpation is one to which French and German surgeons attach great value, namely, the presence of a more or less localized rigidity of the abdominal wall, especially if it persists during a number of hours of observation of the case. Palpation will further aid, as in one of the

cases I will shortly describe, in determining whether a protrusion is due to a hernia or a blood clot.

After inspection and palpation of the abdomen, which may have yielded valuable evidence of injury, a third subdivision of this physical examination consists of careful percussion of the abdomen.

By this aid we can determine whether there is dullness present in the flanks and also whether there is any change in the area of dullness when the patient is turned upon his side. In some cases it may be very difficult to elicit any changes on account of the rigidity and pain.

In ruptures of the spleen and liver, as well as in those of the kidney, in which the blood has escaped into the general peritoneal cavity, dullness appears quite early in the dependent, and if the blood has not all clotted, the anterior border of the area will change according to the position of the patient just as in an ascites. In many cases there is also an increase in the size of the areas of dullness of the spleen and liver when these are torn. In extraperitoneal ruptures of the kidney, dullness extends much farther toward the front of the abdomen than under normal conditions.

In ruptures of the bladder the lower part of the abdomen will show distinctly increasing areas of dullness.

This sign I have found to be of great value in the diagnosis of the two cases of extraperitoneal rupture in which I operated.

After having made the examination in the order given above, consider some of the individual symptoms, such as vomiting, increasing tympanites, and rise in pulse rate; in other words, the symptoms of peritoneal irritation which are followed rapidly by those of a more or less extensive peritonitis.

Vomiting which continues for some hours after the injury points strongly to intestinal perforation. Increasing tympanites and a constant rise in the pulse rate are indicative of beginning peritonitis.

Hæmaturia with or without renal colic points strongly to rupture of the kidney or ureter, especially if it increases in severity. A constant desire to urinate without the ability to do so is characteristic of injury to the bladder. The test by which a certain amount of sterile fluid is injected into the bladder, and the same quantity is expected to return, if there is no perforation, is so apt to lead to wrong results that but little reliance can be placed upon it.

HOW SHALL WE TREAT THESE CASES?

If we have made a diagnosis of rupture of the intestine or urinary bladder, the sooner the patient

is laparotomized, the better the chances for recovery. The same holds true for ruptures of the spleen and liver. Left to themselves, over 80 per cent. of patients with spleen and liver injuries, 93 per cent. of those of the intestine, 89 per cent. of the extra and 98 per cent. of the intraperitoneal ruptures of the bladder, will die. The outlook for spontaneous recovery in laceration of the kidney is far better. About 65 per cent. of such patients will recover without operation.

Through earlier diagnosis and operation the percentage of recoveries is constantly increasing.

Up to 1890, 3 cases of rupture of the spleen had been operated in, with 100 cases. In an article written by me in 1902, the percentage of recovery in 50 collected cases was 56 per cent., or 28 cases. Of these 28, 27 had been operated in since 1895. I have been able to collect 110 cases of ruptured spleen which were operated in; 65 patients, or 59 per cent., recovered, and 45, or 41 per cent., died.

In 1896, Petry collected 36 cases of rupture of the intestine, in which laparotomy had been performed, with 52 per cent. of mortality. Since 1896 I have found reports of 50 cases, with 23 deaths (46 per cent.), and 27 recoveries (54 per cent.).

The same improvement holds true for ruptures of the liver. Up to the present time I have collected 46 cases, with 21 deaths (45 per cent.), and 25 recoveries (55 per cent.). The percentage of recoveries after intra and extraperitoneal bladder ruptures has increased in a similar proportion.

There can no longer be any question that surgical intervention is called for as soon as a diagnosis of rupture of abdominal viscera has been made. The only exception is in the treatment of ruptures of the kidney, where the results have been far better with the expectant treatment unless the symptoms indicated operative interference. Such symptoms, in the case of an intraperitoneal laceration of the kidney, cannot be distinguished from those of a rupture of the spleen or liver. In the case of an extraperitoneal rupture, the destruction of kidney substance may be so extensive as to involve one of the larger branches of the renal artery, under which circumstances the hæmorrhage would continue, giving rise to the symptoms of constantly increasing anæmia, and a nephrectomy would be indicated. At times, after the rupture of a kidney and the formation of a large retroperitoneal hæmatoma, the onset of temperature and other signs of sepsis will also lead to operative measures. The site of the incision should vary somewhat, depending to a great extent upon the diagnosis previously made of the

viscus which has been injured. If the symptoms are those of an internal hæmorrhage, and it is not possible to diagnosticate as to whether this comes from the spleen, liver, or kidney, or from a rupture of a mesenteric artery, it will be found best to make an incision in the median line above the umbilicus, evacuate the blood, which is usually found in the shape of large clots, as rapidly as possible, and after removal of as large a quantity as can be reached with convenience through the incision, a systematic search should be made, first of the right and left lobes of the liver, then the spleen, and, lastly, the hand should be inserted deep into the peritoneal cavity to determine whether there has been a laceration of the kidney, with hæmorrhage into the free peritoneal cavity. In the case of ruptures of the liver, the method of treatment consists either of suture, cauterization, or tamponade. In general, it will be found very difficult to insert sutures into the bleeding liver, and the best results usually follow tamponade.

The Paquelin cautery has also been tried at times to stop the bleeding, but as just stated firm pressure through tamponing with gauze will in almost every case check the hæmorrhage. If, after examination of the liver, this organ is found intact, the next viscus to be examined in the systematic search is the spleen. The majority of the successful cases of rupture of the spleen in which laparotomy was performed were treated by splenectomy. This is a perfectly safe and easy procedure, and consists in bringing the spleen forward into the abdominal incision and ligating its pedicle after transfixing it so as to prevent slipping of the ligature. Several successful cases of suture of the ruptured spleen and also of tamponade have been reported, but removal of the spleen seems the shortest and safest procedure. It is not followed by any ill results, since the other blood making organs seem to take up its function. In a number of the cases of splenectomy for ruptured spleen, glandular enlargement and a moderate increase in lymphocytes have occurred, but were only transient. If the spleen has been examined, and also found free of evidences of injury, search should be made in these cases of intraperitoneal hæmorrhage for injuries of the kidney in which the hæmorrhage occurs into the free peritoneal cavity. Such cases are best treated by making a second incision over the kidney, and either tamponing it or performing a nephrectomy. It was stated that the incision in cases of suspected intraperitoneal hæmorrhage from a ruptured spleen, liver, or kidney, should be made in the median line above the umbilicus.

This statement is subject to modification in this respect, that if there is strong suspicion of a rupture of the liver, the abdominal incision should be made at once along the right border of the right rectus muscle, and on the other hand, if there is sufficient evidence of a rupture of the spleen, the incision should be made along the left border of the left rectus, as these organs are far more accessible to these latter incisions. It must not be forgotten that ruptures of the viscera are frequently multiple, and this fact must not be lost sight of during the operation. In one of the splenectomy cases referred to below the bleeding did not cease after removal of the spleen, because there was a tear in the superior mesenteric artery.

In those cases in which we have evidences or suspicions, at least, of a rupture of the lower portion of the intestine, especially of the ileum and jejunum, or a laceration of the bladder, the best incision is one in the median line, extending upwards from the symphysis pubis. The peritoneal cavity should be opened at once, and systematic search made for a perforation of the intestine, beginning at the ileocæcal valve, and examining the bowel toward the duodenojejunal flexure. At the same time, the peritoneal surface of the bladder can be examined, and if no injury of this surface of the bladder or of any portion of the small intestine is found, the incision can be closed and search made for an extraperitoneal rupture of the bladder. If upon opening the extraperitoneal tissue above the pubis in such an operation, fluid is found in the cellular tissue around the bladder, it points strongly to an extraperitoneal rupture, and it will not be necessary to open the peritoneal cavity until this perforation has been disposed of. The best method of treatment for a perforation of the intestine or of the bladder is to suture them by means of a Lembert suture of fine silk, in two layers superimposed. In case the perforation involves the entire circumference of the bowel, or there is sufficient contusion to warrant a prognosis of gangrene of the bowel, a resection may be necessary. In the extraperitoneal ruptures of the bladder, if there has been considerable escape of urine into the pelvic cellular tissue, the best results can be obtained by suturing the perforation with a fine Lembert silk suture, and then inserting gauze drains around the bladder. When, as in the case about to be mentioned, there is a co-incident rupture of the urethra, the safest plan is to make an incision into the bladder, bring the edges to the surface, and insert a drain as in suprapubic cystotomy.

As was stated at the beginning of this article,

the treatment of ruptures of the abdominal viscera does not differ in any particular from that of other lesions of the same viscera, the chief question being one of early diagnosis. My own cases consist of two of rupture of the spleen, in both of which unfortunately diagnosis was made too late; one rupture of the kidney, and two of the bladder. I will give only a brief account of each case.

(To be concluded.)

AN UNUSUALLY SEVERE CASE OF ACUTE CHOREA SUCCESSFULLY TREATED WITH APOMORPHINE.*

By MONTROSE GRAHAM TULL, A. M., M. D.,

PHILADELPHIA.

In apology for presenting a remedy for a most troublesome affection, based upon my experience in a single case, I can only say the surrounding circumstances were so peculiarly definite, the clinical picture so distinct and perfect, the endorsement of the diagnosis by a specialist of high standing so valuable and the result so prompt, well defined and, above all, so satisfactory, that I feel justified in reporting the case at some length.

Elizabeth B., aged fifteen years, consulted me in the spring of 1904. She was an overdeveloped girl, presenting the physical appearance of a more mature woman, but was of neurotic stock; a maternal aunt having had chorea in an aggravated form when a girl. Her menstrual periods had appeared a year previous, but had not been regularly established. She had been sent to a boarding school in a distant city, and as a result of the general strain on her nervous system began to show signs of chorea. I at that time advised some changes in her school regimen, put her on the usual treatment of arsenic and iron, and advised an abundance of outdoor exercise. In spite of this she rapidly grew worse and had to be taken from school. On May 1, 1904, I was sent for to see her at her home and found the choreic and general symptoms much more pronounced. She soon was entirely unable to stand or walk. The condition rapidly degenerated into an acute mania, with thickened tongue, guttural, and unintelligible articulation, the lips being covered with a thick tenacious mucus. A confluent morbilliform rash extended from head to foot, covering the entire body, trunk, and extremities. She was soon a mass of bruises and had to be surrounded with bolsters to prevent her seriously injuring herself by contact with bedstead and walls. A trained nurse and her mother were with her constantly day and night. During this period I made use of all the accepted remedies, giving her at various times 10 grain doses of veronal, large

doses of strontium bromide, the three valerianates, opium by suppositories, and finally a pill containing morphine acetate, $\frac{1}{8}$ grain; camphor, 1 grain; English extract of hyoscyamus, 1 grain; and creosote, $\frac{1}{2}$ grain, every one, two, or three hours, *pro re nata*. This was in addition to arsenic in ascending doses, which had been exhibited from the beginning. After many days of this treatment, not only without a sign of improvement, but with a steady retrogression, I became alarmed for the patient's life, and called in my friend, Professor Charles S. Potts, who unhesitatingly pronounced it the most severe case of chorea that had ever come under his observation. He suggested rapidly increasing the arsenic to 16 drops, t. i. d., which was done at once with no apparent benefit. On the evening of the day following one of Professor Potts's visits we were all in despair, the mother insisting that something be done at least to give relief from the spasmodic movements which had continued, without intermission, for two weeks. I was ready to throw up my hands and confess myself completely baffled, when my somewhat familiar experience with apomorphine in alcoholic delirium occurred to me, and as a last resort, I concluded to try it in tentative doses. One fortieth of a grain of apomorphine was administered hypodermically with results as gratifying as they were surprising. Within probably three minutes the incessant motion had ceased, the muscles were relaxed, and the child slept peacefully and quietly. I then ordered $\frac{1}{20}$ grain by the mouth every three hours with the arsenic continued as before. At no time was there sign of nausea or vomiting. The result was all that could be desired; a steady, gradual improvement with no return of the severer symptoms. Ten days later the patient was able to go to Ocean City, N. J., where she spent the entire summer in good health.

The case seems to be of special value, in that the earlier treatment was reviewed and endorsed by a skilled expert, who at the same time confirmed the diagnosis and testified to the unusual severity of the attack.

It was extremely gratifying after all our efforts had proved abortive to find ourselves rewarded by an immediate success, from a remedy which, so far as our knowledge extended, had not previously been used in this disease.

This of course is but a single case, yet it has often seemed to me that the old maxim, that a chain can only be as strong as its weakest link, should be made to read that a chain ought to be, and should be made as strong, as its strongest link. Applying this to medicine would be equivalent to claiming that a clear, definite, unequivocal result in one case should be duplicated in all of the same type, and this would necessarily follow, were it not for our faulty application of remedial methods. I most sincerely trust, however, that in this instance, our results may be repeated and

* Read before the Philadelphia County Medical Society.

our conclusions confirmed by the experience of others along the same line.

Before leaving the subject, I may be pardoned for saying a word or two concerning the permanency and general reliability of apomorphine as a pharmaceutical product. My experience with it has been considerable, as in addition to its more common use in the delirium of acute alcoholism, with which you are doubtless familiar, I have for the past two years used it exclusively in the treatment of capillary bronchitis and the bronchial catarrhs of childhood with most satisfactory results.

Its physiological effects have manifested themselves in a marvelously short time. I have never seen it fail to turn water a bright green color when in aqueous solution. This result is so positive that I always forewarn the mother, that she may not be needlessly alarmed by the reaction.

With doses of one tenth of a grain, hypodermically, I have never failed to produce emesis within five minutes, and I have used it for this purpose in alcoholic cases many times during the past ten years.

In doses of one two hundredths, to one one hundred and fiftieth of a grain by the mouth to children, I have observed nothing more than a condition of general relaxation followed by very pronounced hypnosis, which is also very markedly present after the exhibition of large doses.

Its effects recall Professor Horatio C. Wood's characterization of *veratrum viride* as bleeding a man into his own vessels.

The pallor, cold sweat, and profound collapse seen after the ingestion of large doses are very alarming, yet I have learned to look upon them as upon a similar condition following the use of tobacco by one unaccustomed to it, decidedly more terrible in appearance than dangerous in reality. I believe that the general relaxed condition of the vascular system so relieves tension as to remove all chance of cardiac insufficiency. As a matter of fact I have always found the pulse full, regular, and soft, with deep and undisturbed respiration, notwithstanding the apparent great prostration.

In two cases which I have seen profuse bowel movements have followed the administration of one tenth of a grain hypodermically, but this appears to be exceptional.

I am quite sure that we have in apomorphine a much neglected and undervalued drug, most powerful in its therapeutical action, but in intelligent hands a perfectly safe agent. Taking everything into consideration I know of no remedy upon which I have learned to rely with more confi-

dence than upon this, and I now feel quite at a loss when it is not present in my hypodermic case.

THE EXAMINATION OF FÆCES.

By IRA S. WILE, M. D.,

NEW YORK.

Investigators have been led from the consideration of macroscopic appearance to ascertain the more intimate constitution of tissues and to analyze the various results of the mechanical and chemical functions of the individual. Each discovered fact has enriched our logical knowledge of the living processes. Particularly great advances have been made in the study of blood, urine, and structural alterations due to disease. Gastric analysis gives us valuable diagnostic aid. Perspiration, bile, saliva, cerebrospinal fluid leave much to be desired and are therefore receiving considerable attention. The fæces have received but moderate study by the general practitioner and as a result our knowledge of their clinical pathology is limited.

What can be learned from these residual products—what can be gleaned from this undigested, or better, unassimilated material? Theoretically we should ascertain the state and progress of intestinal digestion. The fæces bear the impress of various fluids other than those normal in the intestines, and so the theoretical condition of the intestine may be greatly masked.

Parasites may be detected; chemical changes occurring during health and disease may be studied; the products of disease and pathological alterations of stools may be investigated. While at the present time comparatively little is known of a subject so vast in its extent, the more frequent and careful examination of stools by medical men is necessary. Only by this means can advances in diagnosis be made and our knowledge of the clinical pathology of the fæces be increased.

In adults, idiosyncrasy and habit regulate the frequency of stools—from one or two within twenty-four hours to one in two or three days. In nurslings three, four or five stools in twenty-four hours are not abnormal. The frequency of stools is in direct relation to the amount of solids and fluids ingested. Constipation may thus result from fasting, diarrhœa from increased ingestion of liquids.

The amount of fæces depends on the quality as well as the quantity of food, i. e., on the amount of food unassimilated. Hence vegetable diet secures larger stools, 400 to 500 grammes, while mixed diet yields 120 to 200 grammes in twenty-four hours. In diarrhœas the increased quantity discharged is due to lack of absorption of fluids—as in cholera, where 5,000 grammes is not uncommon.

Normally firm, or mushy and formed, the stool

may vary from the hard, dry, fecal balls of obstipation to the watery stool of Asiatic cholera. Band-like scybala as a rule indicate an anteroposterior stenosis of the rectum.

In color one must differentiate the natural from the colors due to ingestion of certain foods or drugs. The normal bright brown to blackish brown, due to stercobilin, results from intermixture and interaction of bile and undigested food. Local variations of color may be recognized, as cherry pits, potato, portions of cereals, flocks of casein, etc. Stools of nurslings are colored by bile only. The intensity of color varies with the flow of bile. If the bile outflow is obstructed entirely, a dull gray stool presents itself. In the so called "bilious" stools the biliary color is unchanged, and the bright yellow, greenish yellow, or green results from rapid passage through the intestines, an increase of fluid in the bowel, or variation in reaction. According to Pettenkofer, the presence of unaltered bile pigment is always pathological. That drugs have been given in large enough doses may often be learned from the color of the stool:

Black is produced by iron, manganese, bismuth.

Blue, by long continued doses of iodides.

Green, by calomel.

Yellow, by santonin, senna, rhubarb.

Red, by hæmatoxylin.

Violet, by beta naphthol, salol.

In two robin egg blue stools of an infant suffering from enteritis I have found considerable indican.

The stool of a nursing child is normally of slightly sour odor, due to indol, skatol, and fatty acids. In slight infantile diarrheas the odor is similar to that of sebatic acid; in severe diarrhoea it is foul and putrid. In cholera and dysentery the odor is flat like that of semen. Gangrenous dysentery, carcinomatous or syphilitic ulcers of the rectum give a cadaveric stench. Blood and pus offer a mild stale odor. An ammoniacal odor usually arises from admixture of urine. This is very suggestive of a fistula somewhere along the urinary tract.

From reaction, Nothnagel concludes that little is to be learned. In children I believe it to be rather serviceable in determining the nature of the continuing fermentation. The stools of an adult are normally alkaline or neutral. The stools of children are alkaline save in severe diarrheas. In an examination of 563 stools of children under two years of age, 317 were found to be alkaline and 246 acid. The examinations were made while the infants were undergoing treatment for some form of summer diarrhoea. Medication was limited and the foods varied. From the observations of that time it appeared that the greener the color of the stool, the more likelihood of its alkalinity. The green acid stools were more constant in cases of fermentative

diarrhoea. This I believe to be the result of an increased flow of bile, yet insufficient to overcome the acidity due to fermentation.

Watery and mucous stools are self descriptive. Small amounts of mucus thoroughly mixed up in the fecal mass is the normal condition. If large mucous shreds are noticeable in the feces, enteritis is probable. Large, thick, tenacious masses bespeak colitis. If the mucus is white, glairy, spread on the surface of the stool, the inflammatory process is most probably in the rectum. Nothnagel's rules for localization of intestinal catarrh in chronic processes are of considerable value:

I. When the large intestine alone is involved, there is one full discharge in twenty-four hours and a recurrent diarrhoea.

II. When the small intestine alone is involved, movements are likely to be very sluggish.

III. When both are involved, a continuous diarrhoea results.

IV. Solid or semisolid stools, showing by microscope hyaline mucus, point to the upper part of the large intestine.

V. Presence of bile pigment (Gmelin's test) indicates catarrh of ileum and jejunum.

In the watery stools of acute intestinal catarrh, bile is usually not found. Virchow described "frog spawn" or "cooked sago" grains in watery stools. He believed them to be due to an excess of farinaceous food.

Fatty or alcoholic stools are offensive in odor, glistening, greasy, clayey whitish, containing needle-like crystals of fatty acids. Their appearance is due to an abundance of undigested fat. Occasionally by dissolving the fat in ether the remaining portion of the stool will assume a normal color showing that bile is really present, but concealed by the great excess of fat. Alcoholic stools are found in alcoholic poisoning, gout, enteritis of children, tuberculosis of the intestine, and, especially, chronic pancreatic disease. The fatty stools occur when bile is absent from the intestinal tract or when the intestinal mucous membrane and lymphatics are so altered as to be incapable of permitting absorption of the fatty materials. In pancreatic disease the presence of undigested muscle fibres is of importance.

Hæmorrhagic feces vary in appearance according to the site of the hæmorrhage. As a general rule, the nearer the anus the bleeding is the brighter the blood will appear at the anus. If scybala are merely covered with blood, the hæmorrhage is in the rectum or colon. If the blood is bright red and unchanged, the origin of the blood is the lower part of the rectum or anus—as from hæmorrhoids, fistula, or fissure. In thin stools, unmixed blood comes from the colon. Mixed, altered blood originates in the small intestine or stomach. Gastric

or duodenal hæmorrhage arising from ulcer or cancer gives the well-known "coffee grounds" appearance. Discovering minute amounts of blood in the fæces is of the utmost importance in the early diagnosis of cancer of the stomach or intestine. Occasionally a hæmorrhage of the ileum along with an active diarrhœa may make its exit bright red, as is not infrequent in cases of typhoid fever. Red blood corpuscles are seldom found unaltered. In most cases hæmatoidin pigment and masses of brown rhombic hæmatoidin crystals give evidence of the small hæmorrhage. If a firm stool is suggestively brown or black a test for blood is invaluable. Teichman's test is simple and satisfactory. Dry and powder a little of the fæces, place on a glass slide, add a crystal of salt and put on a cover slip. By capillarity run in two or three drops of glacial acetic acid. Heat the slide to just below boiling point. In a short time brown rhombic crystals of hæmin appear if blood is present. It should be borne in mind that ingestion of raw meat will cause small amounts of blood to appear in the fæces.

A purulent stool should be watched for whenever there is pus in the pelvis, as ulceration into the intestine may occur.

Gallstones of carbonate of calcium and cholestin are quite common and many cases of inexplicable dyspepsia are solved by careful examination of the stools. To search for stones, mix the stool thoroughly with water, strain carefully through a fine wire screen or several layers of cheese cloth. Wash residue again and strain once more. Examine the residue carefully. Enteroliths are to be distinguished from gallstones by softer consistency, lack of facets, and, if necessary, by chemical examination.

The microscope tells us a little about the state of digestion. By its use we may distinguish undigested animal and vegetable fragments and partially digested foods, as starches and fats. The particles are usually yellowish, stained by bile. To examine microscopically it is only necessary to place a small piece of fæces on a glass slide, moisten slightly with water, and cover with a thin glass cover slip. Mucus shreds are usually present, but not in large masses. Squamous epithelium is infrequent, while the columnar cells from the intestinal tract are always recognizable. Leucocytes are rarely seen, and when found, are laden with fatty globules. The presence of numerous white cells in a stool is highly suggestive of ulceration. Crystals of "coffin lid" or feathery triple phosphates are always present. Calcium oxalate and sulphate are generally present. The octahedral Charcot-Leyden crystals are occasionally found. Leichtenstein associates these with the existence of intestinal parasites. Along with eosinophilia of blood and the appearance

of numerous eosinophiles in the fæces, the finding of Charcot-Leyden crystals is even more suggestive of parasites. In jaundice of children and alcoholic poisoning, needlelike crystals of fatty acids are found in great number.

Bacteria constitute the bulk of the fæces' 30 per cent. of solid matter. Normally none has chemical interest save *B. coli communis*. Pathologically *B. typhosus*, *B. dysenteriae*, and *B. tuberculosis* are most important in this country. Moulds and yeasts are always present. *Amœbæ coli* are often demonstrable. While the typhoid bacillus may be found in the fæces, its diagnostic value to the physician is limited, as it rarely appears until the tenth or fourteenth day. Before Widal's test came into prominence, Lyonnet's process of demonstrating Eberth's bacillus was not a rarity to the laboratory examiner. The presence of tubercle bacilli in fæces does not necessarily imply infection of the intestine, as they may have had their origin in swallowed sputum. The bacillus tuberculosis may be demonstrated by ordinary methods (carbol fuchsin and methylene blue). The examination must extend over several days and include a number of slides from different portions of the same stool.

Of the larger parasites little need be said, as diagnosis is frequently made by the appearance of the animal itself or some portion of it in the stool. On the other hand, in obscure cases of anæmia, nervous depression, intestinal obstruction, chronic intestinal catarrhs, etc., careful examination of the fæces is frequently rewarded by finding small, round or oval shelled ova of the parasites causing the disturbance.

Most examinations for bacteria are outside of the laboratory facilities of physicians, and, therefore, may at present be given no comment.

In chemical examination most tests can be made with little apparatus. Albumin, normally absent in the stools of adults, appears in typhoid fever and some diarrheas. To test, mix fæces with water and a little acetic acid, filter several times, heat in test tube. An appearance of cloudiness is due to albumin. It is generally stated that the large cheesy masses in the fæces of infants consist of casein, while the smaller masses are made up of fats. It is more accurate to state that the masses, large or small contain both casein and fat. The proportions of fat and casein in the two vary very considerably. Peptone, seldom present in health, occurs in "pus cases," atrophic cirrhosis, and carcinoma of the liver. Urea is nominally present but its determination qualitatively is valueless, and quantitatively too complicated for clinical purposes.

Of the carbohydrates, starch and sugar are readily found. Boil fæces with water, filter, and test

filtrate with Legal's iodo-potassium iodide solution for starch or with Fehling's solution for sugar. Biliary acids may be demonstrated by Pettenkofer's methods. Urobilin is said to disappear in phosphorus poisoning, and its reappearance to be a favorable sign. Volatile fatty acids as formic, acetic, propionic, and butyric at present give but slight information when investigated. Unfortunately their determination is beyond the average clinical laboratory. The same is true of the gaseous constituents of the fæces, hydrogen, carbon dioxide, nitrogen, hydrogen sulphide, and the ptomaines, such as putrescine and cadaverine.

601 WEST ONE HUNDRED AND FORTY-EIGHTH STREET.

THE SO CALLED ATYPICAL FORMS OF GASTRIC ULCER.*

By J. KAUFMANN, M. D.,

NEW YORK,

ATTENDING PHYSICIAN TO THE GERMAN HOSPITAL.

In text books and monographs on gastric ulcer we find descriptions of atypical forms. When I was asked by the president of the Gastroenterological Association to speak on Atypical Forms at the "symposium" on Gastric Ulcer, the topic of this year's meeting, I was somewhat embarrassed in trying to determine what forms ought to be classed as atypical. What forms of gastric ulcer shall we consider as typical, what forms as atypical? The classification is in itself misleading.

If we consider as typical only those cases in which all the principal symptoms, severe pain, vomiting, hæmorrhage, hyperacidity, and hypersecretion are present, the clinical pictures which would have to be regarded as atypical become quite numerous. We really see all the cardinal symptoms combined in only a small percentage of cases, the great majority showing only some of these symptoms. In one group several cardinal symptoms may be combined, any one of which may be more pronounced than the others. In another group, we find only one cardinal symptom, pain, vomiting, or hæmorrhage as the case may be, while in a third group of cases none of the cardinal symptoms can be observed, until a sudden fatal hæmorrhage or perforation ends the patient's life.

Now, where shall we draw the line between the typical and the atypical forms? Shall we call atypical only those which show no cardinal symptoms at all—the so called "latent form" of ulcer? Shall we include as atypical those which show only one cardinal symptom, or shall we also add to

list those cases where we find two symptoms combined, and regard as typical only those in which all the symptoms are fully developed.

You will easily see how many combinations are possible here, and in the literature you will actually find a number of clinical pictures described under the heading of Atypical Forms.

Lebert, for instance, describes ten different varieties. Fenwick gives five forms, in which, as he says, "owing to the special predominance of some particular symptom, such as pain, vomiting, dyspepsia, hæmorrhage, or cachexia, the detection of the ulcer becomes a matter of more than ordinary difficulty."

He distinguishes the groups as follows: (1) The *gastralgic* form, the commonest variety, characterized chiefly by pain. (2) The *catarrhal* or *vomiting* form, where the principal symptom is prolonged and severe vomiting, without pain. (3) The *dyspeptic*, or "latent," form with only slight digestive disturbances. (4) The *hæmorrhagic* form, characterized by repeated attacks of hæmorrhage, to which the other symptoms are quite subordinate. (5) The *cachectic* form, in which the principal symptoms are emaciation and cachexia, appearing as a rule only after the disease has existed for a considerable time.

Fenwick, then, makes the predominance of one symptom a basis for describing atypical forms, while other authors describe different varieties, the classification depending on their personal experience and on the value attached to individual symptoms.

When carefully examined, such classifications are found to be very artificial and are more likely to confuse the diagnosis than to aid it.

Even in the so called "latent" form of gastric ulcer there are always some symptoms. The patients at times complain of dyspepsia, discomfort, and flatulency after meals, acidity, nausea, and some even have occasional attacks of vomiting. Only the cardinal symptoms, such as frequent vomiting, constantly recurring pain, etc., are missing, until finally perforation or fatal hæmorrhage proves that an ulcer was the cause of the dyspeptic symptoms.

We find similar conditions in other cases, with this difference, however, that the first hæmorrhage does not prove fatal. Then what at first appeared to be the "latent" form, or, according to another classification, the catarrhal form, is regarded as the hæmorrhagic form.

In other cases a period of slight symptoms is followed by one of severe pain, during which time the cases are classed as *gastralgic* forms. If, however, hæmorrhage occurs later, these cases are classed as *hæmorrhagic* forms; on the other hand, cases of the *catarrhal* or of the *gastralgic* form may, after a

* Read at the seventh annual meeting of the American Gastroenterological Association, Atlantic City.

period of years, develop into the condition described by Fenwick as the cachectic form.

Thus we see that not only the clinical pictures in different cases may vary greatly, but also that during the course of any one case a variety of clinical pictures may develop. In fact, the possible combinations of symptoms are so many that any number of atypical forms might be described.

I think, therefore, that we ought to do away entirely with the classification of forms of gastric ulcer as typical or atypical. In each case we have to deal with an ulcer that leads either to the development of symptoms few and vague, or to more pronounced and characteristic symptoms in manifold varieties. Each of those varieties is typical in its way, and a combination of symptoms that appears to one observer atypical may seem very typical to another who has learned how to interpret it correctly as caused by gastric ulcer. The less we classify the less shall we be apt to overlook the presence of an ulcer, in trying to fit each case to one form or another. We are confronted here with the same conditions as those connected with gallstone disease. For a long time the differentiation into regular and irregular gallstone attacks prevented the proper interpretation and correct diagnosis of cases which did not fit the typical or atypical forms discussed in text books. Since frequent operations for gallstones have taught us how vague and how few the symptoms are in many cases, and how manifold the combinations of symptoms may be, we have learned to disregard the old classification and to judge each case individually according to the symptoms it presents. We ought to follow the same course in dealing with gastric ulcer. If for practical purposes a classification is considered necessary, it ought to be as simple as possible. My teacher, Kussmaul, described in his lectures three forms: the catarrhal, the gastralgic, and the hæmorrhagic, at the same time pointing out that they might follow one another during the development of an individual case. It seems to me that these three forms, the names of which give their meanings, cover nearly all the clinical pictures one may find.

Far more important, however, than any classification is the fact, which has been proved by post mortem examinations as well as by experience gained at operations, that so called typical cases, i. e. cases with the well known triad of cardinal symptoms, pain, vomiting, hæmorrhage, form only a small minority. The majority of cases show clinical pictures described as atypical forms. That fact in itself shows how absurd it is to designate all those cases as atypical. If we make a positive diagnosis only in so called typical cases, we shall overlook many cases of ulcer and commit many errors. It is

my conviction that many more cases of ulcer are overlooked than diagnosticated.¹ This is certainly true of the majority of cases in the earlier period of their development. Cases which show the cardinal symptoms are nearly always far advanced. Hæmatemesis, for instance, occurs when the ulcer has penetrated into the deeper layers and has corroded a blood vessel.

If we desire to be more often successful in diagnosing gastric ulcer and in diagnostivating it early, we must not look for typical pictures, but must keep in mind the fact that the symptoms produced by gastric ulcer are often vague and few. We shall do well to follow Brinton, who in discussing the diagnosis of gastric ulcer advances the question: What is the *minimum* of probability that permits us to diagnosticate the presence of an ulcer?

We have to answer that question in each individual case, by weighing carefully each symptom, no matter how little pronounced, and on the other hand by considering each particular feature in the patient's history and examination. I cannot emphasize it too strongly that we must try to diagnosticate just those cases which are as a rule classed as atypical, and I am convinced that we are better fitted to accomplish that result when we are not prejudiced by a classification of forms as typical or atypical, to which we often vainly try to fit the individual history. All we have to remember is, that gastric ulcer may present a great variety of clinical pictures varying from the very obscure symptoms of plain dyspepsia up to the fully developed classical triad of cardinal symptoms. Since Brinton's day we have acquired a very important and valuable aid in diagnostivating such cases as show none or only one of the cardinal symptoms, that is, by the examination of the stomach contents. Although it must be admitted that hyperacidity is not a constant symptom in every case of gastric ulcer or at least not during the whole course of each case, it is nevertheless true that the presence of hyperacidity is the rule, its absence the exception. In doubtful cases, therefore, the finding of gastric hyperacidity suggests the presence of ulcer.

In fact, whenever gastric hyperacidity is persistent in spite of appropriate treatment and especially when the discomfort after meals is pronounced, when, instead of heartburn or pressure, the patient complains about gnawing or tearing sensations, the suspicion of an ulcer is justified. Keeping this fact in mind, we shall often be able to make a diagnosis, especially during the early stages of the disease, be-

¹ The statistics which have been presented before the association by Dr. Campbell Howard confirms this view. The records of some hospitals show a greater number of cases of gastric ulcer diagnosticated on the post mortem table than in the wards. When we remember that ulcer is a curable disease and does heal in most instances, such statistics are certainly significant.

fore the advent of severe pain or of hæmatemesis makes the diagnosis an easier matter.

Hyperacidity is not a disease, but always only a symptom, and in a great many cases a symptom of gastric ulcer. Many cases of gastric ulcer show no other symptoms than hyperacidity and the subjective complaints which we are accustomed to find connected with it.

More characteristic than hyperacidity is the finding of hypersecretion or gastrosuccorrhœa with gastric ulcer. Gastrosuccorrhœa is not a disease per se. The presence of gastric juice in the fasting stomach is always only a symptom and may develop whenever motor insufficiency and increased gastric secretion go together. It is met with during the course of various diseases of the stomach. Some authors say that we should not apply indiscriminately the term gastrosuccorrhœa to all cases where gastric juice is found in the fasting stomach. They maintain that we ought to distinguish between the cases where the presence of gastric juice in the fasting stomach is only a symptom, and another well defined group of cases for which they would reserve the term gastrosuccorrhœa as a disease per se. This sharply defined second group, the well known symptom complex of Reichmann's is, in contrast to the first, characterized by the presence of a combination of symptoms, i. e., pyrosis, vomiting, loss of flesh, and, most important of all, severe pains occurring after meals and during the night. This very combination of symptoms, which is asserted to be so typical as to warrant the diagnosis of gastrosuccorrhœa as a disease per se, is most characteristic of gastric ulcer. If you read the histories of cases of Reichmann's disease and, for the sake of argument, disregard the finding of gastric juice in the fasting stomach, I do not think that you will hesitate to diagnose gastric ulcer on the strength of the other symptoms. The finding of gastric juice in the fasting stomach does not change the picture, but gives additional strength to it, if its presence is correctly explained. The misinterpretation of this symptom is only one of the many mistakes that have been made since gastric contents have been analyzed to study gastric function. Functional disturbances which are really only symptoms have been stamped as diseases, and among those newly discovered diseases Reichmann's symptom complex takes a very prominent position.

So far as I know, no case has yet been reported where a post mortem examination has proved conclusively that Reichmann's symptom complex occurs without an ulcer. On the contrary, whenever an operation or an autopsy has afforded an opportunity to gain an anatomical basis, it has revealed ulcer or its sequelæ. We therefore shall do well to consider

as ulcer every case in which the combination of symptoms given by Reichmann is completely developed and in which severe gastric pain plays an important rôle. If we regard gastrosuccorrhœa as a symptom, it becomes a valuable aid in diagnosing certain cases of gastric ulcer. Whenever we find a patient suffering from gastric pains coming on regularly after meals and especially at night, with or without vomiting, the presence of acid fluid in the fasting stomach even in small quantities indicates ulcer of the stomach. In every one of my own cases of that kind, where the non-success of medical treatment made an operation advisable, the ulcer or its sequelæ could be demonstrated.

Therefore this symptom complex, which would otherwise be classed under the atypical forms, is in fact a very typical clinical picture of gastric ulcer. And so it is with other so called "atypical forms."

52 EAST FIFTY-EIGHTH STREET.

REMARKS ON THE RESULTS OF X RAY TREATMENT IN SEVERAL CASES OF CARCINOMA OF THE UTERUS.

By SINCLAIR TOUSEY, A. M., M. D.,

NEW YORK,

SURGEON TO ST. BARTHOLOMEW'S CLINIC.

The first case, the results in which I desire to discuss, is that of Mrs. P., who was brought to me March 18, 1903, by Dr. S. K. Royle. She was a large, handsome woman of 50 years, but young in looks and spirits. She had suffered for several years from an enormous fibroid tumor of the uterus, which had finally undergone carcinomatous degeneration. This was accompanied by a profuse sanguineous discharge of very offensive odor, and great loss of strength. In February, 1903, she had followed the advice of a number of physicians and had taken a private room at the Presbyterian Hospital for the purpose of having the growth removed. Under ether, however, it was found that the entire pelvis was one cancerous mass, and that anything like an attempt at extirpation would be immediately fatal. A small portion of the cervix was removed and a microscopical examination showed the growth to be carcinoma.

A few days later she left the hospital, her friends being led to expect that she would live only about six weeks. Instead of this, however, Dr. Royle brought her to my office for x ray treatment. At first she had to come in a coach with her nurse, the doctor, her mother, and husband. She was very weak and miserable, and it would take an hour to give her the few minutes' actual treatment and get her back into the carriage again. Then again she was not able to keep her appointments; she might have one for Tuesday and not be able to come until Saturday. Meanwhile, she was having very severe hæmorrhages, and these the doctor continued to treat by intra-uterine and vaginal injections of a very weak

formalin solution. The abdomen was distended by the tumor, giving almost the appearance of the completion of gestation. There were very painful and somewhat tender areas corresponding to the position of the broad ligaments. The vaginal portion of the uterus was cartilaginous to the touch, as were also the anterior vaginal wall, the urethra, and the entire fornix. There was a profuse bloody discharge with offensive odor.

The treatment consisted in allowing the x ray to shine through the uncovered abdominal wall, and also through a Nott's speculum—which has a duck bill blade posteriorly and two divergent blades anteriorly—and in the application of high frequency currents over the two painful areas. The intensity and the quality of the radiation from an x ray tube are subject to myriad variations. In the manipulation of the apparatus, either to produce a perfect radiograph or to secure a beneficial effect in any case, the thickness of tissue to be penetrated and many other factors are to be considered. Experience will enable one to accomplish the result, but the following details may serve as a rough guide:

The current was from the hundred and ten volt direct current of the incandescent lighting supply. A liquid interrupter of the Simon's type was used. In this the current has to pass from a lead electrode through dilute sulphuric acid—one part, to six parts of water—through pin holes in a tough porcelain beaker, and through dilute sulphuric acid in a large outer jar to another lead electrode. In passing through this, the current encounters enormous resistance and is reduced to seven amperes or less. Then, again, as soon as the current begins to flow, bubbles of gas are formed by electrolysis, which block up the pin holes in the inner beaker and arrest the flow of the current. The bubbles of gas immediately rise to the surface and the current begins to flow; more bubbles are then formed and the current is checked. In this way the current is interrupted something like ten thousand times a minute. These ten thousand successive currents, all flowing in the same direction, pass through a primary coil of about a hundred feet of heavy copper wire, carefully insulated, and each successive current causes a wave of induced electricity in the secondary coil containing a hundred thousand feet of insulated wire which surrounds—but which has no connection with—the primary coil. It is by connecting the x ray tube with the two poles of the secondary coil that the x ray is produced. It is not necessary to detail the different properties of the "make" and "break" currents. The coil which was used in treating this case was a Wappler eight inch coil, and the tube was a forty centimetre Gundelach tube, and a rheostat was used to cut the current down to about four and a half amperes. With the tube disconnected this strength of current gave about a six inch spark. The vacuum in the tube was adjusted for each treatment to correspond with an internal resistance of about two and a half inches, and a penetration of two or three layers in the author's radiometer, each layer consisting of lead foil weighing an ounce to the hundred square inches.

The distance was nine inches from the anode of the tube to the nearest surface of the patient, and the time of exposure was about five minutes over the abdomen and five minutes in the vagina.

The high frequency currents as used in this particular case were taken directly from one pole of the x ray coil by means of an insulated cord passing from the coil to an insulated handle by which the operator held a glass vacuum electrode, which was placed in contact with the skin. When in operation this tube is filled with ten thousand waves a minute of ultraviolet and violet light passing into the patient's tissues and disappearing. A certain amount of ozone is produced, and some of this is carried in by the current, while as some remains upon the surface, its odor may be detected on the following day. This is the simplest form of high frequency apparatus, but it is not so effective nor so agreeable in application as some of the forms which have come into use since this particular patient was treated. The first result of the treatment was the very prompt disappearance of pain. Next to go were the discharge and the odor. Her doctor was under the impression that a little general disturbance noted was due to the elimination of morbid products disintegrated by the first two or three treatments, but this seems problematical. At all events, after the first few treatments she began to gain wonderfully in health and strength, and the last few weeks that she was coming to me she hopped onto a street car all alone; as fine a looking dowager as you would care to see. Generally she had a box of fruit or cake for a sick friend, whom she would visit after leaving my office. She used to say that she would rather have one of those treatments than go to a matinee. The last time I saw her was on August 6, 1903, four and a half months after beginning treatment. The fibroid had diminished one half in size, and she had been taking in her clothes about two inches every two weeks. There had been scarcely any change in the cervix and vagina. The discharge, odor, pain, and weakness were a thing of the past. At this time I transferred the case back to her physician, Dr Royle, who continued x ray treatment, and under whose care she did very well indeed until about a year from the time that x ray treatment was begun. She then developed serious gastric disturbance which seemed to Dr. Royle and to a consulting stomach specialist not to be of a cancerous nature. Then, the family becoming anxious about her, a change was made from Dr. Royle, who had given her very faithful attention all this time, and another physician was called in. The patient sank very rapidly and died March 20, 1904.

Reviewing the case I am confident that this woman's life was prolonged for a year by the x ray, and during almost all that time she was well and happy.

Another case was that of Mrs. M., a patient of Dr. Hill. She was about fifty years old and for a number of years had had menorrhagia, for which she was curetted about ten years before, and later, about six months before, a vaginal hysterectomy

was performed for a condition of adenocarcinoma. When she came to me, October 13, 1903, there was an indurated and congested mass at the upper extremity of the vagina, looking like a part of the cervix. She had never recovered her strength after the operation. The treatment consisted in allowing the x ray to shine through the abdominal wall and also applying it directly to the vaginal fornix by means of Cossar's x ray tube. This is a tube in which there is a prolongation directly opposite the anode, through which the x ray passes, and which may be introduced into the vagina or other cavity. The entire x ray tube is constructed of lead glass, opaque to the x ray, except at the extremity of the intravaginal prolongation. This enables one to apply the x ray at the exact spot which it is desired to influence even in these internal cases. Flexible, but very heavily insulated conducting cords are a necessity, as the tube is held in the hand during this application. The application over the abdomen was with a forty centimetre tube of medium vacuum and a current of about four amperes, and lasted about five minutes at a distance of nine inches from the anode. The application in the vagina was with a current of about three amperes, and lasted about three minutes. High frequency currents were also applied over the abdomen and up and down the spine principally as a tonic. For this purpose a vacuum electrode was connected directly with one pole of the eight inch x ray coil and applied by means of an insulated handle. No connection was made with the other pole of the coil. The current was a mild one of about two amperes, and the application lasted about ten minutes. Treatment was begun October 31, 1903, and was given an average of once a week until December 3, 1903. The effects were diminution of pain and very marked decrease in the amount of discharge, but the patient's strength steadily failed and at the last date mentioned it became evident that the exertion of coming to the office for treatment was more than counteracting the benefit received; the x ray was therefore discontinued. She subsequently failed rapidly and died about two months later. In this case the symptoms were relieved, but the disease had advanced too far for any line of treatment to materially prolong life.

Another case which I have seen from time to time, is that of an Armenian woman under treatment by the house surgeon in Dr. C. D. Adam's gynecological service at St. Bartholomew's Clinic. The discharge and the size of the tumor have been kept down, the patient's general condition has improved, and a condition almost like that of health has been maintained for almost a year. Treatment has been through the abdominal wall and through a vaginal speculum. Mild applications have been made twice a week.

Another case is that of Mrs. H., a patient of Dr. Hill. She is a delicate little woman about 45 years old, who had been sick and miserable for a year, and who was only recently subjected to an examination, which showed that the cervix uteri formed a large fungating mass, and that there was a neighboring ulceration of the vaginal

wall from contact with the growth. She had been sick in bed many months, and the local conditions seemed to preclude the possibility of a complete cure by an operation, even if she survived it. She was accordingly brought to my office for x ray treatment, first for its effect in checking hæmorrhage and discharge; second, for its effect of destroying outlying cancer cells and rendering an operation a little more likely to be of lasting benefit, and, finally, for the tonic effect upon the system which would enable her to stand the shock of an operation. Treatment was begun March 30, 1904, and consisted in allowing the x ray from a 50 centimetre heavy anode Müller tube to shine through the abdominal wall, and also from a Cossar's tube in the vagina.

The tube used over the abdomen was of a low degree of vacuum and the strength of current about four amperes, distance about eight inches, and time of exposure five minutes. Ten treatments were given during the next month and a half, and then my suggestion that she could stand an operation was acted upon and a vaginal hysterectomy performed by Dr. Cleveland on May 18, 1904. The patient was very slow in regaining her strength after the operation, and there was a great deal of discharge. Finally, on July 12, 1904, she was able to come to the office again for x ray treatment. Her strength was at once improved and the discharge practically stopped. She is still under treatment, and the skin of the abdomen through which alone the applications are now made is quite tanned. High frequency currents have been applied by means of a D'Arsonval transformer. Of late she has been losing weight, however, and of course the ultimate outlook is unfavorable.

Another case is that of Mrs. M., referred to me by Dr. Cleveland, who had performed an abdominal hysterectomy for carcinoma in December, 1903. A recurrence was discovered in April, 1904, and she was sent to my office for treatment June 24, 1904. The patient is 45 years of age and weighs 150 pounds. At the time she came to me there was a considerable discharge of blood and pus, and the speculum showed an ulcerated surface of considerable extent in the scar at the vaginal fornix. The patient has an umbilical hernia about the size of a lemon, which is easily reduced. There was considerable abdominal pain and difficulty in regulating the bowels. In treating her the x ray has been allowed to shine through the abdominal wall from a Müller heavy anode 50 centimetre tube with a raising and lowering device, and in which the vacuum has been reduced to a resistance equal to a two inch spark and a penetration of two layers of lead foil weighing an ounce to the hundred square inches as used in my radiometer. The abdomen has been compressed by the author's board compressor. This is a board $\frac{1}{8}$ of an inch thick and 9 by 18 inches in extent, strapped tightly across the abdomen and used in taking pictures through the abdomen and in the treatment of internal organs. It is effective in consequence of reducing the thickness of the tissues through which the rays must pass, in enabling us therefore to get the tube

nearer the photographic plate or to the diseased organ, as the case may be. Then, again, it has seemed to me that the skin is markedly protected from the action of the ray, while the deep action of the photochemical rays is not in the least affected. This transmission of the photochemical rays has been demonstrated over and over in radiography as of the kidney for stone, and in treatment the skin has remained unaffected while the curative effect has been produced. The author is aware that this is a step toward the admission of the protective influence of aluminum screens and the like, but of course nothing that is transparent to the x ray will prevent dermatitis from exposures which are too long, too strong, or too frequent. The anode of the tube was sometimes 7 inches and sometimes 8 inches from the surface of the abdomen and the current was from a 12 inch Wappler coil, with a Simon's electrolytic interrupter, of a strength of $4\frac{1}{2}$ amperes. The duration of the application has been four minutes. The second part of each treatment has been the application of the x ray from the same tube, which was enveloped in a Friedlander shield, through a vaginal speculum for four minutes. The vacuum, strength of current and time of application were the same as for the abdominal application. The distance was 9 inches from the anode to the vulvar orifice. For a number of weeks the patient came twice a week, and the discharge ceased entirely and the intestinal trouble came to an end. No other local treatment has been used, since the case came under my care. Her general health and strength became normal. On removing the speculum it would be found absolutely clean and dry. After about six weeks' treatment the inconvenience and expense of the journey from the patient's house in Bridgeport, Conn., caused her to cut the treatment down to one a week, and now there is developing a small amount of mouse colored discharge, which is just enough to show on the speculum. After ten weeks' treatment no redness of the skin of the abdomen is perceptible, but some tanning of the perinæum and vulva is present.

The cases described are not selected as an argument in favor of the x ray in the treatment of inoperable or recurrent carcinoma of the uterus, but rather as showing fairly what may be expected from it in the various stages and types of the disease. I cannot too strongly recommend the adoption of the treatment at any stage before the recurrent cancer has too far sapped the patient's vitality.

103 WEST SEVENTY-SIXTH STREET.

The American Laryngological, Rhinological, and Otolological Society.—The eleventh annual meeting of this society will be held under the presidency of Dr. Frederic C. Cobb, at Boston, on Monday, Tuesday, and Wednesday, June 5th, 6th, and 7th. Physicians are cordially invited to attend the meeting and take an active interest in the papers and discussions.

A UNIQUE CASE OF APPENDICITIS IN A CHILD AGED FOURTEEN MONTHS.*

By LARKIN W. GLAZEBROOK, M. D.,

WASHINGTON, D. C.,

CORONER'S SURGEON, DISTRICT OF COLUMBIA; ATTENDING PHYSICIAN, WASHINGTON CITY ORPHAN ASYLUM, ETC.

On December 19, 1905, at 10 a. m., A. H. H., 14 months of age, while playing with several other children around a room, was noticed by the attendant as being ill. The child was markedly cyanotic and was having a severe rigor. She was at once taken from the floor, and it was noted that the child cried with pain on motion. The nurse at once administered ten drops of whiskey in water; in a few minutes the patient was comfortable, falling off to sleep in the nurse's lap. At that time the child was still pale and was breathing rapidly. The patient was put to bed and rested quietly until 12 m. At that hour the child awoke, crying with pain, which appeared to be situated in the lower right chest. Pallor was still marked, with short rapid breathing. At that time the nurse realized that the child was very ill, and suspecting pneumonia, telephoned for me. As I was engaged with another case Dr. E. L. Mason was called. He arrived about 1 p. m. At that time the child was in a semicomatose condition, with all the objective symptoms of pneumonia. I arrived a few minutes later and noted the same general appearance of the patient; before I was able to examine the patient, the little one died. Upon inspection and percussion I could make out nothing abnormal.

Previous History.—Father and mother apparently healthy people; several other young children. Six months before father had died of some acute disease. The mother was unable to care for this young child and secured its admission into the Washington City Orphan Asylum. Upon admission, the child was found to be in a healthy condition, and subsequently showed no ill effects of bottle feeding. The mother of the child, since her husband's death, had worn crape. As already stated, the child thrived upon the change of diet. At times, however, since its admission, it had had attacks of "wind colic," which had promptly responded to ordinary home remedies. My attention had never been called to this patient, until its last illness.

Necropsy.—December 20, 1904. Rigor mortis slight. General appearance, anemic. Nutrition fair. Abdomen not distended. As soon as abdomen was opened, my attention was called to the picture that presented itself. The large omentum, fan shaped, was seen to be adherent to the vermiform appendix, midway between the cæcum and its tip. This anastomosis was very firm, and appeared to be of several months' duration. As a result of some contraction of the omentum, the appendix had been drawn upwards; at the apex, the omental adhesion was found. The distal end of the appendix was free and not adherent. The only evidence of adhesions was at the omental attachment mentioned. To the left and posterior to this point about one drachm of green pus was found, which was escaping from a small perforation of the appendix. The

* Specimen and paper presented to the Clinico-Pathological Society.

appendix was then removed with a portion of the fan shaped omentum.

The other organs were found to be in a normal condition; the lungs in no way involved. The removed specimen was then carefully examined. A small round mass, about the size of a number 8 bird shot, and of the same consistence was felt three eighths of an inch above the tip of the appendix. Upon opening the appendix, I found this object to be the round head of an ordinary black mourning pin; at the omental attachment, where the rupture had been noted, I found the point of the pin (A). Immediately around the seat of the rupture, the parts were gangrenous. The accompanying drawing is of about the size of the specimen removed.

Besides the interesting features of this unique specimen, there are several other points which may be of interest.

The mother of the child was disposed to blame the institution for the condition found. Upon inquiry I found that no attendant at the institution was permitted to wear black, and that no black pins were ever used, especially the round head, mourning pins. The child had been an inmate for only two months. This fact, in connection with the dense band of adhesions, convinced me that the foreign body had no doubt been swallowed by the child while feeding from its mother's breast, prior to its admission. Either before or subsequent to this time the original puncture of the appendix occurred, followed by a simple local inflammation ("the conservatism of Nature"), resulting in the anastomosis noted.

The last illness lasted about three and one half hours, dating no doubt from the last rupture of the gangrenous appendix. The symptoms of this short illness were those usually met with in surgical shock. The subject of foreign bodies in the ap-

pendix has always been one of great interest to me. In 1,000 autopsies, done during the last twelve years, I have found only two other cases (fæcal concretions excepted). In neither of these two cases was death due to the foreign body, but to some other acute condition. In neither was there any apparent inflammatory condition of this part.

In conclusion, I wish to verify, as a result of my experience, the statement recently made by Vallée, who has found in 75 per cent. of autopsies upon children the cæcum on a plane above the anterior superior spines. The appendix, therefore, was somewhat higher than is seen in adults. It is, therefore, easy to understand why in many cases pain may be experienced at or near the diaphragmatic pleura.

2022 P STREET, N. W.

A CLASSIFICATION FOR CASES OF PULMONARY TUBERCULOSIS AND PHTHISIS.*

By KARL VON RUCK, B. S., M. D.,
ASHEVILLE, N. C.

The committee on nomenclature of the American Climatological Association recommended the following classification of cases, and of results of treatment, in pulmonary tuberculosis in their report of May 12, 1903:

SUGGESTED CLASSIFICATION FOR CASES OF PULMONARY TUBERCULOSIS.

Incipient. Slight physical and subjective signs, with history indicative of pulmonary tuberculosis. Sputa, if present, without bacilli.

First stage. Definite physical signs of localized infiltration; total involvement less than half a lobe, whether at one or more points; cough and expectoration with bacilli; constitutional symptoms slight. (In disseminated cases expectoration and bacilli may be absent with constitutional symptoms more severe.)

Second stage. Infiltration of single or multiple areas approaching or equal in amount to one lobe; or smaller areas in stage of softening; cough and expectoration with bacilli; constitutional symptoms, severe.

Third stage. Infiltration in excess of one lobe or, if less, in stage of well developed excavation; more severe constitutional symptoms.

CLASSIFICATION OF RESULTS OF TREATMENT.

Progressive. All essential symptoms and signs continue unabated.

Quiescent. Constitutional symptoms slight, or entirely absent; physical signs improved or unchanged; cough and expectoration with bacilli still present.

Arrested. Absence of constitutional symptoms; expectoration and bacilli still present; physical signs may or may not persist; foregoing to have existed for at least three months.

Apparently cured. All constitutional symptoms and expectoration with bacilli absent for a period of three months.

* Read before the American Climatological Association, Philadelphia, June 4, 1904.

Cured. All constitutional symptoms and expectoration with bacilli absent for a period of two years under ordinary conditions of life.

In this classification the committee fully recognized the necessary shortcomings of all classifications, but expects from its adoption a mutual agreement in the use of terms, by which something approaching harmony will be attained in records and reports by the members of the association. By a motion carried, upon its receipt by the association, a copy of the report was submitted to members with requests for opinions upon the same.

The attainment of the object which the association seeks in securing uniformity in classification appears to me of the greatest importance for every student of pulmonary tuberculosis, and an agreement in regard to it is to-day more necessary than ever in the light of the activity shown in every civilized country to combat this disease.

When only one or a few cases are the subject of a report, it is possible to add sufficient details, that enable an approximate estimation of their clinical features. In larger series of cases this is less feasible, and for purposes of prognosis in certain stages, for judging the value of, and for comparison of therapeutic measures, it is essential that large numbers of cases be brought together in certain groups corresponding clinically as nearly as possible. The natural desire to make such a classification concise, in order to avoid confusion, has governed most authors in the past, and is also apparent in the one under consideration; but no matter whether the basis for the classifications was purely a clinical one, or one that depended chiefly upon physical signs, all such concise methods have been found deficient, because it is impossible to bring the phases and stages of a disease, having such complex anatomical alterations and so varied a clinical course as phthisis is acknowledged to have, under two, three, or four comprehensive groups that have approximate uniformity in local alterations, in intensity of degree of constitutional impairment, or in their prospective future course.

Prior to the discovery of auscultation, phthisis was divided as a rule into three stages, an early or beginning stage, a middle or confirmed stage, and a last or terminal stage, all of which depended on the degree of constitutional impairment and intensity of existing symptoms. Such a classification was used by Andral (1) and by Bayle (2), the latter adding also a prephthisical stage, which he held to exist before the appearance of clinical symptoms, and in which the local alterations had

not assumed a sufficient extent or degree to produce them.

Although Laennec (3) introduced a division in which the anatomical lesions as shown by the physical signs were the chief feature, the clinical manifestations as the chief element of division have, nevertheless, been considered as most important by many authors since his time. Thus Grancher (4), in 1890, still adhered to Bayle's division, especially emphasizing the prephthisical stage, which would properly correspond to one of pure tuberculosis of the lung before the advent of phthisis proper.

Penzoldt (5) also recognizes clinical forms by dividing them into beginning, progressive, and stationary. Prior (6) divides his stages into incipient, confirmed, and consummate, while Musser (7) adopts a clinical basis for his divisions of acute, pneumonic, and chronic ulcerative forms.

West (8) says that not the anatomical lesions as determined by physical signs, but the constitutional and clinical conditions are of importance for prognosis, and upon the latter basis differentiates between an acute, subacute, and chronic course.

Cornet (9) distinguishes in three stages the customary clinical division, incipient, softening, advanced, according to the severity of symptoms.

Adhering to Laennec's, we find classifications which attempt to combine to a greater or less degree the clinical symptoms with the physical signs. Such classifications as those of Sir James Clark (10), of Stokes (11), and of Louis (12).

The more, however, the prognostic features were deemed essential, the more it became necessary to make more stages, or to make subdivisions, and among more recent authors we find Meissen (13) introducing a prephthisical, or what he calls his prophylactic stage, and adding a final decidedly hectic or hopelessly advanced stage to the customary three, with subdivisions for each according to the presence or absence of fever. A similar classification is that of Schroeder and Mennes (14).

Delafield (15) finds himself obliged to make four great clinical divisions, and to introduce seven subvarieties for the chronic miliary form of tuberculosis, according to the anatomical lesions and associated symptoms.

A. L. Loomis (16) made two large clinical divisions between acute and chronic forms, with an anatomical basis for three subdivisions of chronic phthisis; the pneumonic, the disseminated, and the fibrous, and he further divided each of these into early and advanced stages.

Percy Kidd (17) has five subdivisions for

chronic phthisis, according to the mode of onset of the disease, and three subdivisions for the acute forms. More simple again are the classifications of Strümpell (18) with three stages, incipient, cavernous, and disseminated.

Latham (19) distinguishes between two chronic and three acute forms, upon an anatomical basis, and clinically between the early and advanced stages of chronic phthisis in which he takes into consideration the existing physical signs.

Carrington (20), of the Fort Stanton Sanatorium, has clearly the clinical side in view when he makes his classifications good, bad, and very bad, while at the same time he seeks to establish a correspondence between these classes and three respective stages based upon physical signs.

On the other hand, many authors have ignored the clinical features almost entirely, some absolutely, basing their classification upon the anatomical lesions, as inferred by physical examination of the chest.

To these belong Lebert (21), Flint (22), (who simply distinguishes two stages, one before and one after excavation). Eichhorst (23), Brehmer (24), Hillier (25), and others.

Finally we have a number of those who believe that the extent of the area of lung involved should be the exclusive basis for classification, the clinical features being added as existing in the individual case.

The chief exponent of this basis for classification is Turban (26), and his method has found numerous adherents, especially in Germany. Kroeniger (27), however, had already made such a classification in a report of a large series of cases in 1895. Weicker (28), A. Möller (29), and a number of other directors of both public and private sanatoria follow Turban in their reports.

Turban limits his first stage to involvement of one whole or two half lobes, with moderate percussion dullness, auscultation showing medium sized râles. His second stage includes involvement of greater area not exceeding that of two lobes, or severer cases with only one lobe involved. His third stage comprises all cases exceeding the second stage.

A. Fränkel (30) prefers a similar division in use by the German Imperial Health Bureau, also of three stages.

First stage.—Light cases of the disease limited to a small and circumscribed area, especially the apex, and not extending below the clavicle in front, and the spine of the scapula behind, with or without râles, but not showing consonant râles.

Second stage.—Cases in which the local process exceeds in extent that of the first stage, but is less than in the third stage.

Third stage.—Consolidation of an entire lobe or of several lobes, or evidence of cavity.

Dr. Bowditch (31) also takes into consideration the extent of area involved at least in his first two stages, while the clinical features are also recognized. In his fourth report of the State sanitarium, Rutland, Mass., he gives the following division:

Incipient stage.—Physical signs confined to one or both apices, constitutional symptoms slight.

Marked incipient stage.—Larger area involved than in incipient, and constitutional symptoms more decided.

Moderately advanced stage.—Well marked changes in percussion and auscultation, with more or less constitutional disturbances.

Advanced stage.—Well marked areas of consolidation, with cavity formation and constitutional disturbances.

Very advanced stage.—Marked increase of all the foregoing signs.

In his fifth annual report of the same institution, he, however, dropped the *very advanced stage*.

Trudeau (32) divides phthisis into three stages only, without exactly defining the areal extent.

Incipient stage.—With but slight local and constitutional involvement.

Advanced stage.—Local disease more extensive, or in an advanced stage, or the local disease may be comparatively slight, with grave constitutional impairment or some complication.

The far advanced stage.—Both physical and rational signs warranting the term.

H. P. Loomis (33), also Stubbert (34), in the reports of the Loomis Sanitarium, classify similarly, distinguishing between incipient, moderately advanced, and advanced stages, and Ashton (35) and Elliott (36) follow this classification in their reports.

If one examines these various classifications, to which many more or less decided modifications by other authors could be added, one can see good points in all of them, be they based upon the clinical manifestations solely, upon a basis which is purely anatomical, or one that is a combination of both.

When one, however, has a larger series of cases to dispose of and intends to classify in a manner in which the anatomical lesions (as shown by physical signs) are attached to certain clinical phases of the disease, then there are cases left over which cannot be disposed of at all, while some of those which have been disposed of under

one or the other combination groups, are found to differ greatly in *prognosis*, which after all is the real object of all classifications, so far as we use them for statistical and comparative purposes. A careful study of the classification of stages recommended by the committee of this association does not appear to me to have sufficiently remedied this serious defect, and I am well convinced that no classification can do this even approximately, so long as it attempts to combine the physical phenomena, especially in regard to extent of area, with the clinical aspect of cases, simply because they stand in no necessary relation, either in the prospect for duration of life, or in the prospect of a clinical cure.

Under such circumstances, one is tempted to resort to the old method of division into clinical stages only, the more so as the attainment of uniformity on a physical sign basis implies, as Turban himself admits, equal training and experience in examination of the chest.

In the classification of my own work, comprising reports of over 3,000 cases, I have therefore paid secondary attention to the physical signs, and have divided my cases into three classes, entirely upon a clinical aspect from my own standpoint of prognosis.

By this method a case is classified regardless of the fact that one or two lobes are the seat of demonstrable alterations, while cases with acute or actively progressive changes, caseous pneumonias, or such with more serious complications and of but limited or less acute local lung disease, go where, from a prognostic standpoint, they really belong. A case recently examined by me, in which the greater part of an upper lobe was the seat of caseous pneumonia with coexisting parenchymatous nephritis and tuberculous ulceration of the larynx, was naturally placed in the most unfavorable class, whereas according to Turban the classification should have been in the first, and according to our committee's recommendation, in the second stage.

While I have found room for improvement in my own classification, especially for making my reports with a view of their ready comparison with those of others, I have made no change in the past, because every one seemed to classify differently, and I proposed to continue consistently at least in my own work, until the profession should adopt a standard that all will follow.

That this standard should reflect the *prognosis* of the cases grouped together as far as possible, I presume all are agreed, and the changes made from Turban's division by our committee can have no other object.

Being deeply interested in the subject ever since I became acquainted with the recommendation of our committee for a uniform classification, I have spent much thought upon the subject, and have endeavored to formulate a substitute that should be an improvement, while making the element of prognosis its chief feature.

In the formulation of such a classification, I have been aided by that of Carl Spengler, of Davos (37), which he has used for many years and which appears in the volume dedicated to Professor Koch on the occasion of his sixtieth birthday.

Dr. Spengler divides his cases in two large groups, the first being non-febrile and therefore inactive; the second group comprises the febrile or active forms of the disease. He then makes three stages under each group.

The first stage includes only those that are what has been termed "closed" cases, that is to say, those in which the process is purely tuberculous, softening and excavation having not yet occurred.

The second stage is that of early or beginning phthisis.

The third stage is that of cavernous phthisis: each stage has an inactive and active group.

For prognostic purposes I believe, however, a division into four stages to be desirable, inasmuch as some cases that would come in the second stage, according to Spengler, ought to be taken out and placed with the third stage, and likewise certain cases that he places in his third stage, would with advantage be classed by themselves, since in these the prognosis for lasting improvement or cure is unfavorable.

It may also be deserving of your consideration to emphasize the distinction between *pure tuberculosis* and *phthisis* more decidedly by not enumerating such cases with those of phthisis, and by classing them as chronic tuberculosis while reserving three stages for phthisis proper.

I have made this a feature of the classification which I submit and believe a careful examination will justify such a course, since an additional aetiological factor, largely dominating the future course of the disease, comes into consideration with the advent of phthisis.

Some may object to the division of each stage into an active and inactive form, thereby really distinguishing between eight classes instead of three or four, as has been the common custom. I believe, however, that for purposes of prognosis this division is unavoidable, and also that when one familiarizes himself with the divisions it will not be found a hardship to observe it.

Dr. Spengler's condition of absolute freedom

DR. VON RUCK'S CLASSIFICATION OF STAGES FOR CASES OF PULMONARY TUBERCULOSIS AND PHTHISIS.

CHRONIC PULMONARY TUBERCULOSIS.

a. Inactive, closed tuberculosis, latent form, free from fever, reacting to tuberculin, with varied extent of physical signs.

b. Active, closed tuberculosis, with mild tuberculous fever (100.5 degrees F. maximum); otherwise same as a.

PULMONARY PHTHISIS.

Class I. Non-febrile Cases.

Class II. Febrile Cases.

First Stage.

a. Inactive, initial phthisis, without demonstrable cavity formation, with bacillary sputum; total quantity not exceeding $\frac{1}{2}$ ounce in 24 hours; passive secondary infection; with or without mild complications on the part of pleura. Temperature normal to 99 degrees F.

b. Active initial phthisis, with moderate tuberculous fever, or a combination of the tuberculous with that of subacute secondary infection. Expectoration not exceeding $\frac{1}{2}$ ounce in 24 hours, with or without mild complications on part of pleura. Temperature not exceeding 101.5 degrees F.

Second Stage.

a. Inactive phthisis, with single, small demonstrable cavity formation. Expectoration not exceeding 1 ounce in 24 hours. Passive secondary infection; with or without mild complications on part of the larynx or pleura or both. Temperature normal to 99.2 degrees F.

b. Active phthisis, with tuberculous fever, or combined secondary fever; demonstrable cavity formation. Expectoration not exceeding 1 ounce in 24 hours. Mild complications on part of pleura or larynx or both. Temperature not exceeding 102.5 degrees F.

Third Stage.

a. Inactive, advanced, cavernous phthisis, with large or multiple cavity formation. Expectoration exceeding 1 ounce in 24 hours. Passive secondary infection; serious complications, tuberculous or otherwise, on the part of larynx, pleura, intestine, or other organs. Temperature subnormal to 99.5 degrees F.

b. Active, advanced, cavernous phthisis, with tuberculous or secondary fever of any degree. Large single or multiple cavity formation. Expectoration exceeding 1 ounce in 24 hours. Complications same as under a, or caseous pneumonia, diffused mixed infection, acute miliary disseminations.

CLASSIFICATION OF RESULTS OF TREATMENT OF PULMONARY TUBERCULOSIS AND PHTHISIS.

<i>Cured.</i>	Patients free from all subjective symptoms, without elevation of temperature, without cough or expectoration. Physical signs absent, or indicative of connective tissue changes or cicatrization. General health restored. Tuberculin test applied three months or later after discontinuance of treatment must have proved negative, or above conditions must have been maintained at least for two years after discharge.
<i>Apparently cured.</i>	Same condition as above, maintained at least for three months after discontinuance of treatment.
<i>Disease arrested.</i>	Decided retrogressive changes in the physical signs, coexisting with corresponding amelioration of symptoms, only slight cough remaining, expectoration not exceeding 2 drachms in 24 hours, still containing tubercle bacilli. General health to be approaching normal state. Temperature must be practically normal, not exceeding 99 degrees F. Such condition must have been maintained for three months or longer.
<i>Greatly improved.</i>	Symptoms and physical signs present on admission must show material reduction, especially cough, expectoration, and fever. Weight and strength, if previously deficient, must show decided increase.
<i>Improved.</i>	Symptoms, such as cough, expectoration, and fever, have grown less. No loss in weight, or gaining on discharge.
<i>Stationary.</i>	No material change in patient's condition. No loss in weight.
<i>Progressive.</i>	Symptoms and physical signs are increased.

from fever for inactive stages of phthisis, I could not think practical, for there are few cases which, while they have a considerable amount of secretions from ulcerated surfaces or cavities, do not show a slight rise at some time during the day, although there is no apparent active or progressive tendency.

A further objection may be urged for the necessity of distinguishing between the sizes of

cavities in classifying between the second and third stages. It is true that this may become a difficult matter in some instances, but I believe that the sputum quantity will aid considerably in this respect, since it represents with a great degree of uniformity the area of ulcerating surfaces from which it is derived.

Large cavities are, however, easily found, and their prognostic feature lies chiefly in the fact that

they rarely can be caused to close without resort to surgical measures, at least not in adults; such cases, therefore, cannot attain a clinical cure.

You will observe the following to be the chief distinctive features for the classification:

For chronic tuberculosis.—The absence of softening, ulceration or excavation.

For initial phthisis.—The destructive area is small, giving as yet no physical signs of cavity, and having a correspondingly limited amount of expectoration.

For phthisis.—The destructive process has extended to such a degree that a small sized cavity is recognizable; the increase of the ulcerating surface corresponding with an increase of sputum. In this stage the larynx may also show a mild degree of involvement.

For advanced cavernous phthisis.—The presence of a large cavity or of multiple cavity formation, again reflected by a correspondingly increased amount of sputum; and with this stage are classed all cases which, regardless of the extent of local destructive changes, have coexisting grave complications, be they tuberculous or otherwise.

We thus dispose of the occurrence of amyloid degeneration, of grave diabetes, of nephritis, and of certain rarer complications on the part of the heart, that may be a feature in any stage of the disease, and likewise of cases of acute caseous pneumonia, diffused mixed infection, acute miliary dissemination, etc.

The distinction of actively progressing from inactive, non-febrile cases is also of obvious advantage.

While this classification is chiefly upon a clinical basis, it reflects the gravity of the cases grouped together, and has the great additional advantage that it requires no extraordinary skill and experience in placing a given case in its proper group.

Another word I would like to add in regard to the classification of the results of treatment.

If we look at the customary classification of results, especially in American reports, we find a fair degree of uniformity, although all classifications in use could be improved by the adoption of more reliable criteria.

Dr. Bowditch is reluctant to make a class of apparently cured cases, and until his last report of the Massachusetts State Sanitarium, he has substituted the word *arrested*, as an equivalent. In the last report, made jointly with Dr. Clapp, the *arrested* and apparently cured cases are classed together, in the same sense and under the same conditions as to the results obtained. In

addition he makes only one more class, representing every shade of improvement.

Trudeau's class of "apparently cured," corresponds to Dr. Bowditch's and Dr. Clapp's cases, but like all others, Dr. Trudeau makes a *special class* for *arrested* cases, in which cough and expectoration with tubercle bacilli are still present, but constitutional disturbances have been absent for several months, and the physical signs show retrograde or arrested progress. Besides he has an *improved class*.

In the Loomis Sanitarium, as also in the Muskoka Cottage Sanitarium, Trudeau's classification prevails and in my reports from the Winyah Sanitarium I have followed it, while I have made two classes for improved cases, according to the degree of benefit attained.

I believe, however, that if we adopt a uniform standard for the classification of results, we can define more accurately the requirements for each group. In cases actually alleged to be cured, there should be no symptoms of any kind, and the result of physical examination should be negative, or give no other evidence than that of connective tissue or cicatricial changes. But instead of a time limit of two years, a negative tuberculin test after three months from the date of discharge should be accepted. In fact, my own opinion is, that this should be an invariable condition. In addition, the state of the patient's general health should be consistent with recovery.

For an *apparent* recovery the conditions must necessarily be the same, or else the recovery cannot be said to be apparent. It becomes unconditional only after a tuberculin test, or expiration of the time stipulated for a cure.

I find very little difference between the *arrested* and the *quiescent* classes in the classification submitted by the committee. In the quiescent class constitutional symptoms *may* be, and in the *arrested* class they *must* be absent. In the former cough with bacillary expectoration is mentioned, and in the latter expectoration containing tubercle bacilli may still be a symptom; and since cough implies expectoration, and expectoration is usually attended with cough, both classes may still cough and expectorate tuberculous sputum in unlimited amount. The same uncertainty prevails in regard to the physical signs; in the quiescent class they may be improved or unchanged, while in the *arrested* class they may or may not persist. The real difference is, therefore, that in the *arrested* class there is a provision of time during which the condition has been maintained.

If you will examine the conditions I have made for *arrested* cases, I believe you will agree with

me as to the desirability of limiting the temperature to practically normal, and stipulating likewise that the cough and expectoration shall be slight, as stated, while the physical signs must show retrogressive changes.

To prevent confusion, I have left out the quiescent class entirely, and substituted a stationary class in its stead, that is to say, one in which there has been no apparent improvement as a result of treatment, while the patient has held his own.

Between this stationary class and the arrested one, I found it necessary to make some provision for improved cases which, when treatment was discontinued, have not received enough benefit to meet all the conditions that justify their inclusion among arrested cases.

The difference between a cured and an apparently cured case, is that the former has proved a cure by a tuberculin test, or by the expiration of two years of good health, without return of symptoms.

Between the cured and arrested cases, the chief difference is that there may be in the latter a still open surface, discharging a limited amount of secretion, which is inconsistent with the acceptance of a cure.

Between these and the improved cases, the classification represents the degree of benefit derived from treatment and, while in arrested cases this degree is more sharply defined, the improved state is evidenced by changes for the better which are a matter of comparison between admission and discharge.

With these remarks I submit to you the classification suggested for your further consideration.

The Medical Association of the Greater City of New York.—A stated meeting of this association will be held in Hosack Hall, New York Academy of Medicine, on Monday, March 13, 1905, at 8.30 p. m. Order of exercises: The Constitutional Treatment of Bright's Disease, by Dr. William H. Porter; discussion to be opened by Dr. Reynold Webb Wilcox; The Treatment of Bright's Disease by Lavage of the Renal Pelves, by Dr. Winfield Ayres; The Treatment of Pyelitis, by Dr. Howard A. Kelly, of Baltimore, professor of gynecology in Johns Hopkins University; discussion by Dr. F. M. Johnson, of Boston, Dr. George M. Edebohl, Dr. Willy Meyer, Dr. Ramon Guiteras, Dr. Frederic Bierhoff, Dr. James Pedersen, and Dr. W. J. Pulley.

Our Subscribers' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at regular intervals. So far as they have been decided upon, the further questions are as follows:

XXXVI.—What diet do you prescribe in typhoid fever? (Answers due not later than March 15, 1905.)

XXXVII.—How do you manage the alcohol habit? (Answers due not later than April 15, 1905.)

XXXVIII.—How would you prevent disease of the vermiform appendix? (Answers due not later than May 15, 1905.)

Whoever among our subscribers (with the limitations mentioned below) answers one of these questions in the manner most satisfactory to the editor and his advisers will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

Only subscribers to the *NEW YORK MEDICAL JOURNAL* AND *PHILADELPHIA MEDICAL JOURNAL* (including regular and volunteer officers of the Medical Corps of the United States Army, Navy, and Marine Hospital Service, commissioned or under contract) will be entitled to compete, and all persons known to be engaged in medical journalism are disqualified. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish.

The prize of \$25 for the best essay submitted in answer to question XXXV has been awarded to Acting Assistant Surgeon G. R. Plummer, of the navy, whose article appears below.

PRIZE QUESTION NO. XXXV.

THE TREATMENT OF BUNIONS.

By G. R. PLUMMER, M. D.,

ACTING ASSISTANT SURGEON, UNITED STATES NAVY.

I order what are known as right and left socks or stockings, which have a straight inner edge to the foot and are normally curved around the toes so as to prevent dragging on the great toe. It would be better to use a sock or stocking which has a separate apartment for the great toe, but it cannot be found on the market, whereas the "right and lefts" are on sale in New York.

The inner edge of the sole of the shoe is made perfectly straight, and although the sole is as wide as the foot, the curve of the toe resembles so closely the curve of the normal toes that it is not clumsy in fact or appearance. It has been my experience that it is better to have the toe box.

The bunion should be bathed night and morning with a four per cent. solution of carbolic acid for a few minutes, and this should be followed by a bath of plain water. The carbolic solution is not only antiseptic, but a decided analgetic.

If, after several weeks' trial of proper foot gear, the bursa is still distended with fluid and it is

necessary to aspirate it, the operation is simple, practically painless, and if antiseptic precautions are practised, a safe one. All the foregoing applies to simple bunion caused by an ill fitting shoe.

Now, there is a class of cases which have been practically ignored in literature, and the management of them requires no little knowledge of the anatomy of the foot, the gouty and rheumatic diatheses, and physical peculiarities. Many cases of bunion are due to flat foot, which causes the great toe to turn out and brings the prominent metatarsophalangeal joint against the side of the shoe. In this case, unless the arch of the foot is restored by a plate, the treatment for simple bunion would fail. In the case of enlarged joints from gouty or rheumatic inflammation, these constitutional diseases would have to be overcome by internal treatment and hygienic living, otherwise the local treatment would not succeed. Four of the five tendons attached to the great toe tend to drag the toe outward, and the question of their abnormal contraction must be taken into account. Whenever possible, no operation should be performed on the metatarsophalangeal joint without an x ray picture being taken as a guide, and in that the sesamoids must not be mistaken for exostoses. As the deformity is often the result of a simple dislocation, the tripod of the foot should be respected and restoration secured by removing wedges from the metatarsal or phalanx, or both, and tenotomy.

KEY WEST, FLA.

Correspondence.

LETTER FROM MONTREAL.

Harmony between the English and French Physicians of Montreal.—*The Governor's Fellowship in Pathology at McGill University.*—*The Royal Victoria Hospital.*—*The McGill Medical Faculty.*—*Marmorek's Serum.*—*Leprosy in Canada.*

MONTREAL, February 18, 1905.

There are signs that the profession of Montreal will soon be a united one and that no longer will there be two camps composed of English and French adherents, respectively. The medical profession of Montreal sat down together at a banquet in the Windsor Hotel on the evening of the 21st of February, the occasion being a joint gathering with the Montreal Medico-Chirurgical Society and La Société médicale as hosts. Too long has the profession in Montreal been divided to the detriment of others than themselves, and

while it was not due to religious feeling, but rather to jealousies of years gone by with which the present generation can have but little to do, it is fitting to thus celebrate the burying of the hatchet.

Dr. Oscar Klotz has resigned the Governor's fellowship in pathology at McGill University, which was first instituted in 1899. The fellowship is tenable for two years by graduates of medicine who have performed some previous research work, and is worth \$500 per annum. Dr. Klotz has done some good work, the most important being on the part played by soaps in the process of pathological calcification, which will shortly be published. Dr. George A. Charlton, who formerly held this fellowship and was subsequently a Rockefeller fellow, has been appointed by the government of the Northwest Territories to establish a bacteriological and pathological station at Regina.

The eleventh annual meeting of the governors of the Royal Victoria Hospital was held in the latter part of January, when the following appointments were made to the staff: Associates in medicine, Dr. Fry, Dr. Cushing, and Dr. McCrae; clinical assistants in medicine, Dr. Burnett and Dr. McAuley; clinical assistants in neurology, Dr. Robertson, Dr. Robins, and Dr. Russell; clinical assistant in ophthalmology, Dr. Tooke; clinical assistant in gynecology, Dr. Goodall; clinical assistant in laryngology, Dr. Hamilton White; registrar and assistant registrar, Dr. Cushing and Dr. McAuley. The report shows that the number of patients admitted during 1904 was 3,054, an increase of 123 over the previous year. The total days of hospital treatment aggregated 74,777, an increase of 666. On the 1st of January, 1904, there were 210 patients in the institution, and during the year 3,096 were discharged, of whom 1,537 were well, 856 were improved, 189 were not improved, 329 were not treated, and 175 died. The number remaining in the hospital at the end of December, 1904, was 184. Of the 175 deaths, 52 took place within forty-eight hours of the patients' admission. This gives a death rate for the year of 3.97 per cent. In the out-patient department 3,992 patients were treated. The income for 1904 amounted to \$148,836. The total daily cost for each patient was \$1.61. Dr. W. J. Cram was appointed externe in the X Ray Department, and Dr. Klotz house pathologist.

The Medical Faculty of McGill University will seek full union with the university. Toward this end the Medical Faculty recently appointed a special committee from their number to wait on the corporation of the university, which they did

at their last regular meeting. This committee was composed of Dean Roddick and Professor Gardner, Professor Ruttan, Professor Adami, Professor Shepherd, and Professor Armstrong. The corporation of the university warmly welcomed the fact that the Medical Faculty desired full union in the institution, and will arrange for a special meeting in the immediate future to confer with regard to details. Dr. Adami has been appointed a Governor's fellow on the corporation.

An important report regarding the Marmorek serum has been prepared by Dr. de Martigny, of Montreal, and presented to the Hygienic Committee of that city. Last June the Hygiene Committee despatched Dr. de Martigny to Paris to make observations and conduct experiments on Marmorek's serum, and this report sets forth his results and gives as well his opinions with regard to the same. He is convinced that Marmorek's serum has a wonderful efficacy and feels positive that, if it were applied at once to the treatment of all consumptives in Montreal, tuberculosis would in ten years be as rare as smallpox now is in that city. Dr. de Martigny concludes his report by strongly recommending Marmorek's serum in the treatment of tuberculosis.

That leprosy is on the decrease in Canada at all events is shown by the report of the superintendent, Dr. Smith, of the Leper Hospital, at Tracadie, N. B., which that official laid before the Federal Parliament a short time ago. The register of the institution shows that there are now fifteen inmates of the lazaretto, ten of whom are males and five females. There were four deaths during the past twelve months. Of the present inmates, nine are French, three Icelandic, and three English. Dr. Smith states that during the year Chaulmoogra oil has been freely used by the inmates with beneficial effects. A short time before he handed in his report Dr. Smith took a tour of inspection through the adjoining parishes and found one undoubted case of leprosy. He also found three persons showing premonitory symptoms. Notwithstanding this, he considers that the disease is rapidly decreasing.

Physicians' Club of Buffalo.—The Physicians' Club held their monthly meeting Thursday evening at the residence of Dr. J. J. Finerty, of 429 Franklin Street. The members and invited guests numbering about 60, were entertained by the host, and the annual election of officers was held. The following physicians were unanimously elected: President, Dr. Joseph S. Porter; vice-president, Dr. D. J. Constantine; secretary treasurer, Dr. William Ring.

NEW YORK, SATURDAY, MARCH 11, 1905.

DISPENSARIES IN THE STATE OF NEW YORK.

We are indebted to the secretary of the State Board of Charities for a statement of the leading points in the forthcoming annual report of the board's Committee on Dispensaries. It appears that during the year ending September 30, 1904, there were open for the whole or a portion of the time 123 dispensaries. A few of them, only twenty, were direct recipients of public funds, but in all they received only the comparatively small sum of \$11,032.40. Sixty-one were operated in connection with institutions receiving public appropriations. It is creditable to private munificence to find that as many as forty-two were maintained entirely without grants of public money.

The State licensing and supervision of these institutions have now been in operation for a little more than five years, and it is stated that in no other part of the country is dispensary work so extensive or under such systematic State regulation as in New York. The State Board of Charities has made rules to govern the conduct of the licensed dispensaries, and its inspector has during the year made a special investigation as to the extent of compliance with these rules. According to a tabulation of his reported findings, the inspection has covered a multitude of points,

most of them of little interest from any other point of view than that of administration. It is to be noted with regret that in only twenty-eight of the dispensaries is clinical or any other instruction given. It is gratifying to learn, however, that in all but one of the twenty-eight clinical instruction is given only with the patient's consent. As regards only one of the board's requirements does there seem to have been decided laxity—that relating to investigation as to applicants' ability to pay for medical treatment and to the recording of the results of such inquiry. Sentimental considerations doubtless lie at the root of the comparative disregard of this requirement. A simple denial of the benefits of the dispensary to such applicants as are obviously not needy, "after questioning, but without further formality," appears to be a less repugnant course, for it is followed in eighty-seven of the dispensaries. The State supervision does not seem to be too searching, and we do not doubt that it is of great utility.

THE ITCH.

Scabies is a disease that few of us see in this country, save in the clinics, but Dr. James Nevins Hyde, of Chicago, one of our leading dermatologists, points out in the March number of the *American Journal of the Medical Sciences* that of late there have been at work two circumstances calculated to lead before long to an unusual prevalence of the itch—namely, an enormous immigration and a great massing of people from all parts of the country at the St. Louis fair. He does not predict that the extension of the pest will be general or formidable, but he thinks that the number of its victims, as observed in both public and private practice, will gradually increase beyond what has heretofore been recorded, and that after that there will be a diminishing prevalence ending in a return to the figures of average years.

Such an unusual visitation, he continues, will occur again when the causes mentioned are repeated, but as yet he looks upon it as doubtful if the opening of the Panama Canal will give rise to a fresh increase in the prevalence of the disease. The facts, he says, and the probabilities

dependent on them occasion one of the serious problems of public hygiene and call for a national education regarding the means of preventing imported filth diseases. The itch is a grievous and loathsome disease, but, fortunately, it is one of those that are the most readily prevented and cured, and it is hardly to be doubted that Dr. Hyde's note of warning will serve as an incentive to measures efficient in preventing to a great extent such a widespread visitation as might otherwise be apprehended. He intimates that the government inspection of immigrants is lax in the matter of scabies, but any such shortcoming can easily be remedied.

MANUEL GARCIA.

On Friday of next week there will be celebrated in London the one hundredth birthday of Manuel Garcia, whose appliances for the visual study of the action of the vocal cords in singing, improvised or adapted many years ago, led to the development of the laryngoscope of the present day. In spite of his advanced age, Garcia is said to be in fairly good physical condition and in the enjoyment of mental faculties practically unimpaired. Though his long life has been devoted to music, his discovery is everywhere recognized as having called modern laryngology into being, and the celebration, as is fitting, will be the joint work of the medical profession and of the musicians. It is to be held in the rooms of the Royal Medico-Chirurgical Society.

Seldom does it happen to a man to be thus honored by the members of two professions, and rarely, too, does a man of prominence reach the age of a hundred years. The occasion therefore will be exceptionally memorable, Garcia was fifty years old when his paper entitled *Physiological Observations on the Human Voice* was presented before the Royal Society, and that organization and the laryngological societies of various countries, including our own, will take part in the ceremonies of March 17th.

Although it is generally understood that Garcia was disappointed with the results of his laryngoscopic studies from the point of view of a teacher of singing, he has for many years had the satisfaction of knowing that they led to the

establishment on a sound basis of a special branch of medical practice that has shown brilliant progress. The formal acknowledgment of this result of his labors is a tribute that is undeniably his due. His memory will always be cherished in the annals of medicine.

A SPECIAL PERIL TO SURGEONS.

There was recently tried in the District Court of Ramsey County, Minnesota, a case which calls attention to a peril which threatens every surgeon, and which seems to me so important that I believe it should be brought prominently to the attention of the whole medical profession. The circumstances of the case are as follows: A patient, a woman, was referred by her family physician to a surgeon for trouble with her ears. Examination by the surgeon of the ear concerning which she made her chief complaint disclosed a condition which seemed to him to call for a surgical operation, to which the patient consented. At the time of the operation, the patient having been anæsthetized, a more careful examination was made of both ears than had been possible without anæsthesia. This examination showed that both ears were diseased, but that the condition of the left ear was worse than that of the right, and in the surgeon's opinion immediate removal of the ossicles was demanded in the left ear in order to prevent an extension of the disease that might threaten the patient's life. The family physician and some other physicians were present, and all agreed to the diagnosis and as to the necessity of an operation; the operation was then performed. When the patient recovered from the anæsthesia, the circumstances were explained to her and she was apparently satisfied with what had been done and agreed to have the other ear operated upon at a later date.

A few days afterward, the patient having in the mean time talked the matter over with friends and (presumably) lawyers, declined further treatment from the surgeon, and later filed a suit against him, charging him with malpractice, accusing him of having by mistake operated on the wrong ear and demanding heavy damages. When the case came up for trial, and it was demonstrated by competent witnesses that the surgeon

had made no mistake, but had deliberately operated on the left ear, on account of the serious and dangerous condition present. the plaintiff's attorneys asked and were given leave to amend their complaint, withdrawing all charges of malpractice, and a new trial was granted, whereat the surgeon was charged with technical assault, the assault consisting in operating on a portion of the body which he had not been employed to operate on. The case was tried and the plaintiff was awarded the enormous damages of \$14,225.50. The judge was apparently satisfied that the plaintiff had a cause of action for assault, since he refused to direct a verdict, although later he granted a motion for a new trial of the case on the ground that the damages were excessive.

Circumstances analogous to those in the foregoing case are of daily occurrence among surgeons, and if this case is finally decided in favor of the plaintiff, I predict an epidemic of similar suits all over the country. Let us suppose that a surgeon makes a diagnosis of appendicitis and on opening the belly finds a suppurating tube; if he removes this tube is he guilty of assault? Suppose that he makes a diagnosis of disease of the right ovary or tube and finds at the operation disease of the left ovary or tube, must he sew up the belly and wait for authority from the patient before doing what should be done at once? Such would seem to be the law.

Of course no surgeon has the right to operate upon any patient without the permission of that patient or of some one in authority to give that permission, but when a patient has placed himself or herself in the hands of a surgeon for an operation, has the surgeon no discretion as to the detail of that operation? Must he outline every step of his procedure in advance, and does he render himself liable for assault in case he should find it necessary to do, and does, something which he had not beforehand explained to the patient? I do not mean to assert that a surgeon would be justified in operating upon a portion of the body remote from that concerning which the patient had consulted him; but it behooves the surgeon to find out whether he is or is not to do what the exigencies of the case seem to him to demand when he undertakes to perform

a surgical operation for the cure of a certain disease or for the relief of certain symptoms concerning which his patient has consulted him, and when an operation has been agreed upon.

Few surgeons go through life without the annoying and expensive experience of having to defend a malpractice suit, and there are in every community lawyers who make their living by hunting up and prosecuting such suits. These suits have become so numerous of late years that insurance companies have appeared offering defense policies which pay the expense of such suits and which in some cases pay the damages up to a certain specified sum. If the case above mentioned is finally decided in favor of the plaintiff, a new field and a lucrative one will be opened for the shysters who fatten upon damage suits and malpractice suits, and the surgeon will do well to surround himself with all possible precautions before undertaking any surgical operation; it would probably be wise for him to provide himself with a blank form which, signed by the patient and properly witnessed, would give him authority to do whatever he believed it necessary and proper to do in each individual case.

BURNSIDE FOSTER.

CALCIUM CHLORIDE AS A HÆMOSTATIC.

Calcium chloride seems to be coming into more varied therapeutical use than was formerly made of it. Boas (*Therapie der Gegenwart*, 1905, No. 7; *Berliner klinische Wochenschrift*, January 23rd) recommends it as a rectal hæmostatic. In cases of bleeding hæmorrhoids half an ounce of a ten per cent. solution is to be injected into the rectum after the morning evacuation, and retained for some time. If the hæmorrhage is severe, an evening injection also will be necessary. He has used it successfully in other rectal hæmorrhages, such as that due to carcinoma. If the salt is chemically pure, it will cause no discomfort; otherwise it may give rise to burning pain and tenesmus.

A BACILLUS OF BALANITIS.

More and more are we coming to recognize, or at least suspect, a parasitic cause for various diseases. Ordinary balanitis is ascribed by H. Vincent (*Annales de dermatologie et de syphiligraphie*, June, 1904; *Berliner klinische Wochenschrift*, February 13th) to a bacillus. It is pathogenic

for animals, does not take the Gram stain, grows on ordinary media, and exhales a foetid odor.

OUR RAILWAY SLAUGHTER.

Evidence is accumulating to show the unworthy preeminence of the United States in manslaughter by railway accidents. A Prussian cabinet minister has recently stated that thirty-six times as many persons are annually killed or wounded in such accidents in this country as in Prussia.

HUMAN AND BOVINE TUBERCULOUS DISEASE.

In a recent contribution to the casuistics of the relations of human and bovine tuberculous disease (*Archiv. für pathologische Anatomie und Physiologie und für klinische Medicin*, clxxvii, 3; *Berliner klinische Wochenschrift*, January 23rd) Ipsen records the case of a child, ten months old, in which there was found post mortem ordinary tuberculous disease of the lungs, the intestines, and other organs, together with an affection of the intestinal peritonæum corresponding to one of the forms of the disease in cattle, in both its gross and its microscopical appearances. Such cases, it is remarked, are very rare in literature.

News Items.

Society Meetings for the Coming Week:

MONDAY, March 13th.—New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); Medical Association of the Greater City of New York; Society of Medical Jurisprudence, New York; German Medical Society of the City of New York; New York Medicohistorical Society (private); New York Ophthalmological Society (private); Gynecological Society of Boston; Burlington, Vt., Medical and Surgical Club; Norwalk, Conn., Medical Society (private); Corning, N. Y., Medical Association.

TUESDAY, March 14th.—New York Academy of Medicine (Section in Genitourinary Surgery); New York Medical Union (private); New York Obstetrical Society (private); Buffalo Academy of Medicine (Section in Medicine); Kings County, N. Y., Medical Association; Rome, N. Y., Medical Society; Medical Society of the County of Rensselaer, N. Y.; Newark, N. J., Medical Association (private); Trenton, N. J., Medical Association; Clinical Society of the Elizabeth, N. J., General Hospital and Dispensary; Northwestern Medical Society of Philadelphia; Practitioners' Club, Richmond, Ky.; Richmond, Va., Academy of Medicine and Surgery.

WEDNESDAY, March 15th.—Woman's Medical Association (New York Academy of Medicine); New York Society of Dermatology and Genitourinary Surgery (private); New York Academy of Medicine (Section in Genitourinary Diseases); Medicolegal Society, New York; Northwestern Medical and Surgical Society of New York (private); New Jersey Academy of Medicine (Newark).

THURSDAY, March 16th.—New York Academy of Medicine; Brooklyn Surgical Society; New Bedford, Mass., Society for Medical Improvement (private); Medical Society of City Hospital Alumni, St. Louis; Atlanta Society of Medicine.

FRIDAY, March 17th.—New York Academy of Medicine (Section in Orthopaedic Surgery); New York East Side Physicians' Association; Manhattan Medical and Surgical Society (private); Clinical Society of the New York Postgraduate Medical School and Hospital; Baltimore Clinical Society; Chicago Gynecological Society.

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending March 4, 1905:

	March 4.		February 25.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	262	6	292	5
Diphtheria and croup	276	30	258	45
Scarlet fever	248	22	261	14
Smallpox	3	..	5	1
Chickenpox	98	..	121	..
Tuberculosis	390	188	318	164
Typhoid fever	42	10	28	10
Cerebrospinal meningitis	60	..	49
	1,309	316	1,283	288

Commissioner Darlington, of the health board, reports that the death rate for last week was lower than the corresponding week in any previous year. During the previous administration the death rate for that specific week was 20.67 per thousand. This remained the record until last week, when it went down to 20.47 per thousand. Commissioner Darlington hopes to get the year's death rate below that made during any former administration. The lowest figures were made in 1903, when the rate went down to 18.18 per thousand. "During that year," said Commissioner Darlington, "we had a warm winter and a cool summer. If we have as favorable weather conditions this year I expect to see the death rate fall below 18."

The Annual Dinner of the Society of Medical Jurisprudence is to be held on Saturday evening of this week at the Hotel Astor, Forty-fourth Street and Broadway.

A Clinic on Cancer.—At the close of the course of special lectures by Dr. L. Duncan Bulkley at the New York Skin and Cancer Hospital, Nineteenth Street and Second Avenue, New York, on Wednesday, March 29th, at 4.15 p. m., there will be a clinic on cancer by Dr. William Seaman Bainbridge, of the hospital staff. A number of interesting cases will be on exhibition.

Aid Society of St. Catherine's Hospital, Brooklyn.—The officers of this society are: President, Mrs. Joseph Eppig; vice-presidents, Mrs. Ann Brown, Mrs. M. Bannon, and Mrs. C. Hillenbrand; recording secretary, Mrs. John J. Hagerty; corresponding secretary, Sister Mary Mercedes, O. S. D.; treasurer, Sister Superior Mary Emilia, O. S. D.; board of directors, Miss Mary Carroll, Miss Ellen Keefe, Mrs. James Cooke, Mrs. J. Leyendecker, Mrs. A. Kramer, Mrs. T. Hess, Mrs. F. Ibert, and Mrs. B. Uzmman.

Roosevelt Hospital.—At a meeting of the trustees of the Roosevelt Hospital, held on February 28th, Dr. James W. McLane, former president of the College of Physicians and Surgeons in New York, was elected president of the hospital. W. Irving Clark was elected vice-president; W. Emelen Roosevelt, secretary; and Richard Trimble, treasurer.

Grateful because of their quick recovery, two private patients in the hospital have given the institution \$5,000 each, for the opening of one of the public medical wards which has been closed for some time, owing to lack of funds. The gifts were not solicited.

Nurses Graduated from the New York Hospital.—Elizabeth Munroe Bowers, Katharine L. Bowers, Elizabeth Burroughs, Dora Browning, Alice C. Ellison, Ella Fligg, Gertrude I. A. Forbes, Isabelle Gordon, Florence Louise Golding, Mary Adeline Harding, Georgiana Elizabeth Hay, Mrs. Ethel Josephine Da Costa Hosking, Martha Josephine McCabe, Margaret Felicia Marie Moir, Margaret Paisley, Isabel Phymister, Elizabeth Y. Richmond, Caroline Straub, Winifrede Salter, Lillian Evelyn Smardon, Henriette Beta Tatlatscheck, Alice Augusta Todd, Helen Van Meter, Mrs. Mary Wharton Van Huzon, Louise Tilden White, and Anna Galena Warren.

Rosary Hill Home and St. Rose's Free Home.—A series of lectures on The Women of the Renaissance is to be given by Dr. J. J. Walsh, Ph. D., LL. D., for the benefit of Rosary Hill Home, Hawthorne, Westchester County, N. Y., and St. Rose's Free Home, Cherry Street, New York. These two branches of the same charity are for the relief of incurable cancer patients and are under the care of Sister M. Alphonse (Mrs. Rose Hawthorne Lathrop, daughter of Nathaniel Hawthorne), and the Servants of Relief. This charity is the only one which undertakes these cases and is of vital importance to these sufferers. Aside from the charity to be helped, the lectures promise to be otherwise interesting.

The New York Academy of Medicine.—The section in medicine will meet on Tuesday, March 21, 1905, at 8.15 p. m. Order: Annual election of officers; presentation of cases; clinical reports: A Case of Acute Polyarticular Gout, by Dr. N. B. Potter; A Sterile Purulent Joint, following Acute Articular Rheumatism, by Dr. H. S. Carter; papers: The Present Clinical and Bacteriological Status of Vincent's Angina, by Dr. W. N. Berkeley; discussion by Dr. Mayer, Dr. Thacher, Dr. Simpson, Dr. Lipman, Dr. Sobel, Dr. Bell, and others; Recent Studies in the Diagnosis of Rabies, by Dr. B. W. Poor; discussion by Dr. Biggs, Dr. Dulles, Dr. Ewing, Dr. Park, Dr. Brooks, Dr. Huddleston, Dr. Wilson, Dr. Bailey, and others. Charles H. Lewis, M. D., chairman; E. E. Smith, M. D., secretary, 26 East Twenty-ninth Street.

A meeting of the section in laryngology will be held March 17th, at 8.15 p. m., in honor of the one hundredth birthday of Signor Manuel Garcia. Order: Manuel Garcia, Teacher, Discoverer, and Man, by Dr. James E. Newcomb; address, by Walter Damrosch, Esq.; The Future of the Laryngoscope and the Study of Laryngology, by Dr. John N. Mackenzie. Lewis A. Coffin, M. D., chairman; Lee Maidment Hurd, M. D., secretary, 15 East Forty-eighth Street.

A Conference on Hospitals.—The New York Association for Improving the Condition of the

Poor is to have a conference on hospital needs and hospital finances, to be held in the assembly hall of the United Charities Building, 109 East Twenty-second Street, at 2.30 p. m., on Thursday, March 23rd. The hospitals, as well as various charitable organizations having daily contact with distress arising from sickness and physical injury, have been invited to send at least three delegates from their boards of directors and ladies' auxiliaries. The association was prompted to this action by repeated announcements made through the press and through hospital reports showing that the hospitals of New York do not receive that ample support which their needs require and their merits deserve. Heavy annual deficits are the rule rather than the exception, social deficits as well as financial, for in many hospitals work is curtailed for lack of means. Although an injury to medical science, and thus to the whole community, such curtailment bears hardest upon the poor.

To Establish a Hospital for Cancer Cases.—A movement is on foot among prominent New York medical men for the establishment of a hospital in which cancer may be treated scientifically, and where inoperable and destitute cases may be cared for. The commissioners of the State Board of Charity at a recent hearing approved the granting of a certificate of incorporation for such an institution, when sufficient money is in hand to run the hospital a year. The name decided on is Fairhaven Sanitarium, and Henry R. Wilson, president of the Lincoln Trust Company, has undertaken to raise \$10,000, which amount will be sufficient to begin operations. The medical board will include:

Dr. William B. Coley, attending surgeon, General Memorial Hospital; Dr. B. F. Curtis, attending surgeon, Bellevue Hospital; Dr. George F. Shrady, consulting surgeon, General Memorial Hospital; Dr. Joseph A. Blake, professor of surgery, P. and S., attending surgeon, Roosevelt Hospital; Dr. Edwin B. Cragin, professor of gynecology, P. and S., attending gynecological surgeon, Roosevelt Hospital; Dr. Austin Flint, Jr., attending gynecologist, Bellevue Hospital; Dr. George H. Ballery, private sanitarium; Dr. Walter B. James, attending physician, Presbyterian and Roosevelt Hospitals; Dr. Alexander Lambert, attending physician, Bellevue Hospital; Dr. Walter F. Chapelle, attending surgeon, Manhattan Eye and Ear Hospital; Dr. Gertrude B. Kelly, attending surgeon, New York Infirmary; Dr. Marie Chase, attending surgeon, New York Infirmary; Dr. Grace Peckham Murray, adjunct professor of gynecology, Postgraduate Hospital; Dr. Anna M. Galbraith, attending neurologist, Orthopaedic Hospital; Dr. Josephine Walter, attending physician, New York Infirmary and Montefiore Hospital.

PHILADELPHIA.

Deaths.—Dr. William B. E. Miller died at Hightstown, N. J., on March 2nd, aged 56 years. Dr. Miller was a prominent veterinarian and for several years had served as the federal inspector of cattle at Jersey City.

Dr. D. W. Dundore died at Womelsdorf, Pa., on February 23rd, aged 48 years. Dr. Dundore graduated from the medical department of the University of Pennsylvania in 1879.

Scientific Society Meetings for the Week Ending March 18, 1905.—Monday, March 13th, Section on General Medicine, College of Physicians;

Wills Hospital Ophthalmic Society. Tuesday, March 14th, Philadelphia Pædiatric Society; Botanical Section, Academy of Natural Sciences. Wednesday, March 15th, Section in Otology and Laryngology, College of Physicians; Association of Clinical Assistants, Wills Hospital. Friday, March 17th, University of Pennsylvania Medical Society; American Philosophical Society.

Charitable Bequests.—On March 1st the directors of the various Jewish charitable organizations held a meeting at the Mercantile Club, which was the result of an invitation issued by the Federation of Jewish Charities. The president of the federation, Jacob Gimbel, announced that within the last few days a subscription of more than \$15,000 had been obtained from 70 of the 1,800 members of the organization. The larger subscriptions were asked for on account of the increased needs of the constituent societies of the federation. By the will of Mary H. Beagh \$500 is bequeathed to any institution that her sister decides to enter.

College of Physicians.—At the meeting of the College of Physicians, held Wednesday evening, March 1st, Dr. Robert N. Willson read a paper entitled *The Relief of Uremic Hemiplegia and Other Uremic States by Lowering Intracranial Pressure*. Dr. T. L. Coley read a paper entitled *The Famous Controversy Concerning the Internal Use of Cantharides—an Historic Sketch*. Dr. Alfred C. Wood read a paper entitled *Gallstone Obstruction of the Bowel; Report of a Case; Removal of the Stone by Operation; Recovery*. Dr. John B. Roberts read a paper entitled *The Gardener's Spade Deformity and the Silver Fork Deformity in Fractures of the Carpal End of the Radius*. The honorary librarian announced the addition of sixty-seven volumes to the library during February.

The Health of the City.—During the week ending February 25, 1905, the following cases of transmissible diseases were reported to the Bureau of Health:

	Cases.	Deaths.
Typhoid fever.....	77	10
Scarlet fever.....	52	0
Chickenpox.....	85	0
Diphtheria.....	69	15
Cerebrospinal meningitis.....	9	1
Measles.....	15	0
Whooping cough.....	24	0
Tuberculosis of the lungs.....	62	51
Pneumonia.....	90	92
Erysipelas.....	15	0
Puerperal fever.....	1	5
Tetanus.....	1	0

The total death rate for the week was 579, in an estimated population of 1,438,318, corresponding to an annual death rate of 20.93 per 1,000 population. The total infant mortality was 94; 76 under one year and 18 between one and two years. There were 29 still births; 19 males and 10 females. The following deaths from other transmissible diseases were reported: Malarial fever, 1; tuberculosis other than tuberculosis of the lungs, 13; dysentery, 1; diarrhoea and enteritis under two years, 11. No unusual meteorological phenomena were recorded by the weather bureau.

Annual Meeting of the Associated Health Authorities and Sanitarians of Pennsylvania.—The

twelfth annual meeting of the Associated Health Authorities and Sanitarians of Pennsylvania was held at Harrisburgh on February 14th and 15th. The meeting endorsed the following bills now before the State legislature: (1) For the establishment of a Bureau for the Registration of Vital Statistics. (2) For the protection of the inland water supplies of the State. (3) For the establishment of a State department of health. The annual address was delivered by Dr. John S. Fulton, secretary of the State board of health of Maryland, who spoke on Vital Statistics. A "symposium" on tuberculosis was offered by the members of the medical staff of the Phipps Institute of Philadelphia. Dr. Charles J. Hatfield spoke on *Methods of Infection*; Dr. William B. Stanton spoke on *the Importance of Popular Education in regard to Tuberculosis*; Dr. Joseph Walsh spoke on *the Necessity of Early Diagnosis*. Among sanitary and prophylactic measures recommended was the free State distribution of antitoxine. Dr. A. H. Stewart, of Philadelphia, read a paper on *Disinfection for Communicable Diseases*. Dr. Harry B. Bashore, of West Fairview, read a paper on *the Neglect of Rural Hygiene*. The following officers were elected:

President ex officio, Governor Pennypacker; first vice-president, Dr. T. M. McKee, of Kittanning; second vice-president, Dr. R. S. Maison, of Chester; third vice-president, Dr. H. D. Heiler, of Hilltown; treasurer, Dr. Jesse Green, of West Chester; secretary, Dr. W. R. Batt, of Philadelphia.

Medical Society Programmes.—The University of Pennsylvania Medical Society met at 1925 Chestnut Street on Friday, February 17th. Dr. M. B. Hartzell read a paper entitled *The So Called Tuberculides, with a Report of Two Cases of the Papulonecrotic Variety*. Dr. William Pepper read a paper on *The Medical Faculty of the University of Pennsylvania from 1765 to 1905*.

The following was the programme of the section in otology and laryngology of the College of Physicians at its meeting held February 15th:

Dr. P. S. Donnellan, *A Case of Leucoplakia Buccalis. Specific Pharyngitis Complicated with Periamygdalear Abscess*; Dr. W. G. B. Harland, *The Cosmetic Use of Paraffin in Changing the Shape of the Nose*.

The following was the programme of the section in ophthalmology of the College of Physicians at its meeting held February 21st:

Dr. Charles A. Oliver, *Description of a Single Stitch Operation for Advancement of the Exterior Ocular Muscles*; Dr. G. E. de Schweinitz, *Traumatic Aniridia*; Dr. G. E. de Schweinitz and Dr. B. F. Baer, Jr. (by invitation), *Four Cases of Sarcoma of the Choroid and One Case of Glioma of the Retina, with Microscopic Examinations*; Dr. C. F. Clark, of Columbus, O. (by invitation), *Astigmatism Following the Operation for the Extraction of Cataract*; Dr. W. Zentmayer, *A Case of Paralysis of the Upward Movement of Both Eyes*; Dr. H. F. Hansell, *Some Further Experiences in the Treatment of Ocular Inflammations by Diaphoresis*; Dr. E. A. Shumway, *Exhibition of a New Ophthalmic Outfit for Bedside Examination*.

The Pathological Society, at its meeting February 23rd, offered the following programme:

Dr. C. Foulkroud (by invitation), *Diverticulum of Fallopian Tube; Tuberculous Ulcer of Tongue; Sarcoma from a Patient Sixty-six Years of Age*; Dr. R. C. Rosenberger, *Homogenized Cultures of Tubercle Bacilli*; Dr. D. H. Bergy, *Influence of Pasteurization on the Chemical and*

Physical Qualities of Milk; Dr. M. E. Pennington, Comparison of Pasteurized and Raw Milk; Dr. J. Evans, Does Milk Possess Germicidal Properties.

The following was the programme of the Philadelphia County Medical Society at its meeting, February 22nd:

Dr. Myer Solis-Cohen, The Pasteur Preventive Treatment of Rabies at the Patient's Home: a Report of Two Cases; Dr. Joseph Price, Surgical Intervention in Cases of General Peritonitis from Typhoid Perforation and from Acute Gonococcus Infection; Dr. H. Emerson Wetherill, Hygrometry: Some Practical Results from the Measurement of the Perspiration in Health and Disease.

The following was the programme of the Philadelphia Neurological Society at its meeting, February 28th:

Dr. Ralph Pemberton, for Dr. W. G. Spiller, A Case of Lumbosacral Syringomyelia; Dr. William G. Spiller, A Case of Progressive Muscular Dystrophy with Atrophy of Bone, and A Case of Tabetic Facial Palsy; Dr. D. J. McCarthy, A Case of Tuberculosis with Graves's Syndrome; Dr. T. H. Weisenburg, A Case of Hemorrhage in the Pons, and A Case of Hemorrhage in the Floor of the Aqueduct of Sylvius; Dr. George E. Price, A Case of Malarial Infection Presenting Symptoms of Multiple Neuritis; Dr. Alfred Gordon, Clinical and Pathological Report of a Case of Lead Poisoning with Remarks on the Pathogenesis of the Disease.

GENERAL

Bayonne Hospital.—Dr. Lucius F. Donohoe has resigned the secretaryship of the medical board of the Bayonne, N. J., Hospital, after ten years' service.

Dr. James H. Whaley, of Rome, N. Y., health officer, has been appointed superintendent of the O. and W. Railroad, as the resident physician for that road in that city.

Richmond Academy of Medicine and Surgery.—The subject announced for discussion at the next meeting of this association, on March 14th, is Conservative Gynecology, and the discussion will be led by Dr. Edward McGuire and Dr. Charles R. Robins.

Dinner in Detroit to an English Surgeon.—Dr. J. B. Kennedy gave a banquet at the Russell House, Detroit, Tuesday evening, in honor of C. A. Rankin Nitch, fellow of the Royal College of Surgeons and chief surgeon of St. Thomas's Hospital, London, England. Dr. Guy L. Kiefer presided as toastmaster.

The Children's Free Hospital, of Milwaukee, has recently received the sum of \$1,000 to support four free beds in that institution for one year, with the promise that the subscriptions will be continued indefinitely. The donors are Mrs. Ferdinand Schlesinger, Mr. Charles Catlin, and the Infants' Ward Association.

Floyd County, Ky., Medical Society.—Officers have been elected by this society as follows: President, Dr. H. S. Wolfe; vice-president, Dr. George H. Cannon; secretary treasurer, Dr. Austin Funk; censors, Dr. E. P. Easley, Dr. J. F. Weathers, and Dr. W. J. Leach; delegate to the State meeting, Dr. C. W. McIntyre.

La Salle Hospital, Chicago.—Reorganization of the La Salle Hospital staff has been effected, and Dr. O. E. Wald is now surgeon in chief of

the institution. The president is Dr. B. S. Henderson, of the Cook County Hospital, and Dr. G. A. Raithel is secretary and treasurer. Dr. Wald has been connected with Augustana Hospital and also with Bethesda Hospital.

Gift to Westminster Hospital, London.—The sum of £1,000 has been presented by Mr. Edward Heron-Allen to the Westminster Hospital, London, Eng., to endow a bed in one of Dr. Murrell's wards "in recognition of his valuable contributions to pharmacology and his researches on the action of remedial agents in the treatment of disease."

Association of American Medical Colleges.—By vote of a two thirds majority of all the colleges voting, it has been decided that the next meeting of this association will be held in Chicago, Monday, April 10, 1905. Detailed information as to place of meeting, and programme, will be published later. Fred C. Zapffe, M. D., secretary.

Lebanon Hospital Training School for Nurses.—This institution graduated the following young women on February 22nd: Miss Sarah A. Edenberg, Miss Nessie Jaffe, Miss Meta Jaeger, Miss Margarete McCullum, Miss Dorces Crozier, Miss Harriette A. Rosenbluth, Miss Margarette Donovan, Miss Madeline Holderer, Miss Lillian Barit, Miss Yetta Sadusky, Miss Theresa Grupe, and Miss Anna Chichester.

The Gross Prize.—Dr. J. H. Wright, director of the pathological laboratory of the Massachusetts General Hospital, has been awarded the \$1,200 Gross prize. This prize is given by the trustees of the Philadelphia Academy of Surgery, once in five years. The subject of Dr. Wright's essay was Biology of the Microorganism of Actinomycosis, founded upon his own pathological investigations at the Massachusetts General Hospital. Dr. Wright is a Johns Hopkins graduate, about 35 years of age, is on the staff of the Massachusetts General Hospital, and is an instructor in the Harvard Medical School.

Nurses Graduated from the Massachusetts General Hospital.—Edith Edna Deland, Nellie Jane Harvey, Helen Genevieve Cody, Aletta Alvildia Clark, Olga Emilie Ahler, Izah Mitchell, Amy Otis Gamage, Violet Laura Kirke, Justina Adeline Briggs, Annie Catharine Carstensen, Catharine Beattie, Olive Blanche Golding, Mary Stella Doherty, Mary Eulalia Smyth, Miriam Bertha Holder, Maude Evelyn Retallick, Nellie Maude Ford, Nellie Addie Stevens, Mary Rose Walsh, Rose Butler, Katherine Roche Moloney, Hannah R. Hogan, Mabel J. Seaver, Gertrude B. Hislop, Lena B. Tompkins, Mary A. MacNeil, Grace P. Hurlbut, Emma A. Armstrong, and Jessie L. Brown.

Pneumonia in Chicago.—There were 162 fewer deaths from pneumonia—nearly 24 per cent. less—than during February, 1904; but the consumption mortality remains substantially unchanged—285 and 278, respectively. Since the beginning of the current pneumonia season, October 1, 1904, up to March 4, 1905, there have been 1,299 deaths

from consumption, and 193 from pneumonia, out of a total of 11,350 from all causes. These figures give proportions of 11.4 per cent. of the total mortality for consumption, 18 per cent. for pneumonia, and an excess of 49 per cent. of pneumonia over consumption. There were only 3 deaths reported from typhoid fever during the week and only 15 for the month of February.

A Medical Library for Atlantic City.—A medical library has been established by the Atlantic City Academy of Medicine, and this society has entered into an arrangement with the Atlantic City Free Public Library by which a room has been set apart for its books and periodicals. These will, however, only be given out to members of the academy and their friends, as it is deemed unwise to allow the public free access to medical books. Physicians visiting Atlantic City will be extended every courtesy the library can offer. Contributions on medical subjects will be gladly received and may be directed to Dr. William Edgar Darnall, president of the academy, or Dr. Philip Marvel, chairman of the committee.

Statement of Mortality in Chicago for the Week Ending March 4, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's estimated mid-year populations of 1,990,750 for 1905, and of 1,932,315 for 1904:

	Mar. 4, 1905.	Feb. 25, 1905.	Mar. 5, 1904.
Total deaths, all causes.....	627	637	625

Obituary Notes.—Dr. Alvah R. Cummings, one of the oldest physicians in New Hampshire, died February 26th, in Claremont, N. H., aged 80 years. He graduated from the medical department of Dartmouth College in 1852, and most of his professional life was spent in Claremont. He was president of the Cottage Hospital, and was the oldest member of the New Hampshire Medical Society.

Dr. Adolph Zierlin, an honorary member of the faculty of the University of Tübingen, Germany, from which he graduated over fifty years ago, died in Cincinnati, February 28th, aged 90 years. He served during the Civil War as a surgeon.

Dr. George R. Metcalf, of St. Paul, Minn., died in Orrieto, Italy, suddenly on March 1st. He was 57 years old, a native of Brattleboro, Vt., a

graduate of Amherst College and the College of Physicians and Surgeons of New York, and practised for some time in New York.

Dr. Walter S. Christopher, a well known paediatrist, died in Chicago on March 3rd, aged 46 years. He inaugurated medical inspection in the public schools while a member of the school board. Dr. Christopher was a member of many medical societies, and a liberal contributor to the medical press.

Dr. John J. Prendergast, a prominent Brooklyn physician, died March 1st, aged 58 years. He graduated from Seton College in 1864, and from the New York College of Physicians and Surgeons in 1868. He also took a course at Columbia law school. In 1888, together with Dr. Thomas R. Porley, Dr. Prendergast founded the Manhattan Eye and Ear Hospital. He was for several years connected with St. Francis's Hospital, Jersey City.

Health in Michigan During February, 1905.—Reports to the State Board of Health, by representative physicians in active general practice, in different parts of the State, show the diseases which caused the most sickness in Michigan during the month of February (four weeks ending February 25th), 1905, as follows:

Diseases arranged in order of greatest prevalence in this month.	Number of reports received for this month.....		Per cent. of reports stating presence of disease.

At the State Capitol for the month of February, 1905, compared with the average for the corresponding month in the ten years, 1895-1904, bi-daily observations for the State Board of Health show the prevailing direction of the wind to have been west, instead of northwest, the velocity .8 of a mile per hour greater, the average temperature 3.69 degrees lower, the average daily range of temperature 1.3 degree less, the average daily range of atmosphere pressure .004 of an inch greater, the precipitation .55 of an inch less, the absolute humidity the same, the relative humidity more, the day and night ozone much less, and the depth of water in the observation well 8 inches less. For the month of February, 1905, compared with the average for February in the ten years, 1895-1904, smallpox and

cholera morbus were more than usually prevalent; and pneumonia, inflammation of kidney, erysipelas, scarlet fever, inflammation of bowels, intermittent fever, measles, diphtheria, remittent fever, whooping cough, and dysentery were less than usually prevalent.

THE MOST DANGEROUS COMMUNICABLE DISEASES.

Including reports by regular observers and others, meningitis was reported present in Michigan during the month of February, 1905, at 7 places; whooping cough, at 16 places; diphtheria, at 64 places; measles, at 68 places; typhoid fever, at 93 places; scarlet fever, at 105 places; smallpox, at 106 places; pneumonia, at 142 places; and consumption, at 251 places. Reports from all sources show meningitis reported present at 8 places less; whooping cough, at 6 places more; diphtheria, at 19 places less; measles, at 5 places more; typhoid fever, at 15 places less; scarlet fever, at 4 places less; smallpox, at 2 places more; pneumonia, at 41 places more; and consumption, at 16 places less, in the month of February, 1905, than in the preceding month. Henry B. Baker, secretary.

Statement of Mortality in Chicago for the Twelve Months Ending December 31, 1904, compared with the corresponding period of 1903. All death rates computed on United States Census Bureau's estimated midyear populations of 1,943,315 for 1904 and of 1,873,880 for 1903:

	1904.	1903.	Dec. 1904.

If the prospect for the immediate future is discouraging a retrospect of the year as a whole is full of encouragement. A total of 2,614 fewer deaths among a population some 60,000 more than last year; a reduction of 1,224 deaths of children under five years of age, including 927 of children at the milk feeding period of life; the best sanitary quality of the public water supply ever furnished, and, as a consequence of the latter, a vanishing death rate from typhoid fever: a successful battle with frequent importations of smallpox—are among the features of the year upon which the commissioner of health bases the claim that Chicago has maintained its record for high-

est degree of healthfulness among all the principal cities of the world—those having populations of more than 300,000 each. Chicago's water supply is at last among the best on earth—thanks largely to the substantial completion of the South Side Intercepting Sewer System by the city. Since the latter part of September the water from all tunnels has been found, by the rigid tests of the department laboratory, to be as good as the samples taken twelve miles from shore, which is the department standard of purity or "safety." The result is seen in the lowest typhoid fever death rate in the history of Chicago—1.92 per 10,000 of population, as compared with an average of 3.24 during the previous decennium. A serious menace to child life early threatened from the one daily delivery of milk. Fortunately this was offset by the unusually low summer temperature—the coolest in thirty-four years. The action, however, led to increased activity among the various volunteer agencies for improving the quality of the milk supply and caused the commissioner personally to investigate the conditions of milk production in the country and the methods of shipment to the city. A great improvement has resulted in the former and the railroads are now interested in furnishing better facilities for handling in transit and for speedy transportation, thus "shortening the time from the cow to the baby." To the improved quality of the milk supply, from these causes, is largely due the reduction of mortality among children of the milk feeding period (one to five years of age) from the number in 1903. The cool summer, however, was a considerable factor in this saving of child life. Smallpox, which more than once threatened an epidemic spread from repeated importations into the city, has been combated with such vigilance and efficiency that its mortality is only 30 as compared with 47 in 1903. This vigilance and efficiency, made possible by the city council's emergency appropriation, have prevented any panic or undue excitement from the continued presence of the disease—a presence which must last as long as smallpox remains so widespread throughout the country as it now is. So, too, with diphtheria; the department supply of the antitoxine was cut off early in the year and the gravest results were apprehended. A personal visit and appeal of the commissioner to the New York health commissioner secured a renewal of former relations and an abundant supply of the specific has been had uninterruptedly since last February. The total deaths from this dreaded disease were only 396, or 218 fewer than last year and the fewest since 1878, when the population was less than one fourth that at present. Only five of the important causes of death show any increase over the numbers of last year. Except deaths from the acute intestinal diseases, which were sixteen more than in 1903, the causes showing increases were diseases over which sanitary effort and preventive medicine have as yet gained little or no control. These are apoplexy, 116; Bright's disease, 128; consumption, 234; and cancer, 59 more than in the previous year.

PRESSE MEDICALE.

February 4, 1905.

1. Instruction in Obstetrics at the Tarnier Clinic,
By Professor BUDIN.
2. Neurofibrillæ, According to the Method of S. Ramon y
Cajal.
By L. AZOULAY.

1. **Instruction in Obstetrics.**—Budin describes the advantages for teaching possessed by the Tarnier clinic and the course of instruction given there.

2. **Neurofibrillæ.**—Azoulay adds another contribution to the many he has already made regarding Cajal's method of staining and studying neurofibrillæ. In this article he deals with methods of staining not only the neurofibrillæ, but also of the separate nerve elements.

February 8, 1905.

1. New Apparatus for the Administration of Chloroform,
By F. JAYLE and G. BERRUYER.
2. Monosymptomatic Diphtheritic Paraplegia,
By C. AUBERTIN and L. BABONNEIX.

1. **Apparatus for the Administration of Chloroform.**—Jayle and Berruyer describe the various appliances invented for this purpose by Roth-Draeger, Vernon Harcourt, Ricard, and finally Reynier, together with the points of advantage possessed by the latter over the former.

2. **Monosymptomatic Diphtheritic Paraplegia.**—Aubertin and Babonneix claim that loss of the knee jerk may be the only symptom to indicate the presence of a postdiphtheritic paralysis, and they believe this to be caused by a very slight degree of poliomyelitis.

February 11, 1905.

1. Epidemiology of Cerebrospinal Meningitis,
By A. MANDOUL.
2. The Constituents of the Urine,
By MARCEL LABBE and HENRI LABBE.

1. **Cerebrospinal Meningitis.**—Mandoul observed in 1904 a small epidemic of five cases of cerebrospinal meningitis and has come to the conclusion that true prophylaxis against this disease consists in periodic lavage of the nasopharyngeal cavity in order to render it as aseptic as possible.

2. **The Constituents of the Urine.**—In this article the Labbés present a continuation of two articles which have previously appeared on the same subject. The nitrogenous substances, urea, uric acid, and the xanthic bases are dealt with. The conclusion drawn from the researches of the writers is that all the mineral and organic substances introduced into a physiologically normal digestive tract can be traced in the urine, that the constituents of the urine come not from dissimulation of the tissues, but from combustion of the alimentary material introduced into the organism, so that the urinary excretion serves as an index of the method of alimentation.

REVUE DE CHIRURGIE.

January 10, 1905.

By PONCET and LERICHE.
2. The Surgical Treatment of Scapula Alata,
By DUVAL.
3. Note on Anomalies of the Fingers, with Especial Reference to Valgus of the Little Finger,
By FÉRÉ and PERRIN.
4. Remarks on the Treatment of Cancer with the Röntgen Rays,
By DJÉMIL PACHA.
5. A Critical Study of Trendelenburg's Operation,
By VIANNAY.
6. Pathological Physiology of Pleural Hæmatoma
By CHASTENET DE GÉRY and FROIN.
7. External Cervical Œsophagotomy for the Treatment of Foreign Bodies in the Œsophagus,
By BALACESCO and COHN.
8. The Rational Treatment of Congenital Luxation of the Femur. A Theoretical Study,
By LE DAMANY.

1. **Ankylosing Tuberculous Rheumatism.**—Poncet and Leriche advise that the question of tuberculosis be ignored when arthritis has resulted in ankylosis. It is desirable, however, to eliminate acute articular rheumatism, traumatic arthritis, infectious arthritis with ankylosis, the different forms of chronic rheumatism, and the arthropathies of nervous origin, and recognize that the invasion of a bacillus is alone responsible for the condition. One must then determine whether the ankylosis is osseous or fibrous, and this can be done more accurately by means of radiography than by Malgaigne's method. A well ordered plan of treatment must then be adopted with especial reference to the presence of the bacillus of Koch. During the acute period salicylate of sodium or antipyrine should be administered in sufficiently large doses. The affected limb should be immobilized at an early period, and the effusion into the joint should receive revulsive treatment by means of the actual cautery, vesication, etc. The question of an orthopædic appliance should be considered as soon as ankylosis is definitely established. In deciding this question one will be influenced by the age of the patient, by his general condition, by the firmness of the ankylosis, etc. In deciding upon any form of treatment the possibility of recurrence of the trouble must be taken into account, and the indications must be clearly marked whether one decides upon immobilization under anaesthesia or resection.

4. **Remarks on the Treatment of Cancer With the Röntgen Rays.**—Djémil Pacha was enabled to reach the following conclusions: 1. Radiotherapy appears to have a favorable action on malignant tumors in general. 2. It results in cure when applied to superficial cancer, especially if the disease is in early stage. 3. It is important whether the apparent cures are permanent, and this question can be decided only after sufficient time has elapsed. 4. Radiotherapy is a palliative measure in cases in which the disease is extensive and in an advanced stage, and has a salutary influence upon the cancerous cachexia. 5. In inoperable

malignant tumors which cannot be subjected to surgical procedures radiotherapy is a valuable means of reducing to a minimum the sufferings of the patient.

5. A Critical Study of Trendelenburg's Operation.—Viannay observes that in the presence of a varicose condition of the internal saphenous vein an operation upon a single portion of the vein will prove futile unless there is a high resection in Scarpa's triangle. A better plan is to remove a number of segments of the vein, or to resect it entirely. The results which have been obtained by these operations justify their recommendation.

BERLINER KLINISCHE WOCHENSCHRIFT.

January 23, 1905.

1. Finsen Light Treatment of Lupus, By E. LESSER.
2. Echinococcus Disease of the Eyes, By R. GREFF.
3. Local Action of Suprarenal Substance, Pyrocatechin, and Spermin on the Circulation, By J. BAUM.
4. Acute Disseminated Hæmorrhagic Encephalomyelitis Under the Picture of Ascending Spinal Paralysis, By L. HINSMANS.
5. Cure of Two Cases of Bilateral Exophthalmos and One of Chorea by Removal of Adenoids, By B. HOLZ.
6. Camphor and Digitalis, By T. A. MAASS.

2. Echinococcus Disease of the Eye.—Greff proves that echinococcus disease of the eye occurs intraocularly, a fact which has hitherto been overlooked or doubted. He reports two undoubted cases. In both the cysts were simple and contained no daughter cysts, and in both the entire lenticular space behind the lens was filled by the cyst.

3. Action of Suprarenal Substance on the Circulation.—Baum concludes from his experiments that the anæmic effect of suprarenal substance are more powerful and more rapid, and last longer, the more normal the tissue containing the vessel is. The practical result is that the substance must be used only in normal or in slightly pathological tissues. It will not penetrate normal skin. There is a great chemical similarity between suprarenal substance and pyrocatechin, the latter acting in the same manner as the former upon small skin defects. The author believes that suprarenal substance acts on the principle of reduction. Experiments on frogs show that spermin acts as an accelerator of the pulse and as a dilator of the arteries and capillaries, antagonistic, therefore, to suprarenal substance in its local action.

4. Encephalomyelitis Hæmorrhagica.—Hinsmans reports the case of a previously healthy man who began to suffer from high fever, nervous disturbances, and later from weakness in the extremities. After paraplegia of the legs had appeared, the trunk became affected, then, in order, the upper extremities, the diaphragm, the muscles of the throat and pharynx, and finally the respiratory centre. The case presented every clinical evidence of acute ascending paralysis, but the autopsy showed it to be one of acute, disseminated, hæmorrhagic encephalomyelitis.

5. Adenoid Vegetations.—Holz reports two cases which he has classified as Basedow's disease mainly on account of exophthalmos. The author claims this symptom to have been due to adenoid vegetations, since it disappeared after their removal, recurred with a recurrence of the growths and disappeared again after their second removal. In the second case, a preliminary amygdalotomy had no effect upon the exophthalmos, but the removal of the adenoid vegetations permanently relieved the symptom. In a third case, a chorea in a child of seven years of age disappeared after adenoidectomy.

6. Camphor and Digitalis.—Maass says that camphor has a distinct vasodilator influence most noticeable in the regions of the jugular and femoral veins. Its direct action on the heart has also been proved of late. The author, in speaking of the well known influence of digitalis, says that a moderate contraction of vessels in the area controlled by the splanchnic nerve, takes place.

January 30, 1905.

1. Sprains of the Ankle (*To be concluded*), By PELS-LEUSDEN.
2. Intestinal Putrefaction in Catarrhal Jaundice, By F. BLUMENTHAL.
3. Two Rhachitic Dwarfs Delivered by Cæsarean Section, By HELMBOLD.
4. Chemical Questions as to Carcinoma, By C. NEUBERG.
5. Frequency of Primary Intestinal Tuberculosis in Berlin, By O. WAGENER.
6. Intestinal Diseases in Nurslings, By SALGE.

4. Chemical Questions in Carcinoma.—Neuberg has examined primary cancer tissue of the stomach and metastatic deposits in the liver for pentose contents, and finds a greater quantity of pentose in the metastasis than in the primary growth. It follows from this that the primary malignant cells of the gastric growth either undergo a degeneration in the liver or that new ferments are developed after the deposit of the cells in the liver. The author tested the effect of the altered liver tissue upon the lung tissue of the same individual and found that the juices from the hepatic cancer produced an abnormal fermentation of the pulmonary proteids.

5. Primary Intestinal Tuberculosis.—Wagener found, in 419 autopsies in Berlin, 20 cases of primary intestinal tuberculosis, cases in which the general somatic infection with the tubercle bacillus must be assumed to have originated in the intestines.

6. Intestinal Diseases in Nurslings.—Salge protests against diagnosis of gastrointestinal diseases in infants from the character of the stool alone, and urges consideration of the entire clinical picture of any given case. Diarrhoea, for instance, is often the result of overfeeding, such infants frequently suffering from eczema which recurs again and again despite treatment. In cases of cholera infantum in which the stools smell strongly of fatty acids, ingested fats are badly borne; but the main purpose of treatment

is to combat the collapse. The author does not believe in making diagnoses from the examination of the faces of children who are not seen clinically.

ZENTRALBLATT FUER GYNAEKOLOGIE.

January 21, 1905.

1. Paralysis of the Non-Pregnant Uterus,
By P. STRASSMANN.
2. Embryotomy,
By L. SEELIGMANN.
3. Prolapse and Gangrene of the Dilated Ureteral Ends,
By M. SIMON.

2. **Embryotomy.**—Seeligmann says that in cases of neglected transverse position, decapitation or eventration must be considered. In the absence of skilled assistants, the latter is the easier operation, all the necessary instruments being a scissors and a hook. First the thoracic and abdominal cavities are emptied, then the spinal column is broken with the hook and the body is delivered bent on itself. If this is not possible, the prolapsed arm is disarticulated and a version is done. The author reports two cases.

3. **Prolapse and Gangrene of the Ureteral End.**—Simon reports a case of this rare complication. A woman, fifty-two years of age, who had suffered for years from vaginal prolapse, discovered suddenly, while urinating, a tumor between the genitals, which proved to be the dilated, prolapsed left ureter entirely gangrenous. Simon operated on the patient, whose urine gradually cleared up, but continued to contain pus, probably due to pyelitis. But nine cases of the kind are to be found recorded.

January 28, 1905.

1. Winchel's Manual of Obstetrics,
By DOEDERLEIN.
2. A Case of Tetany Gravidarum,
By K. SCHMIDLECHNER.
3. A New Speculum for Perinaeorrhaphy,
By R. B. KEYSERLINGK.

2. **Tetany Gravidarum.**—Schmidlechner reports a case in a forty-four years old primipara who had severe attacks in the seventh month of pregnancy. Labor was induced, but had no appreciable effect and the patient died on the fifth day post partum during a severe attack. The autopsy showed nothing characteristic. The author goes carefully into the details of the disease, its classification, and treatment.

RIFORMA MEDICA.

January 21, 1905.

1. The Pathogenesis of Sensory Dissociation of Central Origin (*To be continued*),
By UGO BENENATI.
2. Diastatic Activity in the Bacillus of Tuberculosis, as a New Evidence of Its Relation to the Streptothrix,
By CLAUDIO FERMI.
3. Primary Trephining for Fractures of the Cranial Vault,
By ALDO CERNEZZI.
4. The Mode of Action and the Method of Controlling Some of the Antimicrobial Serums (*Concluded*),
By A. PALADINO-BLANDINI.

2. **Diastatic Action of the Tubercle Bacillus.**—Fermi found the newly discovered American

potato to be an excellent medium for the cultivation of the tubercle bacillus upon which the diastatic action of the germ in question could be studied. In previous papers the author showed that all the varieties of the streptothrix were endowed with noteworthy saccharifying properties. He was interested, therefore, in searching for the same property in the tubercle bacillus, as its presence would demonstrate another biological feature in common with the streptothrix. He made cultures of the tubercle bacillus upon a glycerin paste containing fifty per cent. of American potato, in which the absence of all reducing substances was first tested thoroughly. The paste was thoroughly mixed with the bacilli and placed in sterilized tubes, which were sealed and kept in the thermostat, together with control tubes containing simply the sterile paste. The tubes were placed horizontally, in order to give the paste as large a surface as possible. The results of this investigation proved that the tubercle bacillus has the power of diastatic action, and produces reducing bodies in starch. This effect was noted in all the tubes without any exceptions, and was absent in all the control tubes. The newly discovered diastatic action of the tubercle bacillus, according to the author, places this germ in still closer relation to the streptothrix than heretofore. The complete study of this question must be reserved, however, for further researches.

3. **Primary Trephining in Fractures of the Skull.**—Cernezzi pleads for the prompt employment of trephining in fractures of the cranial vault which require this operation. He reports a case of fracture of the left parietal region with considerable depression in which primary trephining produced an excellent result. He speaks of trephining as of an operation of ancient origin, recommended as early as in the Hippocratic era in the famous aphorism: *Nullum capitis vulnus leviter contemni debet*. During the Middle Ages, the decadence of science brought with it a gradual obsolescence of trephining, and only the tonsure of the monks remained as vestige of this operation. The Hippocratic traditions were revived, however, by Falloppius, and especially by Berengario da Carpi. Trephining was used with exaggerated zeal by Pietro Marchetti and Marco Aurelio Severino, who employed this operation even for syphilitic headaches, and naturally a severe reaction ensued against such practices, especially in the work of Boyer, Desault, and Bichat. The high mortalities of this operation obtained by Fritz, Pirogoff, and Otis in the first half of the nineteenth century also served to discredit trephining. It was only with the advent of modern asepsis that the operation entered upon its modern status. Zanelli, in 1877, advocated immediate trephining in all fractures of the cranium which gave symptoms of compression, and the same view was held by Sédillot, Lucas-Championnière, Trélat, and von Bergmann. The latter advocated immediate trephining in all compound fractures of the cranial vault with or without cranial complications. In 1886 Seydel demonstrated the innocuousness of this operation when per-

formed aseptically, and lamented the lack of confidence in trephining held by practitioners of his day. Luebeck and Wagner, and later on Robson and MacGill (? McGill) in England; Ceci in Italy, and Quénu in France, reported brilliant results with this rehabilitated therapeutic procedure. Since 1890 the work of Klemm, Koehler, and Broca and Manbrac has definitely established the operation in its present status. The chief point to remember in connection with the indications of trephining, a point which cannot be too strongly emphasized, is that the presence of but slight visible injuries to the soft parts is not a reason for confining one's self to expectant treatment. The author has seen several cases in which septic infection of the cranial cavity followed in such patients after a short period of expectant and antiseptic treatment. Trephining in his opinion should be done in depressed fractures whether or not there are signs of compression. A wide opening of the wound, a thorough cleaning, the removal of all fragments, and thorough drainage should be the chief features of all trephining operations.

4. Mode of Action of Antimicrobial Serums.—

Paladino-Blandini agrees with Metchnikoff that the artificial immunity conferred on animals in virtue of injections of antimicrobial serums is an active immunity, induced through leucocytosis. He believes, also, that in testing the efficiency of a serum one should inject simply the minimum lethal dose of the culture; at most twice this dose, and one should always use germs of high virulence in the experimental infections in animals.

January 28, 1905.

1. Latent Echinococcus of the Liver. Hidden Echinococcus (*To be continued*), By C. BARNABEL.
2. On Cancerous Cirrhosis of the Liver, By ELMARO ROLLINO.
3. Late Hereditary Tabes Due to Congenital Syphilis, By MARIO BARTOLOTTI.
4. On the Pathogenesis of Sensory Dissociation of Central Origin (*To be continued*), By UGO BENENATI.

2. The Origin of Cancerous Cirrhosis of the Liver.—Rollino concludes from a study of three cases that the prolonged irritation produced by chronic gastroduodenal catarrhs induces a retarded flow of bile and a slow interstitial hepatitis, which in these cases was followed by cancer, the contributing causes having been heredity and alcoholism.

3. Late Tabes Due to Hereditary Syphilis.—Bartolotti reports two cases of tabes which occurred in adults as the result of hereditary syphilis. In one patient the locomotor ataxia did not develop until after the fortieth year. Inunctions of mercury had excellent effects in this case. In the second patient the disease began when he was 25 years old and was arrested in the incipient stage. The author calls attention to the necessity of considering hereditary syphilis as one of the causes of locomotor ataxia even at an advanced age. Usually alcohol, etc., is blamed in such patients, and hereditary syphilis is thought of only in younger persons affected with tabes.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

March 4, 1905.

2. The Sanitary and Moral Prophylaxis of Venereal Diseases, By PRINCE A. MORROW.
3. What is the Right Attitude of the Medical Profession Toward the Social Evil? By HOWARD A. KELLY.
4. Syphilis as a Disease Innocently Acquired, By L. DUNCAN BULKLEY.
5. Syphilis Affecting Infant Mortality, By HENRY ENOS TULEY.
6. Acute Yellow Atrophy of the Liver, By H. GIDEON WELLS and PETER BASOE.
7. Delirium as a Symptom of Hysteria. Report of Four Illustrative Cases, By THEODORE DILLER.
8. The Relation of States of Apprehension to Cardiac Disease, By WILLIAM RUSH DUNTON, JR.
9. Spastic Diplegia Following Pertussis, By J. H. W. RHEIN.
10. Acute Intestinal Surgery, with Remarks on Technics, By JOHN YOUNG BROWN.
11. Valedictory Address at Johns Hopkins University, By WILLIAM OSLER.
12. Immunity. Chapter VI.

2. Prophylaxis of Venereal Diseases.—Morrow holds that effective prophylaxis against venereal diseases can be hoped for only through education. This will lead to two important results: The establishment of adequate hospital facilities for the free treatment of acute venereal diseases and the development of the feeling of individual moral responsibility. Venereal diseases differ from all other contagious diseases in that they are usually transmitted voluntarily. It is for this reason that it is important that the moral responsibility of the transmitter of the disease should be emphasized.

3. The Medical Profession and the Social Evil.—Kelly holds that the only remedy for the social evil problem is an active personal campaign, inspired by a profound sense of personal responsibility. The author has this to say regarding government control: "As for myself, and I trust I speak for all in this professedly Christian land, I would declare: 'We cannot consent to sanction of evil that good may come from it.' If appealed to to be practical, we answer that we cannot afford to be 'practical' at the sacrifice of principle; we will fight evil wherever we see it, and under all circumstances we will oppose the debasement of the public standards of right and morality. This we will do in entire confidence that in spite of all appearance the right so upheld will in the end prove victorious. Pure laws are the heritage we would leave to our generations yet unborn, and let not those who are caught in a final cataclysm of evil, point back to this day of boasted civilization as the memorable era when the public standards of right were first debased."

4. Syphilis.—Bulkley holds that since syphilis is not necessarily a venereal disease it should be treated as any other form of contagious disease so far as the health authorities are concerned. A sharp distinction should be made between the

problem of syphilis and that of prostitution. The author concludes: "The first step, I believe, is to recognize and place syphilis among other contagious diseases, under the control of health boards, and as public sentiment is aroused to the advantage of this proceeding, it will be easier to advance step by step in the restraint of the disease. If it were placed on the same footing as smallpox, scarlatina, and diphtheria, and if it were made a misdemeanor to communicate syphilis wittingly, a great step would have been taken toward diminishing the frequency of the disease and consequently its innocent infection."

6. Acute Yellow Atrophy.—Wells and Bascoe report in detail, clinically and pathologically, four cases of acute yellow atrophy of the liver studied in the pathological laboratories of the University of Chicago and Rush Medical College. The object in placing the cases on record is to furnish material for those interested in the study of this not uncommon disease.

BOSTON MEDICAL AND SURGICAL JOURNAL.

March 2, 1905.

1. Certain Aspects of Bile Duct Disease,

By JAMES G. MUMFORD.

2. Ptosis of the Abdominal Organs with Special Reference to the Kidney:

(a) Importance of Considering Ptosis of Other Organs in the Treatment of the Kidney,

By M. P. SMITHWICK.

(b) Treatment of Ptosis of Abdominal Organs by Abdominal Supporters,

By WILLIAM H. SMITH.

(c) The Actual Results at the Massachusetts General Hospital, Following Operative Treatment,

By F. G. BALCH and J. R. TORBERT.

(d) Results of Surgical Treatment of Movable Kidney at the Boston City Hospital,

By PAUL THORNDIKE and L. R. G. CRANDON.

1. Bile Duct Disease.—Mumford devotes his paper to an attempt to prove the soundness of the following rules which he urges should be observed in operating for bile duct disease: (1) Remove stones; for if left behind they are very sure to cause subsequent disturbance, and we know conversely that after the thorough removal of stones their recurrence is almost unknown. (2) Remove so far as possible all disorganized, degenerated, and permanently crippled tissue; for such tissue, when left behind, may become the nidus for subsequent inflammation, stone formation, and a return to the invalid condition. (3) Drain, for without drainage we have no certainty of the removal of infectious material.

2. Ptosis of the Abdominal Organs.—(a) Smithwick emphasizes the importance of not concentrating the attention too closely on a floating kidney and holding it alone responsible for all the symptoms observed. Incidentally he calls attention to the fact that visceral ptosis may be the consequence and not the cause of nervous exhaustion. (b) Smith has used two general forms

of support: (1) The plain abdominal belt and (2) the well padded and fitted corset-like belt. The latter will, generally speaking, give the best results. He concludes: "Without the intelligent cooperation of both patient and physician, but little benefit will follow the use of abdominal supporters; where this cooperation can be secured and a properly fitted belt is made and properly worn, I believe relief is to be obtained in certain cases, especially of nephropothesis with Dietl's crises. In some cases I believe this relief will be permanent." (c) Balch asserts that, on the whole, the results obtained from nephrorrhaphy at the Massachusetts General Hospital have not been very encouraging. In private practice the final results should be much better, but cases should be selected with very great care. (d) Thorndike summarizes his paper thus: From 40 per cent. to 80 per cent. of all women have a palpable or even movable kidney. The causes of the condition seem to be lack of general muscular tone, anatomical peculiarities, or increase in the weight of the kidney, one or all. The symptoms are—a sensation, subjective or objective, of a mass moving from the flank into the abdomen, crises of kidney pain, a variety of nervous derangements from nervous dyspepsia to neurasthenia. The diagnosis is made on the presence of the mobile tumor, the symptoms just given, and by ruling out kidney stone, new growth, and gallstones. The treatment should be, first, mental; second, development of abdominal and back muscles; and last, if necessary, and no contraindication exists, fixation of the kidney by operation. The prognosis, after an operation, which is technically proper, is for perfect cure.

MEDICAL NEWS.

March 4, 1905.

1. The Equilibrium Between Infection and Immunity as Illustrated in the Tonsillar Crypt,

By JONATHAN WRIGHT.

2. Multiple Neuritis in Wood Alcohol Poisoning,

By SMITH ELY JELIFFE.

3. Appendicitis, as a Visceral Manifestation of Erythema Exudativum Multiforme,

By JAMES S. CHENOWETH.

4. Short and Easy Methods of Arriving at Good Results in Diseases of the Ear and Upper Air Tract, Illustrated by Recent Cases,

By W. SOHIER BRYANT.

5. The Diagnosis of Malaria by the Finding of Pigmented White Corpuscles in Unstained Blood Films,

By J. R. CLEMENS.

6. Psammoma of the Maxillary Sinus,

By JOHN C. MUNRO.

2. Multiple Neuritis.—Jelliffe reports three cases of multiple neuritis due to the drinking of wood alcohol. Optic neuritis due to this cause is fairly frequent, and has received a fair amount of attention. Multiple neuritis must be rare, since this author has not been able to find references to a single case. This is probably due to the fact that patients are apt to die so quickly that a peripheral neuritis has not time to develop.

2. Appendicitis.—Chenoweth reports two cases of appendicitis due to the local manifesta-

tions of erythema exudativum multiforme. He believes that too much stress has been placed on the bacterial causation of appendicitis and too little on its possible constitutional origin. The not infrequent visceral symptoms of erythema exudativum multiforme must not be mistaken for an appendicitis.

5. **The Diagnosis of Malaria.**—Clemens has tested, with over five hundred observations, the dictum of Mason that: "The finding of pigmented white corpuscles is absolutely pathognomonic (of malaria) and a diagnosis may be made on that finding alone." He asserts that the statement is correct. The method is so rapid and accurate that it should receive general recognition.

MEDICAL RECORD.

March 1, 1905.

1. The Digestion of Caseins, and Its Relation to Certain Problems in Infant Feeding,

By THOMAS S. SOUTHWORTH.

2. A Study of Fifteen Cases of Erysipelas Treated by Injections of Antistreptococcus Serum, By J. C. AYER.

3. Chronic Rheumatism, Gout, and Other Uric-Acid Diatheses Treated by the X Ray, High Frequency Currents, and Vibratory Massage, By SINCLAIR TOUSEY.

4. The Prosthetic Treatment of Fracture of the Mandible,

By FRANCIS ASHLEY FAUGHT.

5. Acute Intussusception in an Infant; Resection of Gangrenous Intussusceptum; Murphy Button Anastomosis; Recovery, By EDWARD W. PETERSON.

6. The Use of Extract of Dichondra as a Bactericide in Diphtheria,

By M. ARAMIAN.

1. **Infant Feeding.**—Southworth discusses the digestion of caseins in the infant stomach from the standpoint of the most recent studies of stomachic digestion in animals. Woman's milk is not alkaline, as was formerly taught, and caseinogen is a fiction of the older chemists and physiologists. Stomachic digestion, in the young, according to present teaching, may be summarized as follows: The first secretion of the stomach of the young is the ferment rennet. The rennet ferment acts upon the calcium casein of the milk, forming a soft clot which is called calcium paracasein (junket). If no acid is present this paracasein clot may pass on into the intestine where it is readily digested by the pancreatic and intestinal secretions. The pepsin secreted by the stomach will not attack calcium paracasein in the absence of acid. But when hydrochloric acid begins to be secreted by the stomach this reacts with the calcium paracasein formed by the action of the rennet ferment, making first free paracasein and then a definite chemical compound known as hydrochloride of paracasein which is fitted for gastric digestion and is now readily attacked by pepsin, and true stomach digestion begins. The author attempts to outline how the feeding of bottle infants should be conducted so as not to conflict unduly with modern chemistry.

2. **Erysipelas.**—Ayer concludes: (1) That the administration of antistreptococcus serum shortens considerably the course of uncomplicated attack of erysipelas. (2) That it tends to inhibit

extension of the disease. (3) That it has a strikingly beneficial effect upon the general condition of the patient, reducing the temperature, pain, and discomfort incidental to the disease. (4) That it rapidly reduces the pathological leucocytosis. (5) That it prevents or suppresses febrile albuminuria. (6) That its use is attended with no danger, even in large doses. (7) That the only disagreeable symptom referable to the serum observed by the writer is a transient eruption which occasionally occurs at the site of the injection. (8) That the efficacy of the serum treatment is in direct ratio to the length of time which has elapsed between the onset of the disease and the first injection of serum.

4. **Fracture of the Mandible.**—Faught recommends treating fractures of the mandible by cementing to the teeth of the fractured jaw a metal splint constructed to accurately fit the teeth when perfect reduction has been obtained. The author describes in minute detail the various steps in the manufacture of the splint. Any dentist ought to be able to do the work satisfactorily by following the author's directions.

5. **Acute Intussusception.**—Peterson reports in detail the case he describes in the title of his paper. The infant was four months old. The button was passed on the fourth day.

6. **The Extract of Dichondra.**—Aramian asserts that the extract of dichondra, one part, in glycerin three parts, is a true bactericide for the germ of diphtheria. The mixture should be applied locally, and can be used without fear, as it is non-toxic. Cultures from the throats of diphtheritic patients will prove negative for the diphtheria bacillus after three or four days' treatment with the drug advocated. The drug is purely bactericidal, and is not in the least sense antitoxic.

AMERICAN MEDICINE.

March 4, 1905.

1. Mucous Colic, By ROBERT COLEMAN KEMP.

2. Some New Views of Infant Feeding and Their Practical Application, By HENRY DWIGHT CHAPIN.

3. The Mortality of Pneumonia in High Altitudes, By MAJOR CHARLES F. KIEFFER.

4. Landry's Paralysis, with a Report of a Case, By CHARLES F. WILEY.

5. Case of Puerperal Tetanus with Recovery, By JOHN F. RODEERER.

6. Poisoning by Potassium Bichromate, By FRANCIS EUSTACE FRONCZAK.

7. City Dust and Patent Medicine Advertisements, By ROBERT HESSLER.

1. **Mucous Colic.**—Kemp defines mucous colic as a "condition characterized by the excessive production of mucus in the colon, by attacks of painful spasms of varying degrees of severity and frequency, accompanied or followed by the expulsion of mucus in gelatinous masses, or in the form of tubular casts, or in tape-like pieces or strings, and furthermore characterized by anomalies of the gastrointestinal functions and by various nervous symptoms." The ætiology of

the condition is generally conceded to be poorly understood. The author records a number of observations which lead him to believe that its chief ætiological factor is ptosis of the colon with associated gastropnoia. The treatment is therefore of two kinds: Medicinal and surgical. The latter need not be resorted to except in very exceptional cases. The author describes at length the treatment of the condition from the internist's point of view. He has a high opinion of the efficiency of Rose's belt.

2. **Infant Feeding.**—Chapin emphasizes some of the newer teachings regarding infant feeding. It is now well established that the alkalinity or acidity of milk cannot be tested by litmus paper. Cow's milk is not acid, as compared with woman's milk. The effect of adding an alkali to an infant's milk is this: The rennet ferment of the stomach will not curdle the milk in the presence of alkalis, and no stomach digestion can take place in the absence of acid; so as long as there is alkali in the food, digestion will not take place in the stomach, but the food will pass into the intestine in a fluid condition. Curdling of the milk in the stomach is indeed prevented, but at the expense of the stomach's functional activity. By adding gruels to an infant's milk we prevent the formation of hard curds in the stomach, but still leave work for the stomach to do. This latter method of feeding is the one advocated by the author.

3. **The Mortality of Pneumonia.**—Kieffer has studied the records of 127 cases of pneumonia that have occurred at Fort D. A. Russell, Wyoming, during the past thirty-eight years. The post is situated at an elevation of 6,195 feet above sea level. The author would not deduce too much from so few cases. Yet, so far as they go, they seem to show that altitude has no influence on the mortality of pneumonia.

4. **Landry's Paralysis.**—Wiley reports one case which did not die. The temperature did not go above normal after the forty-third day of the disease. The patient, at the time the paper was written, had not yet regained the use of his lower extremities. The author reviews briefly the usual clinical course of Landry's paralysis and inclines to the belief that the affection is of an infectious nature.

5. **Tetanus.**—Roderer gives the following summary of his case of puerperal tetanus: The first symptoms of tetanus appeared on June 7th, ten days after the birth of the child. Eighteen days later (June 25th) she had entirely recovered from tetanus. From June 7th until June 11th she had only tonic spasms. The clonic spasms began on June 12th and lasted until the evening of June 24th, during which time she had at least 1,500 convulsions. During the first four or five days all the spasms, which were very severe, were accompanied by intense pain. After that the convulsions were not painful, nor were they so severe. Tetanus antitoxine was administered on 32 different occasions. In all, 660 c.c. were given, or to speak more correctly, 132,000,000 immuniz-

ing units. The injections were given under the skin of the abdomen or sides of the thorax. Chloral and morphine were also used in the treatment of the case.

INTERNATIONAL JOURNAL OF SURGERY.

February, 1905.

1. Some Common Deformities and Their Prevention, By BOWDEN.
2. The Chambers Suture in Abdominal Surgery, By CHAMBERS.
3. The Temperature as a Guide to the Existence of Suppuration, By ALLEN.
4. Practical Gynecology, By SELLMAN.
5. Practical Treatment of Diseases of the Eye, By COOKE.

3. **The Temperature as a Guide to the Existence of Suppuration.**—Allen draws the following conclusions: 1. Chronic suppurative processes are very frequently unattended by fever. 2. Acute suppurative processes are frequently unattended by fever, therefore in a given case the absence of fever must have little weight, by itself, in excluding the possibility of suppuration. 3. Since a rise of temperature above 100° F. occurs in about two thirds of all aseptic cases, the presence of fever alone must have little weight in making a diagnosis of suppuration.

AMERICAN JOURNAL OF OBSTETRICS.

February, 1905.

1. The Pathological Anatomy and Pathogenesis of the Toxæmia of Pregnancy, By EWING.
2. Eclampsia with Report of Cases, By ALLEN.
3. The Treatment of the Obstetric Hemorrhages, By BRODHEAD.
4. Pyelitis Complicating Pregnancy, By SPALDING.
5. A Typical Case of Tuberculous Peritonitis, By MANTON.
6. Three Specimens of Exencephalia, By LEWIS.
7. Some Conclusions After Operating for Two Years on the Pelvic Diseases of Insane Women, By BROWN.
8. Pelvic Inflammation. A Discussion of One of the Moot Questions Relating Thereto, By DUNNING.
9. Fibroid Tumors and Pregnancy, By MARX.
10. A New Operation for Cystocele, By WOOD.

1. **Toxæmia of Pregnancy.**—Ewing offers an interesting paper on this very important subject. He states that at present this condition may be regarded as a functional disturbance of the liver, usually accompanied with anatomical lesions of that organ, and with functional disturbance and anatomical lesions of the kidneys and other organs. The kidney disease may become pronounced only when the poisons resulting from the failure of oxidation in the liver cause degeneration, congestion, and exudative inflammation of these organs. It may, therefore, be far advanced before albuminuria appears. There may be fatal cases with minimal lesions of the liver. The hepatic lesions follow the disturbance of function, but there are several steps between the loss of oxidizing capacity, and the hydrolysis, fatty degeneration, and necrosis of the liver cells. Many factors are concerned in the disturbance of nitrogenous metabolism such as the retention of

substances usually eliminated with menstruation, the increased metabolism required in the growing fetus, the influence of thyreoid and parathyreoid, etc. Two important observations upon autopsy subjects were the distended intestine containing saline solution which had not been absorbed, and the remarkable concentration of the blood. The inference from these conditions is that the blood requires dilution, but it should be by infusion with saline solution rather than by rectal enema. Pathological study also shows the absence of any necessarily fatal character in the disease. We are dealing primarily, at least, with a disturbance of function, not with a hopeless anatomical lesion nor an uncontrollable bacterial infection. Ringer's fluid is recommended for infusion, rather than the usual normal salt solution.

2. **Eclampsia.**—Allen offers the following conclusions: 1. Eclampsia is due to a toxine which probably has its origin in the liver. 2. Its origin is maternal rather than foetal. 3. Premonitory symptoms are always present. 4. The most constant and important premonitory symptom is frontal headache. 5. The diagnosis of toxæmia of pregnancy should be made early, and this can generally be done if the patient is under observation. 6. The mortality should not exceed 20 per cent. 7. The premonitory symptoms should be treated until they are proved ineffective. The uterus should then be emptied, and this may be the only way to stop the progress of the disease. 8. Delivery should be accomplished as rapidly as is consistent with cleanliness and the integrity of the soft parts. From 300 to 700 cubic centimetres of blood should be drawn, and then 500 to 1,000 cubic centimetres of salt solution should be infused according to the quantity of blood withdrawn and the character of the pulse. It may be necessary to repeat this operation: Morphia gr. $\frac{1}{4}$ may be given to relax the muscular system, and Croton oil, 1 to 2 drops, in olive oil 1 to 2 drachms, followed by magnesium sulphate, half an ounce, in saturated solution until free purging has resulted. 9. The diet should be limited to milk and water. 10. Other symptoms should be treated as they arise.

9. **Fibroid Tumors and Pregnancy.**—Marx concludes his paper as follows: 1. Every fibroid, with few exceptions, which develops during the child bearing period, should be attacked by surgical means. 2. Those fibroids which are beyond the dilating zone of the uterus should be carefully watched. Every complication during pregnancy which depends upon the fibroid should warrant a surgical attack, or should at least cause us to consider the question of emptying the uterus. 3. The apparently safe tumors should be watched during labor. Resultant complications such as hæmorrhage and delayed labor should be met energetically as they arise. Tumors which block the bony passage, and cannot be displaced should be enucleated per vaginam when possible; or Cæsarean section should be performed and be followed by hysterectomy. 4. Sloughing and necrosis of a puerperal fibroid must not be mistaken

for retained secundines. The doubt must be eliminated by exploration with the asepticized hand. The curette should not be employed on account of the possibility of injuring the capsule and subsequent sepsis. 5. Sloughing and necrotic fibroids should be removed either by enucleation or hysterectomy.

ANNALS OF SURGERY

February, 1905.

1. Acid Intoxication. Its Significance in Surgical Conditions, By KELLY.
2. Gall Bladder and Biliary Duct Surgery, By STEELE.
3. Volvulus of the Jejunum, By SCUDDER.
4. Operations on the Lower Ends of the Ureters by the Inguinal Extraperitoneal Route Under Local Anæsthesia (Cocaine), By SAMPSON.
5. Primary Urethral Calculus, By WOLF.
6. Case of Bone Transference, By HUNTINGTON.
7. Contrecoup Fracture of the Sternum, By TAEROWSKY.
8. Fracture of the Carpal Scaphoid with Habitual Dislocation of the Central Fragment, By RUSS.
9. Interscapulothoracic Amputation, By COBB.
10. Symmetrical Inflammation of the Epiphyseal Beak of the Tibia, By WINSLOW.

1. **Acid Intoxication.**—Kelly states that he formulates no definite theory for the causation of this condition. He merely presents a series of cases which are identical with those which have been reported by other observers. Our knowledge as to the cause of the symptoms as well as of the occurrence of acetone and diacetic acid in the urine is yet in its infancy. It is not due to acetone circulating in the blood, nor is the quantity in the urine an index to the severity of the condition. It is not yet proven whether the symptoms are due to a toxic substance acting on psychomotor centres or to pressure on these centres. There is some toxæmia, but we do not know whether it is due to the presence of volatile fatty acids, to the rapid destruction of proteid matter, or to the rapid elimination of alkalies. This condition has usually been considered as fatal in its tendency, but the author's cases show that it exists in a mild form in a variety of instances. There is need of further experimental and clinical investigation of the subject.

4. **Operations Under Local Anæsthesia.**—Sampson summarizes his article as follows: 1. Advantages of a general anæsthetic are that the patient is unconscious, relaxed, the operation requires less time and is easier than with a local anæsthetic. 2. But in certain cases a general anæsthetic is contraindicated, a percentage of cases die from that cause alone, it lowers the resistance of the patient, it is often unpleasant to take, and unpleasant to recover from. 3. If an operation is not painful why give a general anæsthetic, or for a long operation why not use a temporary general anæsthetic like nitrous oxide or a local anæsthetic like cocaine for that portion of the operation which may cause pain? 4. Pathological conditions of the lower ends of the ureters usually impair the functions of those organs and of the kidneys as well, and therefore may contraindicate

the use of a general anæsthetic. 5. In four very long operations performed by the author the most noteworthy symptom was fatigue. 6. Anything which causes traction of the parietal peritoneum is painful. 7. The extra peritoneal route is a desirable way of reaching the lower ends of the ureters, is less painful, and offers less chance of infection, and less shock. 8. Two incisions are practicable, the gridiron incision lateral to the rectus muscle similar to the McBurney incision, but a little lower, or a longitudinal incision through the rectus.

LANCET.

February 18, 1905.

1. The Hunterian Ovation, By J. TWEEDY.
2. Functional Mental Disorders, By G. H. SAVAGE.
3. The Early Symptoms of Insular Sclerosis, By E. HOBHOUSE.
4. Sabouraud's Method of Ringworm Treatment, By J. L. BUNCH.
5. Some Cases of Urethral Stricture Complicated with a Prostatic False Route or Passage; with Remarks, By R. HARRISON.
6. Colles's Fracture and Other Fractures and Disjunctions at the Lower End of the Radius and Ulna, By A. FULLERTON.
7. A Case of Acute Hæmorrhagic Pancreatitis: Operation; Recovery, By T. C. L. JONES.
8. The Histopathology of Seborrhœa, Seborrhœic Dermatitis, and Psoriasis, By R. W. BRUNACOMBE.
9. A Case of Endocarditis with Pericarditis Following Scarlet Fever; Treatment by Antistreptococcic Serum; Recovery, By A. R. SPENCER.
10. Traumatic Lumbago, By R. ROMER.

2. **Functional Mental Disorders.**—Savage, in the Lettsomian lecture, says that there are many cases in which disorder of mental function cannot be directly associated with material change in the brain or nervous system. Many cases may depend upon alterations of nutrition of a temporary character in the nerve centres, central or peripheral. Besides this there are certain disorders which depend upon the disharmony existing between the nervous system of the patient and his surroundings. Such disharmony may be original and ineradicable and is met with in certain persons who seem to have been born out of due time, being only suited to primitive states of civilization. There may also be misjudgments of parts of the nervous system, want of will or directing power—want of proper adjustment of what have been called the functions of mind. In obsessions there may exist perfect knowledge and all the necessary constituents of the mind, yet their association may be morbid, and the result may be unreasonable and impulsive action, unreasonable belief, or obsessions of ideas. Insanity, mental disorder, depends as much on the surroundings as on the individual's bodily condition.

3. **Insular Sclerosis.**—Hobhouse discusses the early symptoms of insular sclerosis from the point of view of the general practitioner. The disease is of great importance for three reasons: 1. It is the commonest of all the chronic diseases of the

central nervous system. In five years the writer has seen nine cases in which he was absolutely sure of the diagnosis, and eight more in which the diagnosis was doubtful. 2. Owing to the great diversity of its symptoms it may come first in the early stage under the notice of any physician, whether he be a surgeon, an aurist, a laryngologist, a gynæcologist, etc. The majority of cases begin in one of two or three ways. Most patients first complain of weakness of one or both legs, or of nervousness and trembling. Many go first to the ophthalmic surgeon. Of the sixteen cases on which the author's paper is based, three began with purely ocular symptoms—ophthalmoplegia, failing vision, diplopia, etc. In all the others loss of power or sensation was the first symptom. Menorrhagia is a very frequent symptom in women. 3. The disease is by no means easy to recognize in its early stages, and is extremely apt to be confounded with hysteria, if, indeed, it be not more correct to say that hysteria is not rarely the prelude to insular sclerosis. Once the diagnosis is made, a good deal of harm to the patient is avoided, by not treating them as hysterical and not insisting on exposing them to the ridicule or reproaches of their family. The transitory nature of the symptoms is the most misleading thing about the early stage of the disease. The symptoms may come and go with startling suddenness. Many of the patients also have a typically hysterical manner. Babinski's toe phenomenon is the most valuable of all the reflex symptoms of the disease. The slower the onset of symptoms the more hopeful is the prognosis as to remissions and the less likely is any given attack to be finally crippling to mind or body. The fact that the earliest symptoms are cerebral does not necessarily imply that those will be predominant later. In two cases ocular symptoms came first, but the brain and the upper cord were comparatively little affected, whilst the paraplegic symptoms had been prominent for years.

4. **Ringworm.**—Bunch warmly recommends Sabouraud's method of treatment of ringworm of the scalp by means of x rays. All chemical and antiseptic methods fail because the root of the hair is inaccessible. Radiotherapy causes the hair to fall out, but hitherto it has not been successful in ringworm, because of the absence or imperfect measurement of the quantity and quality of the rays applied. Sabouraud has worked out a successful method of measurement of the rays, and as practised by him it is painless, the actual time necessary for the treatment is short, and the diseased hairs fall out at a definite interval after application of the x rays, and are replaced after a certain time by a growth of healthy hair. The writer goes on to describe the apparatus used and how the rays are applied to the diseased area.

6. **Colles's Fracture.**—Fullerton's article is based upon a series of sixty-nine cases of fractures and disjunctions of the lower end of the radius and ulna. In dorsal displacements two splints should be applied, the anterior one not coming below the fracture, and the posterior one

being so padded that the hand is flexed to an angle of 45° . If there is impaction it must in all cases be first broken down if possible, and the parts must be firmly pushed into position before the splints are applied. Splints should not be kept on longer than two weeks and the patient should be early encouraged to use his fingers.

7. Acute Pancreatitis.—Jones reports a case of acute pancreatitis occurring in a woman aged twenty-six years, coming on with symptoms of intestinal obstruction. A diagnosis was made of some gastric lesion (perforation) and the abdomen was opened, when a large quantity of bright blood and serum was liberated. The pancreas, which was three times the normal size, was discolored, oedematous, and hæmorrhagic. It was incised and packed with gauze, which checked the hæmorrhage, and the patient made a good recovery. When the packing was removed pancreatic juice was discharged for some time.

8. Seborrhœa.—Brunacombe, in this paper, attempts to demonstrate the close connection between seborrhœa, seborrhœic dermatitis, and psoriasis by means of a study of the histopathology of these conditions. In seborrhœic dermatitis he thinks that the condition is due to atrophy of the sebaceous glands, and formation of a horny material in the hair follicles. Microorganisms play only a secondary part.

9. Endocarditis.—Spencer reports the case of a boy, aged five years, who, after an attack of scarlet fever, developed endo and pericarditis. His condition became very critical, and antistreptococcus serum was used with excellent results. From a study of the literature of the serum treatment of endocarditis, the author concludes: 1. The earlier the treatment is begun the better the hope of recovery. 2. It is undesirable to wait for a positive confirmation of the diagnosis, such as embolism, before beginning treatment. 3. The size of the dose should be regulated, not by the age of the patient, but by the gravity of his condition.

10. Traumatic Lumbago.—Romer reports ten cases of traumatic lumbago. The history is that of some definite, though frequently slight sprain of the back, after which the pain does not quite disappear, and as time goes on becomes more persistent. Lumbar stiffness increases and a condition arises similar to chronic lumbago. The pain is usually referred to one particular spot. On examination the lumbar muscles are usually found to be wasted, while on the affected side they are rigid and contracted. Early spinal caries must be excluded. The treatment consists in stretching the affected muscles under an anæsthetic, and rupturing any adhesions.

6. A Case of Long Standing Constipation, By H. GREY.
7. Ergot and Arsenic in Chorea, By C. RIVIÈRE.

2. Visceroptosis.—McCallum tells us that the displacement downward of any of the viscera is without symptoms, so long as the patient is in good physical condition. The disease comes to our notice in association with neurasthenia, and no mechanical replacement can cure the neurasthenia. On the other hand, a cure of the neurasthenia goes far to make a symptomatic cure of the visceroptosis. Over ninety per cent. of cases of neurasthenia in the female depend upon visceroptosis. It is less prevalent in male neurasthenics. The important clinical ætiological factors are bad standing posture, badly fitting garments, imperfect use of the lower zone of the thorax, the absence of fat, and the want of tonicity in the abdominal musculature leading to defective intraabdominal pressure. The symptoms, when well marked, are practically those of neurasthenia with or without direct local distress. Some form of gastric disturbance is the one usually complained of. Pain may be felt anywhere, but is most frequently referred to the small of the back. The crisis of movable kidney has been taken for appendicitis, and intermittent hydronephrosis for ovarian tumor. Gynaecologists are coming to recognize that prolapse and displacement of the uterus is but part of the general visceroptosis. There is usually a mild form of secondary anæmia. Presenility is occasionally found, and this may be attended with early arteriosclerosis. The most constant symptom is emaciation or malnutrition. The skin is markedly free from fat, and devoid of elasticity. Dermography is a stigma of the disease. The abdominal musculature is flabby and atrophied, and there is absence of the stomach resonance in Traube's semilunar space. In many cases the tenth rib floats. The inflation of the stomach and colon should be carried out, after the solid organs have been palpated. The Weir-Mitchell treatment when applied to visceroptosis is curative, stress being laid upon the following features: a. Recumbent posture in bed, if possible without pillows, for from four to six weeks. b. Cool baths before massage to get muscular relaxation. c. General massage, with an attempt to build up the abdominal wall. d. Raising up the thorax, so as to expand its lower zone, and thus make room for the viscera. e. Proper feeding. f. Training of mind and body. The muscular tone of the levator ani in bringing the pelvic viscera to their normal position. The tone of this muscle is largely dependent upon the tonus of the lower half of the abdominal wall.

3, 4. Recurrent Vomiting in Children.—Shaw and Tribe state that recurrent, cyclical, fitful, or periodic vomiting in children, begins generally after the first year of life, and may persist until the eleventh year. In many cases the symptoms

pass off altogether, or they may develop into migrainous attacks. Very often there is a prodromal stage, during which the child shows general malaise: then the vomiting begins, whatever food is taken being returned, and this is succeeded by the ejection of mucus, bile, and even blood. The attacks may last several hours or days, and occur from once a month up to once a year. Constipation is common and may resist all treatment. Pain is almost entirely absent; thirst is very common and very intense; the appetite is quite lost, the tongue coated, the breath of a peculiar odor attributable to acetone, and the urine may contain acetone and indican. The abdomen is usually greatly retracted or flattened in prolonged cases. When the attacks first occur it may be very difficult to exclude acute gastritis, meningitis, appendicitis, and intussusception. The treatment consists in the exclusion of all food except barley water and broths. Morphine may be necessary in some cases, but rectal infusions of normal saline solution are probably more useful. Some authors strongly recommend large doses of alkalies. Langmead reports two cases of recurrent vomiting, one of which ended fatally. He mentions most of the points brought out by Shaw and Tribe. In addition he states that the vomiting is very frequent—often every quarter of an hour for twelve hours. Free hydrochloric acid may or may not be present in the vomitus. The usual frequency of the attacks is three or four times a year. The duration varies from three hours to seven weeks. They are not traceable to any errors in diet. The excessive thirst is due to the loss of fluid. The state of some of the worst of these cases is very similar to that of a fatal case of diabetes. Respiratory difficulty of the "air hunger" type occurs, drowsiness deepens into coma, the breath reeks with acetone, and the urine (while sugar is absent) contains acetone, diacetic acid, and β -oxybutyric acid. Anorexia occurs in spite of the great thirst. The prognosis is, as a rule, favorable. Authorities agree on only one point in the ætiology—namely, the influence of a hereditary neurotic tendency.

5. Melæna Neonatorum.—Morris and Feldman report a case of melæna neonatorum occurring in a child aged one day. The illness began with severe vomiting of blood, about a tablespoonful being brought up every hour. Blood later appeared in the stools. The child had not been injured during birth, and physical examination showed nothing abnormal. On a treatment of bismuth and calcium chloride, the child recovered. Gastric ulcer has been found to be a cause of melæna neonatorum, and was probably present in this case as the attacks followed immediately after feeding. The cases usually prove fatal.

6. Constipation.—Grey reports the case of a boy aged thirteen years, who for eleven years had had his bowels relieved only at intervals of from three to six weeks. On one occasion two months elapsed between the acts of defæcation. An enormous abdominal tumor was present, which felt like a full term fetus. The treatment

consisted of removal of the fæces by means of enemata of warm olive oil, morphine being given to relieve the pain. In nine days almost thirty pounds were removed—practically a third of the body weight.

7. Ergot and Arsenic in Choreæ.—Rivière uses a mixture of ergot and arsenic in choreæ, with excellent results, one drachm of extract of ergot and three minims of liquor arsenicalis being given at a dose. The unbenefited cases consisted mainly of those violent choreas for which so little beyond isolation can be done.

3. Anæsthetic Mixtures and General Anæsthesia.—Daniell narrates briefly the history of anæsthetic substances and notes the evidences of progress and wider intelligence in their use. He thinks the wise anæsthetist, and the wise surgeon as well no longer limits himself to ether or chloroform or to both, but takes advantage of combinations of one or both of these with other substances, varying them according to the exigencies of the case. He shows that more and more intelligence is being exercised in the choice and administration of anæsthetics, and that the devotion of one's entire time to the study and administration of anæsthetics, which has been the case with a considerable number of men in different countries has resulted in benefit to patients and surgeons alike. There is no ideal single substance or combination and, furthermore, there are very few individuals who are unable, whatever their disease may be, to take some form of anæsthetic with comparative safety. The method of sequences, beginning the anæsthesia with nitrous oxide or some other substance and changing to a suitable combination at the proper moment is highly approved.

Proceedings of Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Meeting of Thursday, January 5, 1905.

The President, Dr. RICHARD C. NORRIS, in the chair.

A Consideration of Fibroid Tumors of the Uterus, Based Upon a Series of Cases Treated Surgically.—Dr. J. CLARENCE WEBSTER, of Chicago, read this paper. He had found in 210 cases of fibromyoma of the uterus the following degeneration:

Calcareous	2 cases.
Cystic	13 cases.
Edematous	6 cases.
Myomatous	4 cases.
Suppurating	10 cases.
Adenocarcinoma of the cervix.....	1 case.
Sarcoma	2 cases.
Hæmorrhagic	3 cases.
Necrosis	11 cases.

Pelvic complications were noted as follows:

Broad ligament development.....	11 cases.
Prolapsus uteri.....	7 cases.
Retroversion of the uterus.....	11 cases.
Hæmatosalpinx	6 cases.
Ovarian cystomata.....	12 cases.
Unilateral salpingo-oophoritis.....	7 cases.
Bilateral salpingo-oophoritis.....	12 cases.
Unilateral oophoritis.....	3 cases.
Bilateral oophoritis.....	20 cases.
Hernia	4 cases.
Appendicitis	26 cases.
Pregnancy	6 cases.

Attention was called to the frequency of diseases of the appendages. In 99 instances there were pathological changes in the tubes and ovaries. The association of malignancy was noted only in two cases. In two there was sarcoma of the corpus uteri involving the fibroid growth; in a third, early adenocarcinoma of the cervix. Cardiovascular symptoms were present in about twenty-five per cent. of the cases.

It was possible that cardiac hypertrophy might sometimes result when the tumor was only of moderate size. A question of considerable interest was that relating to the influence which might be exerted by products of the uterine growth on the heart and other organs through the medium of the circulation. Dr. Webster believed that renal disturbances were more common in association with fibroids than was generally believed. In about thirty per cent. of his cases one or more of the following conditions had been noted: Deficient amount of urine or urea, albumin, casts, and oedema of the feet. In no instance was there evidence of previous organic renal disease, nor did treatment fail to bring about marked improvement prior to operation.

Attention was directed to Noble's views concerning the influence of degenerations and complications of fibroid tumors in influencing morbidity and mortality. The majority of writers had undoubtedly underestimated their influence. The widely held views as to the comparative harmlessness of uterine fibroids, he thought, must be greatly modified. Taking into consideration

the pressure effects, the tumor degenerations, the pelvic and abdominal complications, the changes in the heart, large vessels, kidneys, and liver, the chronic anæmia of hæmorrhagic cases, and other occasional associations, *c. g.*, suppuration, gangrene, peritonitis, phlebitis, embolism, and the influence of pregnancy and labor, the new growth must be considered as seriously increasing morbidity and mortality in women in whom they occurred.

The view held by some that all fibroids of the uterus should be removed surgically unless there was some marked contraindication to operation was not upheld. All large or growing tumors or small ones which caused troublesome or serious symptoms should be treated surgically. In attempting to establish indications for surgical treatment various factors must be considered. Thus, the site of the growth might indicate early removal of a tumor, *c. g.*, a submucous polypoidal fibroid, a cervical growth, one developing extraperitoneally, a subperitoneal tumor tending to fall within the pelvic cavity, etc.

The nature of the tumor might afford an indication, as shown by rapid growth, cystic change, necrobiosis or infection, malignancy, or association with pregnancy.

The size and number of the tumors, within a somewhat ill defined limit, were considered by many authorities as secondary to the other factors in determining surgical interference. One pedunculated subserous tumor, by falling below the pelvic brim, might cause serious pressure symptoms which might never be found with multiple sessile growths. Fibroids should never be allowed to reach such a large size as to become palpable abdominal swellings. The nature of the associated complications might often afford the indication for surgical measures, and it was due to his special study of these complications that Noble had so strongly advised early operation in fibroid disease of the uterus.

In regard to the choice of surgical procedure, ligation of the uterine arteries had scarcely any place in treatment. Removal of the uterine appendages should only be carried out in the rare cases in which other procedures were inadvisable on account of the patient's general condition, or when the relationships of the tumor made removal impossible.

Myomectomy had been less practised than it should have been in recent years, owing to the brilliant results obtained in the reduction of the death rate following total extirpation and supravaginal amputation of the uterus. The conservative procedure had been carried out by the author 48 times in the 210 cases. He thought that more attention should be given to this operation by gynecologists. Supravaginal amputation had been practised in preference to total extirpation as a routine operation, because it might usually be performed in a somewhat shorter time. There was less hæmorrhage, the anatomical relationships of the pelvic floor were better preserved, and there was less risk of wounding the ureters. Owing to recent studies of the complications of fibroids, a serious objection had been raised to the

performance of this operation, namely, the occasional association of fibromyoma and malignant disease. From this standpoint it must be concluded that total extirpation of the uterus was the most scientific procedure.

Dr. ELLICE McDONALD, of Albany, considered the subject of fibroids to be still a very open question and one that was attracting great attention, not only in this country, but in other countries, particularly now in Germany as shown by the recent papers of Winter and Martin. A certain percentage of fibroids were prone to degenerate into sarcoma. He did not believe it entirely settled whether a fibroid might degenerate directly into a sarcoma or whether the sarcoma was grafted on to the fibroid. Since the paper of Whitridge Williams, of Baltimore, published in the *American Journal of Obstetrics* some years ago, the greater number of gynecologists and pathologists had been turning to the idea of a fibroid degenerating directly into a sarcoma. This he considered of great importance, not only to the gynecologist and pathologist, but to the embryologist. The embryologist, he was sure, would finally accept the idea, though it was contrary to all his theories. While carcinoma of the cervix was not more common in fibroid than in the ordinary run of cases, it did seem to Dr. McDonald that adenocarcinoma of the fundus was a little more common in diseased conditions of the fundus or with multiple fibroids.

Tubal complications he considers among the most important in regard to fibroids, because upon the presence or absence of these complications must depend the choice of operation. If it was true that the ovaries were diseased in a great number of these cases, if cystic degeneration of the ovary was more common in fibroid disease of the uterus than in other tumors, it was a question whether the ovaries should be left with cystic disease uneradicated.

One of the most important studies was for some one to give some true idea of the conditions of the surgical menopause. If this was as severe as was taught, if the condition passed off or lasted for a term of years, he asked whether patients should be subjected to this long convalescence; and this question, he said, was not yet satisfactorily worked out. Winter had made a few scattered observations, but no definite study of the condition. In regard to the question of cardiovascular disease, in his fourteen post mortems his findings corresponded with Dr. Webster's, but in three cases there was cardiovascular disease associated with fibroid disease of the uterus—in one case aortic valvular disease, in one brown atrophy of the heart, and in another mitral disease.

The question of the predisposition of the various races was to him interesting, and he thought it should form the basis of all studies of fibroids, because before the study of the mortality and morbidity was undertaken there should be some knowledge of the percentage of occurrence. In his paper read before the Obstetrical Society last winter, he had found from post mortem records, mainly in women of Dutch extraction, that one

woman in every seven in the upper part of the State of New York had a fibroid. The well known predisposition of the negro race to fibroids was borne out by experience. In his service at the lying-in hospital in the city of New York for the last six months, in 2,570 cases, fibroids were found thirteen times, a percentage of less than one half of one per cent. This might be taken as a fairly good estimate of the status of fibroids in women on the east side of New York. In three of these thirteen cases there was post partum hemorrhage. The fibroids were all of the interstitial variety; in two cases the uterus contracted well, but in one case there was alarming hemorrhage. In three cases manual extraction of the membranes was necessary, with immediate packing. In three cases there was malposition of the uterus, two of which were curetted. In five cases there were some pathological lesions of the placenta. In all cases in which there was some alteration in the placenta it was adherent to the fibroid. There was a large area of necrosis which seemed in one case to be a calcareous degeneration of the placenta, but in consideration of the frequency with which this occurred, he thought the fibroid had nothing to do with it. Of the thirteen cases of fibroids, only one came to Cæsarean section. He noted that in obstetrical cases there was this tendency to post partum hemorrhage in all fibroids situated in the uterine wall. He cited one case of pedunculated fibroid in which abortion occurred at three months. Root said that there was abortion in twenty-one per cent. of all fibroids, but Root had not eliminated the cases of gonorrhoeal infection. In the recent paper of Winter there was considered the question of mortality from the standpoint of the various operations. In hysterectomy by the vagina his mortality is $2\frac{1}{2}$ per cent.; in abdominal operation, 4.6 per cent.; in the conservative operation, 5 per cent, and in the conservative abdominal operation, 9 per cent. This bore out Dr. McDonald's views and what Clark and Cullen had laid particular stress upon recently in regard to the danger of doing myomectomy in the presence of disease of the tubes or kidneys. He thought one must look, not only on direct disease of the tubes when pus was present, but on disease of the tubes of any sort as being potential sites of infection. He stated that Miller, of Washington, found streptococci in adhesions ten years after an operation. While Dr. McDonald did not say that there was infection from adhesions in every case, he regarded them as potential sites.

Dr. REUBEN PETERSON, of Ann Arbor, thought it particularly fitting that such a paper should be read before the Obstetrical Society, where the pioneer work along these lines in this country had been done by Dr. Noble, who began at the right end of the problem in giving statistics. In the same way Dr. Webster, by careful tabulation, was able to tell, out of two hundred odd cases, how many of various conditions are present. In approximately eighty recent cases Dr. Peterson's proportion of malignancy was greater than that of Dr. Webster. There were two cases of sarcoma and one of adenocarcinoma. This finding, he be-

lieved, was due to the microscopical examination of every bit of tissue. He cited the following case in which malignancy had been overlooked from lack of such examination: Ten years ago he removed as much as he could of a large fibroid of the uterus. It was supposed to be a common fibroid and reached above the umbilicus. About ten years later the patient returned with a large cystic growth in the right hypochondriac region and the pelvis filled with a large mass, evidently malignant. Concluding that there was a cystic kidney present, he removed it, and it was as large as an adult head. It was found that the supposed fibroid which had failed of removal from the right broad ligament ten years before had been pressing upon the ureter and caused the condition mentioned. Microscopical examination showed the growth to be a slowly growing fibrosarcoma.

Dr. Peterson believed that the patient should be told of the risk of myomectomy compared with total or supravaginal hysterectomy. Dr. McDonald's figures showed a greater risk even than he had supposed. Dr. Peterson's proportion of cases of degeneration of fibroids was not so great as that shown by Dr. Webster and Dr. Noble. From the fact that degenerations did occur, that there were malignancy and cardiac change, he was more inclined than formerly to advise an operation.

Dr. E. E. MONTGOMERY, in considering the question of malignancy, thought it obvious that the mere presence of a fibroid growth, from the increased amount of congestion and irritation, would of itself tend toward the development of malignant disease. In view of the frequency with which fibroid growths occurred, it did not seem to him that the proportion of malignant infection was sufficiently great to assume that the growth was an essential feature in its development. The contraction which took place in fibroid tissue led to atrophy and arrest of its circulation, tending to the development of oedema. This oedema occurred, not only in cases in which strangulation had taken place as the result of the twisting of the pedicle of a subserous fibroid, but also in growths in which there was a tendency to degeneration of the arteries, shown in associated ovarian hæmatoma. He was inclined to think that the disease of the heart and other organs was more frequently found in cases in which the fibroid was of the submucous or interstitial form, where the tendency to hæmorrhage was marked. It was readily appreciated that a fibroid occupying its position in the pelvis and attaining to any size must affect the kidneys by pressure upon the ureters.

Dr. Montgomery agreed with the author that it was difficult to fix a rule for the time of operation. The mere presence of a fibroid growth of the subperitoneal variety he did not consider an indication for operation, but increase of the size of the growth, disturbance of circulation, and degenerative changes warranted an operation. He did not approve of the ligation of the arteries for the control of the growth of the tumor. While he had performed this operation, he had never regarded it favorably from a theoretical standpoint. With the cutting off of the blood supply

sufficiently to limit the growth there was danger of arrest of circulation with resultant necrotic change in the tumor.

The operation of myomectomy appealed to him in women under thirty, in whom it seemed undesirable to bring about the cessation of the sexual function. It was readily understood that a more stormy convalescence from this operation was to be expected from the fact that in the enucleation of a number of single fibroid growths from the uterine wall there was a large amount of tissue of low vitality which was readily infected, and an accumulation of blood in dead spaces from which the patient ran an increased danger. He cited a case in which he did myomectomy for removal of a tumor in a woman thirty years of age. She had a prolonged convalescence, elevation of temperature, and discharge of material through the uterus. Through the induration of the abdominal wall he made an incision by which necrotic tissue discharged. Though convalescence was progressing favorably, the patient encountered serious danger in the effort to save the uterus.

In performing hysterectomy, Dr. Montgomery had for the last four years preferred panhysterectomy to the supravaginal operation, because in an occasional case cancer involved the cervix, and in some cases there had been injury to the cervix. In addition, he believed there was a better drainage, with less likelihood of elevation of temperature, and the convalescence of the patient was more satisfactory after the complete operation.

(To be concluded.)

Book Notices.

The Influence of Growth on Congenital and Acquired Deformities. By ADONIRAM BROWN JUDSON, A. M., M. D., Orthopaedic Surgeon the Out Patient Department, New York Hospital, 1878-1903, etc. New York: William Wood & Co., 1905. Pp. x-276.

Every orthopaedist might study this little book to advantage, and no beginner in orthopaedic surgery can afford to forego the gain that would come to him as a result of studying it. Moreover, parents, teachers and all others who are charged with the care of children may be enabled by it to rescue many a child from serious deformity. It is written in a remarkably clear style, and it sets forth the mature views of a practitioner of great experience.

Atlas and Epitome of General Pathological Histology. By Docent Dr. HERMANN DÜRCHE of the Pathological Institute, Munich. Authorized translation from the German. Edited by LUDVIG HEKTOEN, M. D., Professor of Pathology in Rush Medical College, Chicago. With 176 Colored Illustrations and 36 Figures in Black and Colors. Philadelphia: W. B. Saunders & Co., 1904. Pp. 371. (Cloth, \$5.00.)

It certainly seems a misfortune that the beautiful colored plates and the numerous cuts which accompany this new volume of the Hand Atlases should be forever condemned to be united with a text so

incomplete as this one is on general pathological histology. Not that the text as it stands does not rise far above the standard of the average quiz compend, both in literary form and subject matter. The translation is in general excellent and smooth, the annotations of the editor are well chosen, the selection of the scanty material which accompanies the plates has been well done within the limits given, but the reviewer cannot but feel that a fuller presentation of the difficult topics included under the heading of general pathology should some day be prepared by the author, an able pathologist, well known in his native land as a teacher and investigator.

The Anatomy of the Brain. A Manual for Students and Practitioners of Medicine. The Brain of the Sheep (Ovis aries). By J. F. BURKHOLDER, M. D., Professor of Anatomy in the Illinois Medical College, etc. With an Introduction by Professor HENRY H. DONALDSON, of the Neurological Laboratory of the University of Chicago. With 36 Full Page Plates (5 of them Colored) from Original Drawings by the Author. Chicago: G. P. Engelhard & Co., 1904. Pp. 174. (\$2.00.)

The purpose of this little book is to place in the hands of medical students a laboratory manual describing briefly and succinctly and illustrating by many well executed plates the microscopical anatomy of the brains of the sheep. The brain of this animal is chosen for the purpose because it is of fair size and easily procured at small expense. The book will find a limited field among those medical colleges where the dissection material is not sufficiently abundant for laboratory study of the human brain, but practically an unlimited field in all high schools and literary and scientific colleges where students are taking courses preparatory to entering a medical college. Such preparatory training in dissection and study would be of great practical value to the prospective medical student.

A slight error is noted in naming plates viii and ix. The titles have been exchanged.

Miscellany.

The Fango Treatment.—The establishment of an institution for this treatment in New York renders interesting the following extracts from an article on the subject by Dr. R. Scot Skirving in *Indian Public Health*, for January, 1905:

Fango treatment is the term used in many parts of Europe for the medical application of mud to the affected parts of the body. In Italian the word "fango" means mud, and the variety used is of a specially adhesive, glutinous type. The mud used is of two main varieties: (1) True fango chiefly found in Italy, where its use has been known for ages; (2) and the peaty soils used in central Europe in the Moorbad of German and Austrian health resorts.

The fango of North Italy—of such places as Battaglia or Acqui—is described as a vegetomineral substance, a large portion of which is no doubt of volcanic origin. Its composition is com-

plex and varied. It contains some 35 per cent. of moisture, and among the many inorganic substances the following: the oxides of iron and aluminum, the carbonates of calcium and magnesium, and the sulphide of calcium. Potassium, sodium, barium, and lithium are also represented. Sulphur and a bituminous material of organic origin do not even complete the varied components of the extremely heavy mud. In the Acqui fango there is a relatively high percentage of iron. The Moorbad of places such as Franzenbad is composed of peat. This substance contains a considerable amount of formic acid, as indeed does the peaty soil of various places in the British Islands—a fact well known in connection with lead poisoning by water obtained from a peaty catchment area.

Fango treatment is by no means strictly confined to the districts in which the mud is obtained. On the contrary, in many other places, the treatment is carried out with mud obtained from Italy, and artificially heated in suitable contrived appliances. For instance, at Bex-les-Bains, in the Rhone Valley, the mud used is imported there from Battaglia. In these various places where the mud treatment is practiced various other remedial measures are likewise carried out, such as saline and sulphur baths, douching, Nauheim baths, massage, and electricity. It is especially, however, in places such as Acqui, Battaglia, Dax, and Franzenbad, that the mud treatment is the special feature. In some places the patients sit bodily in the natural mud, but in most of them the hot mud is applied topically to the affected parts in a room suitably warmed and arranged. The application is essentially that of a gigantic poultice—a poultice which, like all poultices, bleeds congested areas, deeply seated, into more superficially placed vascular expansions, and by this temporary depletion and the subsequent reactionary filling, stimulates a healthier tissue change, and thus is favored that removal of inflammatory products which in not a few cases is happily witnessed. If this is the mode of action, one can readily understand why the most benefits are observed in fairly recent cases. Now what are the conditions likely to receive good from fango treatment? Rheumatism in all its forms, gout, rheumatoid arthritis, neuritis, especially sciatica, whether due to nerve inflammation or not; neurasthenia and hysteria; habitual constipation; all kinds of local arthritis, traumatic or otherwise; appendicitis, especially if an indolent phlegmon persists in the iliac region; and, lastly, in pelvic and uterine inflammations. Recent cases of arthritis due to rheumatism, gout, or traumatism very frequently receive marked relief or cure. In Acqui, where the Italian Government have a large establishment for soldiers with injuries and rheumatic affections, the benefits are indisputable. Cases of neuritis of short duration, and especially sciatica, sometimes get well with startling rapidity, combined, of course, with rest. It seems certain also that women with non-suppurative inflammatory troubles in the pelvis or in connection with the uterus and ovaries do likewise receive great benefit, loss of pain and disappearance of exudates being often reported.

The mode of application varies in different places, and with the parts of the body affected. Generally speaking the patient lies on a bed or couch with a rubber cloth and linen sheet spread under him. Mud, either naturally hot or artificially heated (47° C. to 50° C.), is thickly and quickly applied over the affected area. The sheeting is then deftly made to enclose the whole of the limb or body, as the case may be, and usually further coverings are applied if a profuse general diaphoresis is desired. In this poultice pack the patient remains from twenty to forty minutes as ordered, after which time he enters either a simple or sulphurated warm bath, and is washed clean of the fango. He then at once goes to his bed and remains there from one to two hours till his skin is dry and the superficial vessels have returned to their normal calibre. This process is repeated daily for three, four, or five days in succession, and then a day off is allowed, when the sequence is again repeated. From 15 to 21 applications constitute a cure. It is right to say that at first pains in the affected parts are often aggravated; the treatment is said to be "waking up the disease," and further that the benefits to be expected are often not observed "till after the patient has left the place of cure." Massage and electricity form frequent adjuncts to the cure. Little or no medicine is ordered, and there seems less insistence on a rigid regimen than used to obtain some years ago. At Aix in Savoy, strawberries and tomatoes used to be strongly forbidden to rheumatics; now, from certain recent observations on the composition of tomatoes, I find medical men no longer forbid the latter vegetable.

The Treatment of the Muscular Hæmic, and Mechanical Factors in Heart Disease.—Morison, in the *Edinburgh Medical Journal*, for November, 1904, in referring to the distribution of the blood recalls the fact that during the period of physiological activity all the organs of the body are congested. But the organs contain a relatively small portion of the total quantity of blood in the body. The muscles on the other hand form the greatest portion of the body, for they are especially required in all the efforts of the body to obtain its subsistence. To the muscles, consequently, the greatest portion of the volume of blood comes, and from them the blood and lymph go.

Muscular exercise dilates the peripheral vessels and increases the energy of the heart.

In heart disease mechanical treatment has often been found very efficient, though it is not equal to the active movements of the body itself when these are advisable.

The treatment of the hæmic factor in heart disease concerns the quality, quantity, and distribution of the blood.

The quality may be defective in elaboration in oxygenation, or by contamination with infective agents and processes.

The first of these difficulties is to be overcome, if possible, by rest, simple fare, and suitable hæmatinies, the second by deep inspirations of uncontaminated air or of pure oxygen, the third

by antitoxines, bactericidal remedies, and by various stimulating, soothing, and supporting means.

The quantity of blood can seldom be directly diminished by blood letting, though there are occasional cases in which venesection, leeching, or cupping may be indicated, but it is frequently desirable to divert the excess of blood from one part to another by diet, cathartics, nitrites, etc.

The mechanical factor in heart disease refers to the lesion of one or more of the valves or to any form of obstacle in the pericardium. Digitalis helps the heart chambers to contract, but its action is on the heart muscle rather than on the valves; therefore in obstructive lesions of the valves (mitral and tricuspid) or when the resting places of the projected column of blood (aortic and pulmonary valves) are imperfect digitalis is not indicated, but rather belladonna, strychnine, and the nitrites.

On Tactile Sensation.—Horsley, in the *Practitioner*, for November, 1904, contributes an important paper on the subject. He refers to the ancient character of investigations upon the subject of sensation, and to the valuable pioneer work which was done by Galen. The mode of transmission of sensory impulses to the cortex of the brain is still a matter of controversy. The sensory side of nerve physiology must be particularly investigated with reference to the determination of diseases of the cortex, for eight tenths of the hemisphere are concerned with sensation.

Physiologists and neurologists are divided into two camps, in one of which it is believed that the sensory channels terminate in the centres of the optic thalamus, and that new channels start from the optic thalamus to the cortex, while in the other it is believed that the fibres of the fillet go straight through the optic thalamus to the cortex.

Beginning with the peripheral nerves the author asserts that if a fibre of such a nerve is interrupted in any part of its course, it will cause complete loss of tactile sensation in the part of the skin from which it originally started. In his opinion there is no overlapping of the anæsthetic area, the anæsthesia shading off gradually, but on the contrary, the anæsthetic area is divided from the area of sensation by a sharp line.

He next refers to the spinal cord. While the posterior columns are the media for the transmission of sensory impulses the lateral columns also contain channels which go to the brain. When the spinal cord is cut across the loss of sensation is absolute; if only certain segments are injured we shall have lines of anæsthesia which are distinct, and do not overlap, corresponding with the distribution of the injured nerves. In other words, we may have total cord anæsthesia, and root anæsthesia.

Horsley then proceeds to the termini of the sensory channels. The fillet is shown to be in the direct line of the path of sensory impulses and the conclusion is affirmed that the fibres of the fillet coming from the posterior column nuclei simply terminate in the thalamus and that from the thalamus a separate set of fibres goes to the cortex cerebri. In the cortex there is a division

into the motor and sensory part, the former including the convolutions near the fissure of Rolando, and the latter the middle aspect of the hemisphere. But the Rolandic area also receives sensory fibres and hence when diseased may give rise to sensory phenomena. In other words, in every destruction of the motor region of the cortex producing localized paralysis there will also be localized paralysis of sensation and touch, or incoordination. The anaesthesia will be in proportion to the amount of cortex destroyed.

Tactile impressions are therefore located in the Rolandic area, not only impressions of slight tactile sensation in the skin, but the ability to localize exactly the point which may have been touched.

It is therefore possible to differentiate the different kinds of anaesthesia according as the lesion resides in a peripheral nerve, the spinal cord, the part immediately above the spinal cord, or the cortex cerebri.

The Cause and Prevention of Appendicitis.—The *Lancet*, for February 11th, says: Under this heading there appears in the *Nineteenth Century* for January an article which professes to have solved the problem of the aetiology of appendicitis. The author of this communication strongly denounces the use of "Hungarian waters, aperient salts, and liver pills." He then remarks: "It is natural to ask what have aperient waters and salts to do with appendicitis? To that a very true answer is that the action of saline purgatives is to cause a flow of water through the intestinal canal. This passes off quickly, but alas! it leaves the solid portions to accumulate in the caecum at the right side, near the appendix, where the small intestine ends and the large one commences. The solid portions left in the colon become more and more putrid, cause obstruction, and infect the appendix." The meaning of the above sentence is somewhat ambiguous, but we conclude that it is intended to convey the idea that those individuals who habitually take laxatives to insure an action of the bowels are liable to faecal collections in the caecum which produce inflammation of the mucous membrane of the bowel and so cause appendicitis. We venture to express an emphatic opinion that there is no basis for this statement either on pathological or clinical grounds. Any practitioner who has had experience in the post mortem room knows that the contents of the small intestine are liquid, and it is not until the colon is reached that the faecal matters become solid. It is most unusual to find solid faecal accumulations in the caecum; yet this condition is distinctly implied in the remarks which we have quoted above. Further, in post mortem examinations of those who have died from appendicitis, although small concretions may be found in the appendix, no large mass is found in the colon, as would be the case if the aetiology which we are considering were the correct one. Such a causation of appendicitis is also contradicted by clinical experience. The age at which appendicitis usually occurs (*System of Medicine*, by Professor Clifford Allbutt, Vol. iii, p. 806) is from ten to twenty years, which is not the period of life at which such purgatives are

generally habitually taken. Again, constipation is more frequent among women than among men, and the former are more addicted to the habitual use of purgatives, yet appendicitis is nearly four times as common in men as it is by women. It is certainly desirable to overcome constipation by natural means, notably by diet, if possible. But there are numerous cases in which artificial stimulus to the intestines is absolutely necessary and in such circumstances aperient waters and salts are most valuable remedies.

Treatment of Inoperable Cancer of the Breast by Ovarian Castration.—Reynès, in the *Revue de chirurgie*, for November 10, 1904, presented to the French congress of surgery a woman from whom he had removed the ovaries eighteen months previously for inoperable cancer of both breasts. She was 32 years of age, regular in her menses, a nullipara, and the disease which had been proved to be malignant by microscopical examination had rapidly ameliorated after the operation, the ulceration had healed, and the enlarged glands had diminished in size and then disappeared. In a second inoperable tumor of the left breast the ovaries were also removed, but there was no influence upon the cancerous disease, and the patient died in six months.

In the first case the ovaries were healthy, menstruation was regular, and no pregnancy had ever occurred. In the second case the patient's age was 38 years, she had nursed four children from 12 to 14 months, had not menstruated for almost a year before her operation, though her ovaries appeared to be healthy when removed. She nursed her last child from both breasts for two months. The left one then became diseased and the nursing was continued from the other four months longer. The progress of the disease was rapid and castration apparently had no influence upon it.

The condition of the ovaries, as well as that of the mammae, with reference to their functional integrity, must be regarded as of paramount importance in considering the results which are to be hoped for or expected from castration.

In another case of bilateral and inoperable cancer of both breasts in a woman, 41 years of age, the author declined to remove the ovaries inasmuch as the patient no longer menstruated and her genital organs were more or less atrophied. Further experience must clear up the obscurity of this question, but it cannot be denied that there are great possibilities connected with it.

Decapsulation and Fixation of the Kidneys.—Ceccherelli, in the *Revue de chirurgie*, for November 10, 1904, declares that decapsulation of the kidney is a very benign operation, and that a fatal case has never occurred in his practice.

For the first few days after such an operation the urine is concentrated, its density and its cryoscopic point are elevated, and it contains much urea and much solid material.

The kidney being composed of two distinct parts, with different functions, the glomerular portion serving for the secretion of the urine, while the tubular portion serves for the elimination of the solid matter, it is logical to suppose that when

the compression of the fibrous capsule is removed a vascular dilatation will result for a few days, with slowing of the rate of the current. The blood flowing slowly across the kidneys and into the circumtubular vessels, it follows that the urine becomes more concentrated. This hypothesis has been confirmed by Cordera and others who found in their experiments upon animals that decapsulation caused increase in the quantity of urine and congestion of the kidney for a few days. After the first week there was in several cases a marked increase beyond the normal daily average. This shows that the newly formed cortical blood channels found by the writer and other investigators, and by Edebohls himself, at three autopsies which he was able to make, favor diuresis by increasing the irrigation of the cortical substance which received the blood from the ramifications of the renal artery and from the newly formed vessels. When the capsule is reformed the vessels are again subjected to physiological pressure and the blood again flows at its normal rate.

In one of the writer's cases the blood had very little molecular concentration, as observed after cryoscopy. Before decapsulation it had been 0.65 and seven days afterward it had diminished to 0.59. Other cases also gave evidence of deparative renal activity after decapsulation. Similar modifications have been observed both in healthy kidneys and those which were the seat of microbic inflammation.

The author believes that decapsulation should be advised when there is acute functional insufficiency of the organ, the parenchyma being healthy, and that the result will be the prompt deparation of the blood. Decapsulation and drainage should be employed instead of nephrotomy in hemorrhagic nephritis of microbic origin in which the lesions are in the cortex. In cases of prolapsus of the kidneys we are dealing with diseased organs, the circulation being abnormal. If assistance is not rendered a true nephritis will result.

Tuffier observed in 1889 that decapsulation resulted in firm fixation of the kidney to the surrounding tissues, and the author states that he has practised the operation since 1894.

The passage of horse hair sutures through the side of the kidney, and the removal of a sufficient portion of the fatty capsule, show that decapsulation adds an element of success to nephropexy. The modifications in the renal circulation which follow this operation seem to prove that the physiological function of the organ becomes more active and this accords with that which has been observed in the treatment of chronic nephritis by decapsulation.

Official News.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the period from February 26 to March 3, 1905:

Smallpox—United States.

Places.	Date.	Cases.	Deaths.
Florida—Jacksonville	Feb. 1-25	15	2
Illinois—Chicago	Feb. 18-25	38	
Illinois—Danville	Feb. 18-25	4	
Illinois—Galesburg	Feb. 18-25	1	
Kentucky—Louisville	Feb. 16-23	3	
Louisiana—New Orleans	Feb. 18-25	14	1
Massachusetts—Boston	Feb. 18-25	1	
Michigan—At 62 places	Feb. 4-11	Present.	
Missouri—St. Louis	Feb. 18-25	38	5
Nebraska—Omaha	Feb. 18-25	1	
New York—New York	Feb. 18-25	5	1
Pennsylvania—Johnstown	Feb. 18-25	1	
South Carolina—Greenville	Feb. 11-25	5	2
Tennessee—Memphis	Feb. 18-25	20	2
Tennessee—Nashville	Feb. 18-25	2	

Five cases imported.

Smallpox—Foreign.

Argentina—Buenos Ayres	Jan. 1-29	102	25
Brazil—Niteroy	Jan. 1-31	44	
Brazil—Para	Jan. 28-Feb. 11	4	
Brazil—Pernambuco	Jan. 1-15	131	
China—Shanghai	Jan. 7-21	21 foreign- ers, 98 deaths, natives.	
Ecuador—Cota	Feb. 9	Present.	
Ecuador—Columbe	Feb. 9	Present.	
Ecuador—Guamote	Feb. 9	Present.	
Ecuador—Guayaquil	Jan. 31-Feb. 7	23	1
France—Paris	Feb. 1-11	7	1
Great Britain—Hull	Jan. 28-Feb. 4	7	
Great Britain—Leeds	Feb. 4-11	12	
Great Britain—London	Feb. 4-11	6	
Great Britain—Newcastle-on-Tyne	Feb. 4-11	6	
Great Britain—South Shields	Feb. 4-11	2	
Great Britain—West Hartlepool	Feb. 4-11	3	
India—Bombay	Jan. 21-28	109	2
India—Calcutta	Jan. 21-28	1	
India—Karachi	Jan. 22-29	1	
India—Madras	Jan. 21-27	5	
Italy—Catania	Jan. 28-Feb. 9	43	4
Italy—Palermo	Jan. 28-Feb. 11	6	1
Norway—Christiania	Jan. 28-Feb. 11	5	1
Russia—Moscow	Jan. 28-Feb. 4	5	1
Russia—Odessa	Feb. 4-11	2	1
Straits Settlements—Singapore	Jan. 7-14	2	1
Switzerland—Geneva	Jan. 21-Feb. 4	2	
Turkey—Constantinople	Jan. 30-Feb. 6	6	
West Indies—Grenada	Jan. 26-Feb. 9	8	

Yellow Fever.

Brazil—Manaos	Jan. 25-Feb. 8	2	
Brazil—Para	Jan. 28-Feb. 11	2	
Ecuador—Guayaquil	Jan. 31-Feb. 7	2	
Mexico—Coatzacoalcas	Feb. 12-18	1	
Panama—Panama	Feb. 1-14	27	7

Cholera.

India—Calcutta	Jan. 21-28	103	
Russia	Jan. 16-23	6	4
Turkey in Asia—Van	Jan. 9-24	59	20
Turkey in Asia—Van	To Jan. 24	1,200 cases, 500 deaths, estimated.	

Plague.

Africa (Portuguese)—Lorenco	Jan. 17	5 (Suspect)	
Marquez	Jan. 17	9	8
Africa (British)—Port Flor.	Jan. 5-12	154	128
ence	Jan. 5-12	154	128
Arabia—Aden	Jan. 21-28	154	128
Week ended Jan. 21, 113 cases, corrected by Aden plague authority.			

Argentina—Buenos Ayres	Jan. 28	9 (Suspect)	
Brazil—Niteroy	Dec. 1-31	1	
Brazil—Para	Jan. 28-Feb. 11	2	
Egypt—Suez	Jan. 21-28	3	1
India—General	Jan. 14-21	33,083	28,104
India—Bombay	Jan. 24-31	408	
India—Calcutta	Jan. 21-28	58	
India—Karachi	Jan. 21-28	60	53
Straits Settlements—Singapore	Dec. 31-Jan. 14	2	3

Public Health and Marine Hospital Service:

List of the Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending March 1, 1905:

ACHENBACH, JOHN, Pharmacist. Granted leave of absence for four days from February 17, 1905, under provisions of paragraph 210 of the regulations.

BANKS, C. E., Surgeon. Relieved from duty at Chicago, Ill., and directed to proceed to Key West, Fla., and assume command of the service, relieving Passed Assistant Surgeon C. H. Gardner. February 13, 1905.

EERSOLE, R. E., Assistant Surgeon. Granted leave of absence for three days, on account of sickness. March 1, 1905.

GARDNER, C. H., Passed Assistant Surgeon. Upon being relieved from duty at Key West, Fla., by Surgeon C. E. Banks, to proceed to Galveston, Texas, and assume command of the service. February 13, 1905.

GLENNAN, A. H., Assistant Surgeon General. Granted leave of absence for fifteen days from March 6th.

HEISER, V. G., Passed Assistant Surgeon. To report to the Governor General of the Philippine Islands as Health Commissioner in addition to duties as Chief Quarantine Officer of the Islands. February 25, 1905.

RAMUS, CARL, Passed Assistant Surgeon. Detailed as inspector of unserviceable property at Honolulu, T. H. February 27, 1905.

STEVENSON, J. W., Acting Assistant Surgeon. Granted leave of absence for seven days from February 27, 1905, under provisions of paragraph 210 of the regulations.

STONER, G. W., Surgeon. To proceed to Boston, Mass., for special temporary duty. February 23, 1905.

THURSTON, E. J., Pharmacist. Granted leave of absence for ten days from March 10th. February 23, 1905.

Casualty.

Acting Assistant Surgeon ESTEBAN LOPEZ died at Fajardo, Porto Rico, February 4, 1905.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending March 4, 1905:

BARNEY, CHARLES N., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Schuyler, N. Y., and ordered to Manila, P. I., for duty in the Division of the Philippines, on the transport to sail from San Francisco, Cal., about March 31, 1905.

CRAIG, CHARLES F., First Lieutenant and Assistant Surgeon. Relieved from duty at the United States General Hospital, Presidio of San Francisco, Cal., and ordered to Manila, P. I., for duty in the Division of the Philippines.

DE LOFFE, SAMUEL M., First Lieutenant and Assistant Surgeon. Ordered to accompany Second Lieutenant Leshier, Second Cavalry, from Fort Assiniboine, Mont., to Government Hospital for Insane, Washington, D. C.

EKWURZEL, GEORGE M., First Lieutenant and Assistant Surgeon. Left West Point, N. Y., on March 2, 1905, with detachment Cavalry to Washington, D. C.

FIELD, PETER C., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Robinson, Neb., and ordered to Manila, P. I., for duty in the Division of the Philippines.

GOSMAN, GEORGE H. R., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Caswell, N. C., and ordered to Manila, P. I., for duty in the Division of the Philippines, on transport to sail from San Francisco, Cal., about March 31, 1905.

GRAY, WILLIAM W., Major and Surgeon. Relieved from duty at Fort McPherson, Ga., and assigned to duty in the Division of the Philippines. Order revoked.

HOWELL, PARK, First Lieutenant and Assistant Surgeon. Relieved from duty at Fort McPherson, Ga., and ordered to Manila, P. I., with Sixteenth Infantry, for duty in Division of the Philippines.

MURTAGH, JOHN A., First Lieutenant and Assistant Surgeon. Relieved from duty on the transport *Thomas* and ordered to Fort Mason, Cal., for duty and as attending surgeon and examiner of recruits, San Francisco, Cal.

SMITH, HERBERT M., First Lieutenant and Assistant Surgeon. Relieved from duty as transport surgeon on the *Sherman* and ordered to the United States General Hospital, Presidio of San Francisco, Cal., for duty.

STRAUB, PAUL F., Captain and Assistant Surgeon. Reports arrival at Fort Myer, Va., with squadron, Ninth Cavalry.

DUDLEY—SLINGLUFF.—In Baltimore, Maryland, on Tuesday, February 21st, Dr. Benjamin William Dudley and Miss Ethel Crossall Slingluff.

KIMBALL—GALLOGLY.—In St. Louis, Missouri, on Tuesday, February 21st, Mr. Charles Frederick Kimball and Dr. Cecilia P. Gallogly.

MCCUTCHEON—PHILLIPS.—In Brooklyn, N. Y., on Monday, February 27th, Dr. William Hawthorn McCutcheon and Mrs. William E. Phillips.

Died.

BEAN.—In Waukegan, Illinois, on Wednesday, February 22nd, Dr. L. C. Bean, in the eighty-fifth year of his age.

BERRY.—In Anita Springs, Kentucky, on Tuesday, February 21st, Dr. James T. Berry, in the sixty-fifth year of his age.

BOON.—In Chetopa, Kansas, on Monday, February 20th, Dr. G. D. Boon.

BULLITT.—In San Antonio, Texas, on Thursday, February 9th, Dr. Cuthbert Bullitt, in the eighty-fourth year of his age.

CLAIBORNE.—In Petersburg, Virginia, on Friday, February 24th, Dr. John Herbert Claiborne, in the seventy-eighth year of his age.

CLARK.—In Colorado Springs, Colorado, on Friday, February 17th, Dr. C. E. Clark, in the forty-eighth year of his age.

CLARK.—In Pontotoc, Mississippi, on Thursday, February 16th, Dr. Malcolm R. Clark.

DOWNER.—In Newberry, Michigan, on Sunday, February 19th, Dr. F. J. Downer, in the sixty-eighth year of his age.

EDSON.—In Windsor, N. Y., on Thursday, February 23rd, Dr. Isaac C. Edson, in the eighty-second year of his age.

EVERHARDT.—In Detroit, Michigan, on Friday, February 17th, Dr. John F. Everhardt, in the seventy-third year of his age.

FRENCH.—In Denver, Colorado, on Thursday, February 23rd, Dr. Charles Parker French, in the eighty-second year of his age.

HALLEY.—In Kansas City, Missouri, on Tuesday, February 21st, Dr. H. J. Halley, in the seventy-fourth year of his age.

HAMMER.—In Baltimore, Maryland, on Thursday, February 24th, Dr. Milton Elmer Hammer, in the fortieth year of his age.

HYSLOP.—In New York, on Friday, February 25th, Dr. George Lederman Hyslop, in the eightieth year of his age.

LANIER.—In Columbus, Mississippi, on Sunday, February 19th, Dr. Henry M. Lanier.

LEWIS.—In Hubbardville, Kentucky, on Monday, February 20th, Dr. James Fielding Lewis, in the seventy-second year of his age.

LINDLEY.—In Minneapolis, Minnesota, on Thursday, February 16th, Dr. Alfred H. Lindley, in the eighty-fourth year of his age.

O'BRIEN.—In Buffalo, N. Y., on Sunday, February 26th, Dr. Edward C. O'Brien, in the sixty-fifth year of his age.

PENSE.—In Battle Creek, Michigan, on Monday, February 20th, Dr. N. W. Pense.

PIRTLE.—In St. Louis, Missouri, on Sunday, February 19th, Dr. James Taylor Pirtle, in the seventieth year of his age.

PRENDERGAST.—In Brooklyn, N. Y., on Wednesday, March 1st, Dr. John J. Prendergast, in the fifty-eighth year of his age.

PRESCOTT.—In Ann Arbor, Michigan, on Saturday, February 25th, Dr. Albert Benjamin Prescott, in the seventy-third year of his age.

ROBINSON.—In East Freetown, Massachusetts, on Thursday, March 2nd, Dr. William G. Robinson, in the fifty-fifth year of his age.

SCOTT.—In Chillicothe, Ohio, on Saturday, February 25th, Dr. David H. Scott, in the seventy-seventh year of his age.

STAFFORD.—In Rochester, N. Y., on Friday, February 24th, Dr. John Stafford, in the one hundredth year of his age.

WALLACE.—In Pittsburgh, Pennsylvania, on Thursday, February 16th, Dr. Thomas Cushing Wallace, Sr., in the sixty-seventh year of his age.

Births, Marriages, and Deaths.

Married.

COIT—QUACKENBOS.—In New York, on Tuesday, February 28th, Mr. Ralph Bolles Coit and Miss Alice P. Quackenbos, daughter of Dr. John D. Quackenbos.

GONOCOCCUS INFECTIONS IN CHILDREN, WITH ESPECIAL REFERENCE TO THEIR PREVALENCE IN INSTITUTIONS AND MEANS OF PREVENTION.*

By L. EMMETT HOLT, M. D.

NEW YORK,

PROFESSOR OF DISEASES OF CHILDREN, COLLEGE OF PHYSICIANS
AND SURGEONS (COLUMBIA UNIVERSITY).

This subject is important to several groups of specialists as well as to the general practitioner. The genitourinary and orthopædic surgeons, the obstetrician, the gynecologist, and the oculist are all alike concerned in the manifestations of this form of infection, quite as well as those whose interest lies in pædiatrics. Gonococcus infections in children are not limited to hospital or institution practice, nor even to the tenements, although they are much more frequently seen under these circumstances; but may be met with even in children living under the best surroundings and often where least suspected and hence very frequently are overlooked.

I would like to substitute for the commonly employed terms gonorrhœal ophthalmia, vaginitis, and arthritis, the terms gonococcus ophthalmia, vaginitis, arthritis, or pyæmia, since the old terms strongly suggest a venereal origin for these infections. This I believe is the opinion generally held by the laity, but it is seldom the case. On account of its association I think therefore there will be a positive advantage in our discussion if the old term is dropped entirely.

Perhaps I cannot better introduce this subject than by giving a brief account of our experience with gonococcus infections in the Babies' Hospital for the past eleven years. A history of the first five years is given for the sake of comparison with what followed.

In 1894 no bacteriological examinations were made. A diagnosis of gonococcus vaginitis was

based upon clinical symptoms and hence only the most marked or severe cases were entered in the histories either as vaginitis or ophthalmia. Only 7 cases of vaginitis were recorded, all of these having been admitted with the disease; 4 cases of ophthalmia were admitted, all in newly born or very young infants. The only treatment of vaginitis at this time consisted in the use of boric acid lotion every time the napkins were changed, if the discharge was at all abundant. Napkins were boiled, but no special pains was taken in the disinfection or isolation of cases and there is no record of a patient having acquired the disease while in the hospital.

In 1895 the procedure was nearly a repetition of that of the previous year. The total number of recorded cases was 15; 6 cases of vaginitis and 7 cases of ophthalmia being admitted, and 2 having acquired vaginitis in the hospital.

In 1896: For the first eight months of this year there was no case of gonococcus infection recorded. This year the clinical laboratory was opened in the hospital and microscopical examinations made of vaginal discharges in many of the cases, establishing the fact that cases of vaginitis such as we had been seeing were due to the gonococcus. The total number of cases for the year was only 9; 4 of vaginitis and 2 of ophthalmia being admitted, while 2 cases of vaginitis and one case of arthritis developed in the hospital. The last was a case of gonococcus arthritis and general pyæmia in a little boy, five months old, admitted for marasmus. This child had many joints affected and died of a meningitis seventeen days after admission. Inasmuch as he had occupied the same ward with three marked cases of vaginitis, in two of which the nature of the infection was determined by bacteriological examination, there seems little doubt that the disease was acquired in this way. At the time, however, this possibility was not thought of, but in the light of experience of later years there now seems to be no doubt that this was a case of direct contagion.

In 1897 an increasing prevalence of the disease

* Read before the Academy of Medicine.

was noted, possibly because now bacteriological examinations were more frequently made and we were more watchful for mild cases. There were 11 cases of vaginitis and 6 cases of ophthalmia admitted; 5 cases of vaginitis and one case of ophthalmia developed in the hospital, the latter being in a patient who had also a gonococcus vaginitis. This incident showed the importance of applying napkins to all children no matter what age.

The year 1898 was much like the preceding years, 5 cases of vaginitis and 12 cases of ophthalmia being admitted; 5 cases of vaginitis developed in the hospital. In spite of this rather large number of ophthalmia cases no accident was noted, except in the case of one nurse, whose eye became infected and the sight permanently impaired in spite of early and energetic treatment.

During 1899 we experienced our first epidemic and realized what a scourge gonococcus vaginitis might become in an institution. In the first five months of this year only 5 cases are recorded; 4 of vaginitis and one of ophthalmia. But in the beginning of June three children were admitted and transferred at once to the country branch before it was discovered that they were suffering from vaginitis. All of them came from the same day nursery. These children proved to be the beginning from which there developed a serious house epidemic which continued during the entire summer. Eight other children who were admitted were found to have the disease, and 15 girls contracted gonococcus vaginitis while in the hospital, these being practically all the inmates of one of the cottages.

The united efforts of the physicians and superintendent in quarantine and disinfection proved ineffectual in checking the spread of the disease. No special care was taken this summer to exclude cases of gonococcus infection from the admission ward in the city, but as soon as cases were discovered after they were sent to the country they were immediately transferred to the infected cottage. The means of prevention employed at this time consisted in separate nurses for infected cases and boiling and disinfection of the napkins. The napkins of the infected cottage were washed separately from the others. Yet in spite of these precautions every girl placed in the infected cottage, which was a dormitory for the larger children, contracted vaginitis. Occasionally a case would break out in one of the other cottages, but immediately was transferred.

The type of disease seen in this epidemic was moderately severe, most of the cases being characterized by a profuse discharge of yellowish

green mucus. Owing to the fact that special precautions were taken not a single child or nurse contracted ophthalmia.

The experience of this summer made a deep impression upon all the physicians and nurses at the hospital. Care was taken that no children should be returned to the city hospital from the country branch. At the end of the season not only napkins, but all bed linen, blankets, and children's underclothing were boiled, then fumigated, and all the wards, closets, etc., were cleaned and submitted to as thorough a fumigation as after scarlet fever.

Greater care and watchfulness were exercised from this time forward regarding the admission of infected children to the wards; a few such, being found to have the disease, were when possible immediately discharged, or at once quarantined, and for the time no more cases of ophthalmia were received. The result of these efforts was that for the rest of the year 1899 and during the whole of the year 1900, a period of sixteen months only, 10 cases of gonococcus infection were recorded, 4 of these being admitted, and 6 having acquired the disease from them.

The year 1901 was almost a repetition of 1899. Very little trouble was experienced in the city hospital with the gonococcus infections during the first five months. There were 11 cases recorded, 6 patients being admitted. Unfortunately one child, a girl of two years of age with gonococcus vaginitis, was sent to the country branch, where on account of her other ailments she was retained for three months, and we innocently received from another hospital in New York two children, both of whom were found to be suffering from gonococcus vaginitis. These three cases proved to be the starting point of another house epidemic, and 22 cases of vaginitis occurred during the four months of summer, 14 developing the disease in the house. The same inability to check the spread of the disease among the children who occupied the infected cottage was experienced as two years previously, so that it became necessary in the middle of the season to stop admitting female children altogether. On reopening the city branch of the hospital in the fall, the disease was quickly brought under control and during the last three months of the year only three children acquired it, although five were found to be suffering from it on admission. When at its height in the summer no amount of napkin disinfection had any effect in checking it, and a general house infection seemed to be the only explanation of the development of these cases.

The record for the year 1901 was: Total 47

cases, 16 cases of vaginitis being received and 22 developing in the wards; 6 cases of ophthalmia admitted and 3 cases acquired. Four children with ophthalmia had also vaginitis, but in three it is interesting to note the ophthalmia appeared before the vaginitis.

In the first five months of 1902 only 3 cases of gonococcus infection were recorded, 2 being admitted with vaginitis and one having acquired the disease. More stringent regulations were now enforced regarding the admission of children, particularly those who were to be transferred to the country. Yet notwithstanding these precautions, 6 children with vaginitis were unintentionally admitted at various times during the summer, 3 of these having been received from other institutions. These were quarantined as soon as they were discovered, but 11 secondary cases occurred.

The development in the wards of 3 cases of multiple gonococcus arthritis was a new phase of the disease, especially as one occurred in a male infant only two and a half months old and another in a female infant of one year, without vaginitis, and none of the children had ophthalmia. All these cases were confirmed by bacteriological examination. They forced us to seek for some other portal of entry for the organism than the eyes or the vaginal mucous membrane. The first case seen occurred in a child three months old, whose symptoms so closely resembled acute articular rheumatism that she was treated with salicylates until suppuration of the joints became so evident that a needle was inserted and pus containing gonococci withdrawn.

In November, 1902, the new building of the Babies' Hospital was opened, and into our paradise the serpent came in the form of a child with a severe gonococcus vaginitis, who was unintentionally readmitted as she had been known as an intractable case during the previous summer. Although no other cases of vaginitis were received, and but one ophthalmia, during the next few weeks with absolutely clean new wards 11 fresh cases developed, including 3 of gonococcus arthritis, all in boys under two and a half months old. In spite of all the precautions taken it seemed almost impossible to check the spread of the infection. For a time female children were refused admission unless suffering from urgent symptoms requiring hospital treatment, and if then received were put in the infected ward and kept there in quarantine. At first we allowed male children to remain in the same ward with cases of vaginitis, until the occurrence of arthritis indicated their susceptibility. Every imaginable mode of spreading the disease was taken

up for consideration and precautions enforced. These will be discussed later.

Our experience of the first six months in the new hospital building emphasizes more forcibly than anything else can do how extremely contagious is this form of infection and how difficult to control. During this period from 5 cases admitted there developed 29 cases of vaginitis and 8 cases of gonococcus arthritis; one case of ophthalmia was admitted, none acquired.

During the following summer, 1903, renewed precautions were taken to prevent the spread to the country branch, but here accidentally infection was introduced by a child admitted from another hospital. The summer cases, while not quite so numerous as were those of the two previous years, were still sufficient to cause us great anxiety. Six cases were admitted and 24 acquired. The same precautions as heretofore were taken and more energetically carried out; however, it was found impossible to prevent their contracting the disease when occupying a cottage where there were cases of gonococcus vaginitis. The city hospital was not closed during this year, and consequently we were never at any time entirely rid of the infection there.

The record for the year was: 10 cases of vaginitis admitted, 55 acquired; 1 case of ophthalmia admitted, 1 acquired; 2 cases of arthritis admitted, 10 acquired. It should, however, be stated concerning these figures that the larger number of vaginitis recorded is in part to be explained by the fact that routine examinations at the house were regularly made and many mild cases discovered which without such examinations would not have been recognized as gonococcus infections. Such were fully 60 per cent. of the vaginitis cases.

In the early part of 1904 there was a continuance of the epidemic of the winter of 1903, but from the first of April until the end of the year the cases admitted were few and any general extension of the infection readily prevented by the adoption of the most rigorous measures with the appearance of the first cases.

A new rule was inaugurated during the summer, viz., admitting no female child without a microscopical examination of the vaginal secretion and refusing infected children unless they were in urgent need of hospital treatment, under which circumstances they were received and placed in quarantine.

The record for the year 1904 was: total number of cases, 52, of which there were 46 cases of vaginitis, but only 16 of these would have been diagnosed as such without a bacteriological examination, the amount of discharge being so

slight that they would easily have been passed over had we relied upon the clinical condition. One case of gonococcus ophthalmia was admitted and 6 cases of gonococcus arthritis developed in the wards.

Such is a brief summary of our struggle to combat this form of infection in the Babies' Hospital during the past eleven years.

The impression having gained a certain currency that this institution has had more vaginitis and other forms of gonococcus infection than other institutions of the city receiving children, I have been at some pains to ascertain what conditions prevailed elsewhere. The conclusion has been that there has not been more vaginitis in the Babies' Hospital than in other institutions for children, but since the adoption of vigorous measures of quarantine and treatment much less than most of them.

In seeking to determine how much vaginitis existed elsewhere I have not depended upon annual reports, for it is seldom even mentioned there. Occasionally physicians, but more frequently head nurses and hospital superintendents have been our informants. These have come to us from almost every large hospital in the city, endeavoring to learn what they could do in their own institutions to eradicate this form of infection from their children's wards, since they found it almost constantly present. Another source of information has been the infected cases which we have received from other institutions, the list of which includes almost every large hospital in New York; we have received also very many more cases from the day nurseries. The matrons and managers of these institutions are I believe seldom aware of the prevalence of such a form of infection and of its very contagious character. Possibly from motives of modesty or fearing publicity cases of vaginitis have been concealed or ignored. Besides the above sources of information, bacteriological examinations have been permitted in three institutions for children by our resident physician, Dr. Dorothy Reed, who with Miss Wheeler, the superintendent of the Babies' Hospital, has worked most indefatigably in the solution of this problem. To them I am indebted for many of the details presented in this paper.

The institutions selected were of different kinds, and it was thought might give some idea of how generally prevalent gonococcus vaginitis is.

I. An institution receiving infants and young children. No isolation is practised; no examination of vaginal discharge on admission. The only treatment employed is douches where the dis-

charges are noticed. The authorities stated that there was no vaginitis in the house.

Smears were made from the vaginal secretions of 100 infants and young children, the cases being taken in order; no selection was made.

Findings.—Twelve children showed a yellow purulent discharge. Pus and gonococci were found in all by microscopical examination. Twenty other cases showed a very slight discharge; the microscope revealed many pus cells, but no gonococci. A considerable proportion of cases like this from our previous experience we have found subsequently show organisms if repeated examinations are made.

II. An institution receiving infants and young children. Smears are reported to be made on the admission of children, and cases are said to be isolated when recognized. The authorities conceded the existence of two cases of vaginitis.

There were 56 children examined. Smears in 6 cases showed gonococcus and vaginal discharge of pus; in 4 it was abundant. In none of these cases was any attempt at isolation made. Numerous pus cells were found in the secretion of 13 other children, but no gonococci were present. They may justly be regarded as suspicious cases. The superintendent of this institution regretted she did not know the time of the intended visit, that the children might have been previously bathed.

III. A home for children from two to ten years old. No microscopical examinations are made; children are quarantined for six weeks before they are received into the general household. Careful inspection is made by an efficient superintendent twice a week for vaginal discharge. She reports that during her residence of seventeen years there has never been an epidemic of vaginitis.

Smears were made from the vaginal secretion of 77 children; 2 positive cases found, i. e., purulent vaginitis with the gonococcus present in the smears. There were 10 suspicious cases, i. e., considerable pus in the discharge, but no specific organisms found.

This was a remarkably clean house and the children showed every evidence of being well cared for.

It will I think be evident from these facts that gonococcus infections, especially vaginitis, are exceedingly frequent in institutions for children, highly contagious, and very difficult to control. I cannot resist the conclusion that they are steadily increasing in New York city. In a single day in the summer of 1904 five children who applied for admission were found to be suffering

from gonococcus vaginitis; this was of course an exceptional experience. Usually in summer several such cases are discovered each week; in the winter there are not generally so many, but there are rarely less than five or six a month among an average of 125 applications.

Of the greatest difficulties in eradicating gonococcus vaginitis from institutions is due to the prolonged duration of the cases and the obstacles in the way of complete cure. Where this infection is known, it is justly regarded as the *bête noire* of institutions for children, the importance of which has only just begun to be appreciated.

CLINICAL MANIFESTATIONS.

The statistics previously presented in the paper relate only to the three principal clinical forms of gonococcus infection which we have observed: vaginitis, ophthalmia, and arthritis. It should be remembered that these observations have been made upon infants and children up to three years of age. Besides these, three cases of meningitis occurred in children suffering from gonococcus arthritis, in no one of which, however, was the gonococcus found in the meninges, one was staphylococcus, one is put down as pneumococcus. As this was several years ago this may possibly be regarded as doubtful; in the third no bacteriological examination of the exudate was made. In two instances abscesses containing the gonococcus elsewhere than in the joints were observed, one in the axilla and one in the wall of the trachea, to which I shall refer in another connection. Only one case of gonococcus urethritis in a male child was seen; this boy, two years old, was admitted with it and a clear history was obtained of infection in his home. There were no instances of endocarditis or pericarditis, of peritonitis or pelvic inflammation, and none of proctitis.

Vaginitis.—There were in all 273 cases of vaginitis observed, 101 of which were admitted with the disease and in 172 cases it was acquired. In well marked cases of gonococcus vaginitis in young children the symptoms are fairly easy of recognition. The discharge is moderately abundant, of a yellow or greenish yellow color, occasionally tinged with blood. An extension of the inflammation to the uterus, tubes, and peritonæum we did not observe, nor was cystitis met with; urethritis also was not common and seldom severe.

In the milder cases in infants the discharge may be so slight as to escape observation except by close inspection. If in such cases careful attention to cleanliness is practised the disease may remain unnoticed for a long time. The detection of such cases we have found to be facilitated by placing

between the labia a fold of gauze upon which the yellow discharge can readily be seen. The hospital nurses are instructed to report such a condition and the microscopical examination almost invariably establishes the fact that with such discharges the gonococcus is present.

The question has often arisen whether these mild cases which remain mild are really cases of gonococcus vaginitis. There can I think be no doubt upon this point, both from the bacteriological examinations and from the clinical course, since some such cases may if neglected grow worse and develop into a typical form of the disease. The infection seems to be due to a less virulent type of organism, or else the local conditions do not favor its growth. At all times in the hospital mild and severe cases have been found associated, exactly as they are seen in other forms of infection. Constitutional symptoms with gonococcus vaginitis even when of a severe form are very few and insignificant; seldom was there a temperature noted over 101°.

A few words may be permitted about the microscopical examination of smears from vaginal secretions. It is well known that the gonococcus is a diplococcus which decolorizes when stained by Gram's method; also that to be diagnostic it must be found within the pus cells. It is characteristic of gonococcus vaginitis that this organism, though existing in large numbers, is usually the only variety present, which fact materially assists in diagnosis. If there are many varieties of bacteria in a vaginal secretion, the case will seldom be one of gonococcus vaginitis. If pus is found and few organisms detected, it is probably a case of gonococcus vaginitis, even though pus may be small in amount; in such cases subsequent examinations usually reveal the gonococcus. It has been the custom in the Babies' Hospital to class as "suspicious" all cases of vaginal discharge in infants in which many leucocytes were present, most such turning out to be genuine cases. In our experience a non-specific purulent vaginitis has been uncommon, such cases forming hardly five per cent. of the vaginitis cases seen in the hospital.

One of the most troublesome features of gonococcus vaginitis is not its severity, but its intractability. Frequently cases that were only moderately severe would continue for six or eight weeks in spite of constant local treatment. One of the greatest difficulties is in the use of proper local measures in these very young patients.

Ophthalmia.—I have nothing to add to what is well known regarding the gonococcus ophthalmia of young infants. Early in the history of the hos-

pital it was customary to admit these cases in small numbers, almost all of them being in newly born children and of a very severe type. We do not now receive these cases, for although hospital treatment is absolutely necessary, they can be best cared for in special hospitals for diseases of the eye. It is gratifying to record the fact that during the eleven years there were only 6 children who contracted gonococcus ophthalmia in the institution, and as 4 of these had also a gonococcus vaginitis they may be considered cases of autoinfection. Only one nurse became infected.

Arthritis.—On account of the acute febrile nature of the joint symptoms accompanying gonococcus infection these cases may perhaps be more exactly characterized as gonococcus pyæmia. Clinically this was the most interesting phase of the gonococcus infection observed in the Babies' Hospital. Dr. R. B. Kimball has already made a report upon 8 of these cases,¹ but a study of the entire series of 26 is interesting, since I believe that nowhere in the literature of gonococcus infections is there a record of so large a group of cases of this kind in a single institution.

It is a striking fact that 19 of these were male children and 7 female. Four of the females suffered also from vaginitis, while in only one of the males was there other clinical evidence of gonococcus infection, this patient having also ophthalmia.

Sixteen of these joint patients were three months old or under, two of them being under one month; one of these was the boy with ophthalmia and the other had also vaginitis. Five cases occurred between the fourth and sixth months, three in the second and two in the third year.

A single joint only was involved in but 5 cases, twice the knee, and once each the ankle, wrist, and metacarpus. Three or more joints were involved in 16 cases, the largest number being 8 joints, viz., both wrists, both ankles, both knees, one shoulder, and one temporomaxillary. In most of the cases four or five joints were affected. The order of frequency in which the joints were involved was as follows:

	Times.
Finger or metacarpal.....	20
Ankle.....	18
Knee.....	17
Wrist.....	12
Toe or metatarsal.....	10
Shoulder.....	9
Elbow.....	5
Temporomaxillary.....	1
Hip.....	1

¹ Medical Record, 1904.

The local symptoms were best seen in the superficial joints, such as ankle, wrist, or knee. There was a rapidly developing articular swelling with early redness, very acute tenderness and, in the cases going on to suppuration, usually fluctuation at the end of a week. There was not much œdema or swelling in the neighborhood of the joints, but all the usual characteristics of an acute pyæmic arthritis were seen. I cannot state accurately the number of joints in which the inflammation terminated in suppuration, but fully one third and I think rather more than this resolved. The pus drawn by a needle or evacuated by incision was more frequently a thin seropus than thick and creamy. The diagnosis of gonococcus infection was determined by bacteriological examination in every case.

The general symptoms were of a pyæmic character. Of the 21 cases in which temperature charts are preserved, the fever reached 103° or over in 15 cases; in 5 it was 104° and in one 105°. The usual range was between 100° and 102° or 103°. The temperature curve was an irregular one, exacerbations in the fever occurring very often as the successive joints became involved. The fever lasted in one case for eight weeks; in nine cases either three or four weeks, in four cases two weeks, and in seven but one week. The other symptoms were wasting, prostration, and exhaustion. Fourteen of the children died and twelve recovered or were discharged and subsequently lost sight of. In many of the cases death was not due to gonococcus pyæmia, but to the condition of general marasmus with which it was often associated.

The pathological process in the joints in so far as we had an opportunity to observe it was an acute inflammation chiefly affecting the synovial membrane, rarely involving the cartilage or other joint structures and no destructive changes were observed. A very considerable number, but not all of those which survived, were followed, so that the ultimate result of the joint inflammation could be obtained, some being seen as late as a year after the attack. There was complete recovery of function in many and slight stiffness in a small number, and marked fibrous ankylosis in only one or two. In none was bony ankylosis seen. In children whose general condition was even fairly good, early incision and washing out usually sufficed for a rapid cure, and in some incision only was practised and the joints were healed inside of a week. Prolonged discharge with the formation of sinuses was not seen.

The difficulty in diagnosis in some of these cases has already been referred to, the first case

seen very closely resembling acute articular rheumatism. The latter disease, however, is so exceedingly rare in an infant under a year that a pyæmic arthritis should always be suspected with such symptoms as those which we have described. A pyæmic arthritis in a young infant I believe is very much more frequently due to the gonococcus than to the streptococcus or any other pyogenic organism.

(To be concluded.)

THE AFTER-TREATMENT OF ABDOMINAL SECTIONS WITH ESERINE SALICYLATE.*

By DANIEL H. CRAIG, M. D.,

BOSTON, MASS.,

SURGEON TO OUT PATIENTS, FREE HOSPITAL FOR WOMEN;

INSTRUCTOR IN GYNÆCOLOGY, BOSTON POLYCLINIC; FELLOW

OF SOUTHERN SURGICAL AND GYNÆCOLOGICAL ASSOCIATION, ETC., ETC.

Having, in two previous papers,¹ gone somewhat explicitly into details as to the mode of origin and the physiological and pathological modus operandi of postoperative intestinal paresis, together with the exact physiological action and therapeutics of eserine salicylate in antagonizing such paresis, I have determined, in order to keep this paper within proper time limits, notwithstanding the generous liberality of your chairman in assigning me no hard and fast time limitation in his invitation to appear before you, to confine my remarks upon this occasion to the actual details of the after-treatment of abdominal sections with eserine salicylate. This is fortunately rendered the more easy by the receipt of numerous letters of inquiry and still more by personal discussion with the members of the Southern Surgical and Gynæcological Association at their recent meeting. It shall be my purpose to elucidate such points as have been ill understood or misunderstood so far as they shall have come to my knowledge. And inasmuch as most if not all of the disappointments of which I have learned have originated in a misapplication of the principles involved, this brings me thus early to the point of urging upon any one who may deem this method of treatment worthy of a trial the close following of the suggested line of procedure, which is the result of many months of careful experimentation, until such time as thorough familiarity may suggest changes or improvements. The advisability of this course is shown by such articles as that by Pankow,² in

which, through an incorrect employment of eserine, his deductions appear worthless. In the first place he used too small doses to get uniform results, and in the second he classified his cases so badly as to demonstrate the fact that his variable results were in no wise dependent upon the failure of eserine as used, or rather misused, by him. The too small doses employed by Pankow were at one time used in my own experiments and nearly led to the abandonment of the entire work. Lastly, he classed the intestinal action following one hundred Alexander-Adams operations with the abdominal sections. Needless to say, if the Alexander-Adams technics was followed no cause for postoperative intestinal paresis existed. Pankow's work was undoubtedly inspired by the work of von Noorden and Oppenheim with eserine, rather than by mine.

While speaking of the dosage permit me to explain that there is and should be no one routine dose, but the amount employed should be adjusted, whenever possible, to the demands of the individual patient. Inquire carefully into the general state of the ordinary bowel activity and in a patient giving a history of normally active bowels, in whom the bowels are always readily influenced by relatively small doses of cathartics, one sixtieth of a grain is usually all sufficient, especially if the bowels are fairly or thoroughly empty at the time of operation. When used in this small dose it may be repeated even in a very short time if it is found that the judgment is at fault and the dose too small.

If, on the other hand, the patient gives a history of chronic constipation, the full therapeutic dose of one thirtieth of a grain should be used, and if it is clearly shown that the constipation is due to atony of the intestinal muscles or if the patient has been persistently dependent for a considerable time upon frequent enemata, a larger dose, one twenty-fourth, or even one twentieth, of a grain should be given.

Lastly, in a third class of cases in which, owing to a lack of time or to a lack of adequate intelligence on the part of the patient, no satisfactory bowel data can be obtained, it is best to give a medium dose of one fortieth of a grain, and repeat at the first indication that the dose has been inadequate.

I thus speak of the repetition of the original dose, but as a matter of fact, since arriving at a thorough understanding of the correct dosage, repetition has been very rarely indicated.

Moreover, eserine salicylate should never be thus used except in conjunction with atropine, be-

* Read by invitation before the New York Academy of Medicine, Section in Obstetrics and Gynæcology.

² *Zentralblatt, f. Gynäk.*, June, 1904.

cause, as shown in my original paper, atropine systematically antagonizes all the undesirable actions of eserine and vice versa, while they unite in stimulating intestinal peristalsis. This latter action of atropine has recently received emphatic confirmation in an elaborate series of experiments by Riedel³ who has thus shown that atropine always stimulates peristalsis whether the dose is the minimum which will produce any effect or one so powerful as to be fatally poisonous.

The eserine should be administered subcutaneously. No advantage has been seen in giving it deeply in the muscles.

The time of its administration is of prime importance. The atropine should always be given, as it is so commonly used by surgeons generally, before the anæsthesia, first, because its action is slower than that of eserine, and, secondly, because when so used it gives great aid to the anæsthetist in doing away with most if not all of the excessive pharyngeal secretion excited by the first inhalations of the ether. I give the atropine in a dose of one one hundredth of a grain by the mouth one hour before anæsthesia when there is time, otherwise one one hundred and fiftieth of a grain subcutaneously immediately before. I do not find that it greatly matters which course is pursued.

The chosen dose of eserine is placed in a hypodermic syringe while the patient is being prepared for the abdominal incision, and is kept warm and ready for instant use. As soon as practicable after the opening of the peritoneal cavity, the entire field of operation is explored, and if no condition is found which offers the slightest possibility of jeopardizing the integrity of the intestinal tunics below the peritonæum, the eserine is ordered to be administered at once. In pelvic surgery it is not uncommon to order the eserine from two to five minutes after the initial incision through the parietal peritonæum.

But just here is where some have misinterpreted me in thinking that I advocate its administration at this point in all cases, which I do not. Others have tried to improve the whole matter by giving the eserine before the operation is begun, but such a practice cannot, in my opinion, be too emphatically condemned, because, while well maintained or quickly restored normal peristalsis is a boon to both surgeon and patient alike in the vast majority of cases, it is none the less true that there is a well defined class of cases, of which instances are unexpectedly encountered, in which absolute intestinal rest is imperatively demanded, making such an early administration of any form of cathartic unjustifiable. When such

examples are encountered in the course of an operation, the eserine should be withheld until such especial indication for intestinal quietude has passed. Such cases are those in which strong or numerous adhesions are encountered, in the liberation of which the intestinal musculature may be so injured as to render rest necessary, in which case the eserine should be withheld until all adhesions have been liberated without inflicting such injury, when it should be given at once. Also in intestinal resections or anastomosis it should be withheld during the process of healing, just as we have heretofore allowed intestinal rest. There is also a third class of cases in which for one reason or another we are forced to terminate an operation, feeling certain that we are leaving more or less septic material within the peritoneal cavity. In all such no form of cathartic or peristaltic stimulant which would interfere with the protective walling off process should be given. In a letter, Wetherill, inclosing a reprint of his paper, arraigns me for giving eserine "in the face of peritoneal sepsis or inflammation." Unless active potential peritoneal sepsis and infection are to be expected after every aseptic opening of the peritoneal cavity, such an employment of eserine has never been advocated by me, and, while Wetherill and I have points upon which we differ, we at least agree that in the presence of active advancing peritoneal infection or inflammation either the source of infection must be thoroughly eradicated or the walling off process must be favored to the utmost. Whether or not eserine should be used after or during a case in which peritoneal infection or inflammation has been a factor, must be left, as it safely may, to the judgment of the surgeon in each case as to whether or not the source of such infection or inflammation has been so thoroughly removed as to render further intestinal rest unnecessary. It is probable that Wetherill's error as to my views arose from my advocacy of eserine in the prevention of adhesions, but I at no time referred to the form of adhesions which nature throws out as a protective barrier about inflammatory foci, but rather to such adhesions as follow abraded peritoneal surfaces in the course of operations which subsequently prove to be at least practically aseptic; in other words, to the same class of adhesions for which careful peritoneal covering of all raw surfaces is practised, for which the omentum has been stitched over the raw surface, and for which the Cargile membrane has been used. Certainly we all agree that this class of adhesions may with safety be eliminated by any means not involving greater danger than the adhesions themselves.

³ *Rousky Vrach.*, June, 1904.

Then, too, the necessity of eserine in every case has been questioned, and here, again, I have been misinterpreted. Stone, in a paper yet to be published, but presented at the recent session of the Southern Surgical and Gynecological Association, cites me as expecting intestinal paresis after each and every abdominal section. Yet such is not and never has been my position. What I do maintain is that it is a fact that the abdomen is never opened without in a greater or less, usually less, degree inhibiting normal peristalsis. The cases in which this inhibition reaches the point of becoming a fatal or even dangerous paresis are exceptional, but they do nevertheless occasionally occur, and when such a case is encountered I know of no condition which so completely demonstrates, both to the surgeon himself and to all concerned with the patient, the surgeon's utter impotence to combat it. Moreover, it is impossible from the most minute study of the literature of the subject, the reports of such fatal cases, or the histories of patients about to be subjected to operation to forecast in the least degree which cases will develop such a paresis. Therefore, when we possess a preventive remedy so absolutely harmless as eserine salicylate, used in conjunction with atropine has proved, we are not only justified in employing it in each suitable case, but it is a question if it is justifiable to omit its use.

Without going into details, which have been elsewhere given, the manner in which eserine prevents intestinal paresis is briefly as follows: The exposure of the visceral peritonæum to the lower temperature, to the drying of evaporation, and above all to manipulation immediately establishes an irritation of the sympathetic nerve terminations in the intestine, which, generating a centripetal nerve impulse immediately, in turn invokes a marked reflex inhibition of all muscular movement, which reflex inhibition is conveyed to the bowel over the fibres of the splanchnics. But in Auerbach's and Meissner's plexuses the intestine has been shown to possess a nervous mechanism which is so powerful as to render it absolutely autonomous when freed absolutely from all central nervous connection. Therefore the moment splanchnic inhibition is instituted the ganglia of Auerbach's and Meissner's plexuses institute a nugatory muscular excitation, and in the overwhelming majority of cases the force in these intrinsic plexuses is so much more than equal to the task of overcoming the splanchnic inhibition that, after a temporary battle, the normal peristalsis is completely restored, which is materially aided by the fact that the splanchnic inhibition apparently ceases promptly upon the restoration

of the visceral peritonæum and intestine to their normal conditions as to temperature and manipulatory irritation. But it is in those cases in which either the splanchnic inhibition is abnormally persistent or the intrinsic resistance is abnormally weak that a serious degree of paresis results and in which eserine is able so to equalize these forces as to prevent serious symptoms.

This form of peristaltic arrest is, therefore, of an entirely different mode of generation from that instituted by nature apparently for the protection of infected or inflamed peritoneal areas. For while it is entirely true that absolute asepsis is probably never achieved, it is also as certainly true, as demonstrated by innumerable cases in which, for one reason or another, the abdomen has been reopened both early and late after abdominal sections in which eserine has not been used, that asepsis has been sufficiently complete to leave no traces of peritonitis behind, and in my cases in which I have used eserine the charts have failed to show any additional labor on the part of the organism in disposing of the minimal quantity of infection introduced. Indeed, on the contrary, thanks, as I believe, to the omission of the depletion of the blood stream by saline catharsis, the charts have been noticeably better, the so called "reaction" temperature, which is probably in reality an index of the work of "resistance" in disposing of the infectious material introduced, has been less both in degree and in duration.

To quote Wetherill once more, he further says: "Nobody maintains that autointoxication from intestinal decomposition and extreme distention of the abdomen from tympanites, aperistalsis, and antiperistalsis, are not dangerous in themselves." He further says, very correctly, that when a choice is forced upon us between treating this condition and that of peritoneal infection and inflammation we must certainly give the latter first consideration. To this I emphatically assent, but in the absence of this latter, at least in any potential degree, are we to neglect the former? Wetherill says yes and I say no.

The last point in his paper which I wish to mention here is the following statement: "Even aperistalsis, or so called reversed peristalsis, is not without its beneficent agency in so far as it serves to empty the intestines of decomposing and fermenting materials which are producing autointoxication." This statement is remarkable, as he uses it, as he apparently fails to take into consideration that muscular activity and intestinal movements are as active, and indeed often abnormally so, in forcing the intestinal contents upward, if we admit the occurrence of "reversed

peristalsis," which is denied by some able observers, as in passing these contents in the normal direction. As such activity would be as fatal to peritoneal and intestinal rest as any other, he appears to be hoist with his own petard.

To return to our subject, eserine belongs to the same group of spinal depressants as pilocarpine, and one of its most marked effects, usually accomplished within fifteen minutes of its administration, is the great diminution of the activity of the spinal reflexes. It thus plainly lessens the activity of the reflex centres in which our splanchnic inhibition is generated and thus relieves the intrinsic plexuses. But this is only one of its actions. Eserine has long been known by oculists to possess a selective action upon the ciliary muscle causing a marked narrowing of the pupil, and it possesses an equal if not greater selective activity upon the intestinal musculature. Whether the action is direct upon the muscle fibre or upon the delicate nerve termination within it, is not known and does not affect our purposes. Thus, not being satisfied with relieving the intrinsic plexuses of their task, it endows their muscles with a capacity for performing far more work than is demanded of them even under such exceptional circumstances.

This process of inhibition and its combating is exactly analogous to the processes of infection and resistance, except that it is far more readily explained, in which infection figures as the analogue of the splanchnic inhibition, and resistance as the analogue of the intrinsic nervous and muscular activity.

Some have preferred, even in those cases in which none of the mentioned contraindications to postoperative peristalsis exist, to delay the administration of the eserine until a later period varying from the time of the patient's return to bed to her return to consciousness or even later, but to what purpose I have yet to learn. To me it seems irrational procrastination. What is gained by allowing the contention between activity and inhibition to go on? So far as is apparent it can result merely in the exhaustion of both, and it certainly seems unwise to weary the intrinsic plexuses and then stimulate the muscles when the former seems so easily avoidable.

If the administration of the eserine involved even one detrimental result, always be it understood in proper cases, this procrastination would be justified; but quite the contrary has been my experience. The lack of interruption of peristalsis, or its prompt restoration, has in my cases, and in those of a no less keen observer than Dr. John C. Da Costa, markedly lessened postopera-

tive vomiting, and its action, analogous to that of pilocarpine, causes a considerable degree of pharyngeal moisture which, doing away with the no longer desired throat dryness induced by the early administration of the atropine, relieves the thirst so commonly experienced.

The only untoward effect which has ever been reported to me was that of a sensation of marked weakness and muscular depression, which was very transient and occurred in a case in which no atropine was given.

It certainly seems, then, that the routine administration of eserine is justified in all cases except those stated, with the object of rendering recovery easier for all and occasionally saving a life by preventing postoperative paresis.

The concomitant treatment after the administration of the eserine differs in no way from that ordinarily followed, except as to the omission of cathartics. No such cathartic is administered by the mouth until especially indicated. In my earlier report upon this use of eserine I was quite insistent upon the use of sufficient doses to excite so active an intestinal movement as to give rise to audible or at least perceptible peristalsis. This I no longer expect nor exact, although there have thus far been no harmful results from thus stimulating the bowel, yet it is in excess of the normal activity and therefore not to be especially desired.

If normal activity is restored we have absolute indication of the fact, even in the entire absence of all rumblings, in the practically entire abdominal comfort of the patient with a soft, absolutely undistended abdomen. If a binder is employed about the abdomen it will be found too loose at the end of from twelve to twenty-four hours instead of tightly distended by a more or less tympanitic abdomen as was formerly the rule. Two explanations present for this entire lack of intestinal distention and I am unable to select the correct one. First, Wood says that eserine increases the intestinal secretions. This might lessen fermentation and so lessen distention. On the other hand, it is generally conceded that any bolus within the intestinal lumen constitutes the best of all stimuli of peristaltic contraction. Postoperative distention may, then, be due simply to fermentation or it may be nature's way of providing such a stimulant bolus. In this case the absence of the bolus is due to the absence of indication, as peristalsis is well maintained without it.

My indication for the administration of a further postoperative cathartic is the least degree of intestinal and abdominal distention, when an enema of suds, salts, and glycerin will usually be

found all sufficient. But such enema need not be given unless specially indicated. The same treatment is instituted if the ordinary symptoms of copræmia supervene, such as a coated tongue, a bad breath, or a headache. Under such circumstances if any treatment in addition to the enema seems required I usually administer a tablet containing aloin, one fifth of a grain; strychnine, one sixtieth of a grain; extract of belladonna, one eighth of a grain, and eserine salicylate, one hundredth of a grain. These may be used just as the ordinary aloin, strychnine, and belladonna tablets are used.

If the patient seems in every way well and there is no abdominal distention, there need be no haste about getting a bowel movement upon any particular day, and my charts show that the first movement has occurred at periods varying from eight hours to the fourth day after operation with no perceptible difference in the ultimate or immediate condition of the patient. Full house diet is usually allowed upon the fourth day, and if the bowels have not moved up to this time they will usually do so promptly as the result of the alimentary residue thus supplied. While in no case, since the employment of proper dosage, in which, through the immediate urgency of the symptoms, no bowel preparation has been carried out, has it failed to thoroughly evacuate all bowel contents within from eight to forty-eight hours, I do not yet feel it advisable to deliberately omit a rational bowel preparation. Any other details of management may be in accordance with the individual preferences of the surgeon and need no discussion here.

Just a word should be said, however, as to the eserine to be employed. Eserine, being as it is a vegetable active principle, an occasional failure of action may be expected, although not one has been personally experienced since the dosage of the drug has been managed as above. But certain precautions seem imperative. Only eserine (physostigmine) salicylate should ever be used. The sulphate is so soluble as to be practically deliquescent, and is extremely unstable and unreliable. The various preparations of physostigma itself should not be used, as they contain calabarine, which is strongly depressant and tetanizing, and is the portion of the drug which gave it its vogue as the "ordeal bean" of Africa.

No stock or operating room solution of the salicylate should be used, as it deteriorates in a very few hours so as to be unreliable and therefore dangerous. The hypodermic tablets of some thoroughly reliable maker should be obtained in the small tubes direct from the maker unless

every confidence is felt in the local druggist. Tablets kept in a retail druggist's stock for two months have proved perfectly active.

The most striking feature of all cases in which the foregoing suggestions are employed is the very unusual comfort and well being of the patient. Morphine has been very rarely needed or even desired, except for distinctly extraabdominal pain, but when so demanded either morphine or codeine can be given with greater freedom than without the eserine, as there is less danger of obnoxious constipation following its use.

386 COMMONWEALTH AVENUE.

Zomotherapy in Pulmonary Tuberculosis.—

Philip, in the *Practitioner*, for January, 1905, defines zomotherapy as the systematic continued exhibition of raw meat or muscle juice in the treatment of disease. Its form and dosage are to be regulated as the exhibition of any drug is regulated. It was placed on a scientific basis by Héricourt and Richet.

Its therapeutic efficacy depends on the presence of certain ferments, or on the production of certain substances resulting from the special stimulation.

Muscle tissue of all the living tissues is that on which the tubercle bacillus finds the greatest difficulty of implantation and development.

Galbraith's experiments showed that: 1. The exhibition of raw meat was followed by a marked increase of nitrogen retention, provided the heat value and nitrogen of the diet exceeded the actual requirements of the individual per kilo of body weight. 2. Intestinal metabolism was improved, an improvement which continued for some time after return to cooked meat. 3. There was a rapid increase in hæmoglobin. 4. Digestive leucocytosis was remarkably increased.

The method of treatment was as follows: 1. Pounded fresh raw beef, slightly seasoned with salt, one half pound, two or three times daily, cold or gently warmed. 2. Beef juice, one half pound of meat, one half pint of cold water, one half teaspoonful of salt, percolated through a linen cloth one and a half to two hours, at 100° F. 3. Raw meat soup made from one half pound minced fresh meat mixed to a paste with milk, one half pint of milk at 150° F. being added. 4. One to three raw eggs with salt or pepper. This treatment was very efficient in the early stages of the disease. Anæmia disappeared, the tissues became firmer, the weight increased, and the pulse rate and temperature diminished. The functions of the stomach and bowels improved, and the hæmoglobin of the blood increased. Quiescence and cicatrization in the lungs became apparent, also similar improvement in the larynx, glands, and intestine. The expectoration together with the bacilli diminished, and the same was true of the other discharges. The principal objections to this mode of treatment are the natural distaste for this form of diet and the danger of introducing intestinal parasites with the uncooked food.

THE NEW YORK BOARD OF HEALTH AND THE ANTISPITTING CRUSADE.

By WOLFF FREUDENTHAL, M. D.,

NEW YORK.

The other day when coming from my clinic I met a gentleman of my acquaintance on the street, and we walked up a few blocks together. All of a sudden I had to expectorate, and did so on the freshly fallen snow. My companion was quite surprised that I, "an up to date, progressive physician," should do such a thing. "Why," he exclaimed, "only yesterday there was a meeting of prominent medical men and all agreed as to the great danger of expectorating on the streets."

A few days later, I read in a newspaper that the war against spitters was on in earnest. Twenty-five sanitary squad policemen had been detailed to look after this class of offenders during the evenings (!) in the streets of the city, and a large number of arrests had been made! I am sure my friend was delighted over this activity of our health department, while I felt that we were wasting our efforts in an entirely useless and, what is worse, harmful manner. No doubt the majority of my readers will be surprised at the stand I take on this question, but I hope to convince them that I am right. Section 178 of our sanitary code, which I received through the courtesy of the department of health, reads as follows: "Spitting upon the sidewalk of any public street, avenue, park, is hereby forbidden." It is natural to assume that by mentioning the sidewalk first the sanitary board desired to give it the greatest prominence.

As one who has studied for years the ætiology of tuberculosis, I asked myself, Is there any real danger of infection from spitting on the sidewalk in a city like New York? As I have mentioned elsewhere, there are three possibilities to be considered here.

1. The tubercle bacilli contained in some of these expectorations could be inhaled by passers by.

2. They would stick to our shoes and would thus be carried into our homes.

3. It was stated repeatedly that women with their long skirts would sweep the streets, thus carrying the bacilli on their dresses to their houses. The person cleaning such dresses would be exposed to the danger of tuberculous infection.

As far as the writer is able to judge, about one person out of a hundred who frequent our streets is consumptive. This in itself does not make the

danger appear to us great, aside from the fact that nowadays the average physician instructs his consumptive patient that he has no right to expectorate otherwise than into his flask or his handkerchief. Furthermore, it must be remembered that street cleaners who are constantly occupied in sweeping the streets do not suffer more from tuberculosis than other people. Nor are laryngologists oftener stricken with that disease than any other class of men. This proves that the occasional inhalation of a few bacilli will not produce tuberculosis. More is required to do that.

In regard to the second point, let us suppose that somebody does step on sputum containing live tubercle bacilli in walking on the street, thus carrying them to his home. Is it in any way likely that an infection could follow? If so I want to see the first case of infection thus acquired.

Long street dresses certainly do sweep the streets and are a nuisance from every point of view. But what do they sweep up? Is it only what is deposited on the sidewalk, or more? Imagine for a moment a number of dry cold winter days, when the temperature is below the freezing point so that the streets cannot be sprinkled. The dust that is on the roadway is whirled up by the wind, by rapidly passing vehicles, etc., and is widely disseminated on the sidewalks as well as elsewhere. If live bacilli were on the streets or gutters, we ought to find them soon on the sidewalks, too. Thus the trailing dresses will gather these bacilli as well, and then there is danger not only for the one servant who cleans the dress afterwards, but more so for all the unfortunate people who have to walk behind such a dust raising woman. And the question now arises, Is it not better to prohibit long dresses on the street rather than spitting?

It is far more important that the city authorities should try to reduce the dust in the streets to a minimum. How this can be accomplished in winter I am unable to say. But whenever the temperature is above the freezing point much more water ought to be used in cleaning the streets than is the custom in this city. It is nothing unusual to see the street cleaners sweep the streets without first sprinkling them. The time they commence their work is generally when the children go to school. Thus these youngsters get a large quantity of the dust on the streets at that time into their respiratory organs. That is a real danger that should be prevented. If the men have to sweep the streets dry, then let them begin early in the morning or work during the night. If this cannot be done, it is preferable not to sweep them at all. I, for one, should prefer the

dirt on the streets to inhaling it myself or having others inhale it. The dust we get into our throats, and probably our lungs, that dust is the great danger, not the few tubercle bacilli we may occasionally inspire.

This brings us to the question: Is expectorating necessary under the conditions we live in or not? The answer is emphatically Yes! And everything that tends to suppress it will be detrimental. Whether we work in factories, offices, or in hospitals and clinics, a great deal of harmful bacteria and other foreign bodies (soot, dust, etc.) are inhaled. All this must naturally be expelled from the body, for otherwise it becomes dangerous to health. This is accomplished by the action of the ciliated epithelium. These foreign particles are carried away by the current of the cilia which swing from the bronchi towards the nares. Thus "with great intelligence" the cilia sweep out during the night the dust that is inhaled during the daytime; and in the morning it is found deposited at the entrance, when, with a little hawking, etc., it is easily removed. This is the case in many instances. There are, however, a great many people who cannot get rid of the sputum during their morning toilet. They walk a short distance, during which time it is easy for them to expel it. Now, is it not far preferable to eject this sputum into the streets or even sidewalks than into a handkerchief? In the open air the sun, even on cloudy days, or the oxygen of the air, or both combined do all to destroy the bacteria. In the pocket of a person there is every chance for drying the sputum and for the propagation of the bacilli. By repeated use of the same handkerchief the germs can be inhaled with the greatest ease. Thus the greatest danger lies in not expectorating on the street.

The board of health does not forbid expectorating, but its ordinance by creating the impression that spitting at any rate is nothing but a bad habit may work detrimentally. It has done so in cases I have come across in my practice. The majority of these people simply swallow their saliva, which is much worse than spitting on the sidewalks. They are perhaps classical examples of autoinfection.

And now to return to my personal experience with the gentleman mentioned above. He was an exceptionally intelligent man who had acquired that wrong idea about spitting through reading the orders of the board of health, and did not expectorate at all, if he could help it, not even on the middle of the street. From his point of view he was right in being surprised at my spitting on the snow in the street. But what do

we as physicians think about it? Let us consider the case once more. On the afternoon referred to I had been working for more than two hours with several assistants in a closed room of the dispensary. We had treated about fifty patients, and I myself had examined many with follicular angina, diphtheria, influenza, laryngeal tuberculosis, etc. There was no question that many infective germs had located in my throat and nose. Now should I have brought this infective material home to my family, and put the handkerchief into the dry washbasket, where the bacilli had time to develop? I believe that the danger to my family and to the community is far less if such sputum is deposited on the street and sidewalk. Of course, such pronounced cases are not of every day occurrence, and we as medical men know that an infected handkerchief should be disinfected immediately. But how many other people know and are able to do it? The majority of men who go to business in the morning, for example, would carry the infectious material in their pockets all day long. If that is not worse than to have it exposed to the germicidal effect of the air and sun, then I am free to confess I do not know anything at all about medicine.

In factories, sweatshops, and similar closed places it is entirely different. There the antispitting law cannot be enforced too rigidly. In the stations of the underground railroad nobody should be allowed to spit on the floor. But at the same time no dust should be created there by sweeping.

In conclusion I wish to say with gratitude that the horrid custom of spitting on the floor of cars, etc., is a thing of the past. But a law by which a person is dragged to court for spitting on the sidewalk is harmful. It has done harm already by producing a fear of expectorating, and is apt to hurt the masses of the population to a still greater extent in the future.

Woman Founder of Forty-six Hospitals.—The Columbus Hospital, Chicago, which was dedicated and opened on February 26th, is the forty-sixth institution of its kind which has been founded by Mother Superior Francis Xavier Cabrini, head of the order of the Missionary Sisters of the Sacred Heart. It is located at Deming Place and Lincoln Park, and formerly was the North Shore Hotel. It has been rebuilt in part and entirely refitted at a cost of more than \$30,000. Mother Cabrini was born in Lodi, near Milan, Italy, nearly fifty years ago. Pope Leo XIII. became interested in the work of the order of which she was the founder and established a home in Rome for the training of the sisters.

OPIUM SMOKING READILY CURED.

By W. H. JEFFERYS, A. M., M. D.,

SHANGHAI, CHINA,

CHIEF SURGEON TO ST. LUKE'S HOSPITAL; INSTRUCTOR IN SURGERY AND PATHOLOGY, ST. JOHN'S COLLEGE; EDITOR OF THE *China Medical Missionary Journal*.

It is not perhaps generally known that "foreign civilization," after being largely responsible for the spread of opium smoking among the Chinese, has been, on the other hand, in a measure responsible for the introduction and now awaits the general adoption of a readily administered and positively efficient cure for the habit.

Morphine is the remedy which is sold in China at the present time as a foreign "sure cure for the opium habit," and a good profit¹ it brings to the manufacturer and to the retailer, for it easily takes in both the dollars and the Chinese. This trade is not, I believe, carried on by any of the respectable druggists in the treaty ports, but is in the hands of dispensaries owned by more or less irregular persons, foreign and Chinese, who handle chiefly patent medicines. (Therein also lie numerous and surprising tales.) It is not necessary to add that morphine proves itself, as advertised, an easily administered and sure cure for the opium habit and gives pretty general sat-

isfaction. Of course it invariably substitutes a well developed morphine habit for the original disease, and this former is in my experience less hopeful of cure than the latter, and the margin of hope in the case of opium is rather to be measured with the micrometer than with the yard stick.

The inevitable result of this practice is an ever increasing number of Chinese with a chronic morphine habit. If it has been acquired in the manner referred to, it may be continued by consumption of the morphine pills, or by hypodermic medication as securable in many of the up to date opium shops and tea houses of Shanghai and the treaty ports. On the other hand, the morphine habit may have been acquired directly in the opium den, even as a primary affection.

It is not easy to gather reliable information concerning these matters. For a foreigner to appear in person would, in the treaty ports, be fatal to the attempt. Some facts, however, come to us directly in connection with our work. Morphine is indulged in largely, not only by the well to do, but also by the coolie class who pay as little as 14 cash (one cent, American) for an injection, which is of sufficient strength to satisfy the ordinary consumer. It is probable that this morphine, so cheap is it, is prepared in Shanghai from the native drug. The well to do may own their syringes and learn to use them with some faint regard to asepsis, or, rather, cleanliness, but in the common shops there is no slightest attempt made to protect the victim. The syringe shown in the photograph (Fig. 1) is of native make. It is an exceedingly crude affair when viewed from our standpoint, though copied from a foreign model, and the needle projects only one eighth inch and in use is jabbed up to its hilt in the skin of the arm or leg. The instrument, the hands of the operator, and the skin of the patient are not cleansed in any way whatever.

The syringe is made of four or five different metals and fits into a rough bamboo case; the morphine is kept in an empty old brass rifle cartridge with a rolled paper stopper. All these are filthy. This instrument I bought from an opium den in Shanghai, and had to pay a good price for it, too.

As a conclusion from these premises, the immediate or ultimate infection of the part is assured. Two of my cases are here illustrated. In both instances treatment was asked for the infective process, not for the morphine habit.

CASE I (Fig. 2).—A coolie; presented himself for the treatment of three medium sized carbuncles on his back. They were of average se-

FIG. 1.—A Chinese hypodermic needle. The four native knives shown make up a set for use upon the toes and toenails, especially in the treatment of corns. The six needles are the commonly used Chinese acupuncture needles. Thereby hang many thrilling tales. I have treated panophthalmitis due to the passage of such a needle clean through the eye in the treatment of trachoma. One man presented himself to me for radical cure of berrials. He "had been operated upon by a native doctor who had passed several needles through his tumor but had not cured it." The fact that these needles are usually heated before use will explain his "being still about."

¹ One dollar, Mexican currency, about fifty cents, buys a box of sure cure pills.

FIG. 2.—Scar tissue, furuncles, etc., caused by septic hypodermic syringe.

verity, but so constantly and deeply under the influence of morphine did the patient keep himself that he made no complaint of pain either in the tumors or in the arms or legs of which the extensor surfaces were a mass of scar tissue, active furuncles, and ulcers. The position of the carbuncles interfered with his work, which consisted of carrying heavy loads on his shoulders. We made crucial incisions in all three swellings without the patient's seeming to suffer at all. Patient refused to be admitted to the wards, and declined to allow us to try to break up his habit which he "enjoyed," and did not wish to be deprived of. His general condition was septic, and mentally he was dead. Patient probably died at home.

CASE II (Fig. 3).—Was also a coolie. His

FIG. 3.—Cavity following slough from septic cellulitis.

arms showed the same scarred and actively inflamed condition. (Apologies are due for the poor focusing of this photograph.) The dark surface over the shoulder is the cavity left after the separation of a large slough, due, of course, to septic cellulitis. Recovery from condition took place with much scarring.

Scientific medicine is putting up a good fight in China, and the old empiricism of the empire is campaigning on Kuropatkin's methods, but this morphine guerilla business is not the first thing of the kind that I have reported as found harassing our Ouyaman rear guard.

SUBCUTANEOUS INJURIES OF THE ABDOMINAL WALLS AND VISCERA.

By DANIEL N. EISENDRATH, A. B., M. D.,

CHICAGO.

(Concluded from page 474.)

RUPTURES OF THE SPLEEN.

CASE I.—Boy, 16 years of age, had a monkey wrench thrown at his abdomen during a fight. Stated that he was struck over the left hypochondriac region, and there was a slight ecchymosis at this point. He fainted immediately after the accident, but recovered rapidly, and was admitted to the hospital two hours after the injury, but was not seen by the writer until ten hours after the injury, when an immediate laparotomy was made. I found upon examination before operation that he was extremely pale, pulse 96, very soft; there were tenderness and rigidity over the left hypochondriac region, and dullness in the flanks. The anterior border of this dullness changed somewhat with change of position, indicating that some of the blood was still fluid. There was considerable tympanites, and the tenderness was becoming more marked, all over the abdomen, indicating a beginning peritonitis. The incision was made in the left border of the left rectus muscle, beginning at the costal arch. Enormous quantities of fluid and clotted blood were removed from the peritoneal cavity, and a rupture of the lower border of the spleen extending towards the hilum was found to be the source of the bleeding. Several attempts were made to suture this, but were of no avail, and splenectomy was performed. He made an uneventful recovery from the operation for the first thirty-six hours, but from that time until the time of his death, on the third day, the pulse began to rise rapidly, and the symptoms of peritonitis recurred. The autopsy by the coroner showed a septic peritonitis. The writer feels confident that if he had been able to operate upon this boy within two to four hours after the injury, recovery would have followed.

CASE II.—An Italian, unable to speak English, was admitted to my service with the following history, which I personally obtained from his friends: He had been ill for two days with pain in the abdomen, which both the patient and his friends told me was most marked in the right iliac region. Pulse was 110; temperature 102°, and

there was considerable tympanites. He was extremely pale. I diagnosed the case as one of appendicitis with probable septic peritonitis, and had the patient prepared for operation. Just before the latter I learned from my house surgeon that he had been told by another friend of the patient's that the condition did not start spontaneously, but that he had been run over two days before the time we first saw him. Although I felt that in this case the outlook for operation was exceedingly dark, I nevertheless felt that there was a slight chance for recovery. I made an incision over the region of the spleen, where the friends said the wheel had passed over, and found in addition to enormously distended coils of intestine a large amount of clotted and fluid blood in the free peritoneal cavity. This was rapidly removed, and it was found there was an extensive laceration of the spleen. The splenectomy was exceedingly difficult on account of the distention of the bowel. After the pedicle of the spleen had been firmly tied and the organ removed, the bleeding still continued, and seemed to come from the beginning of the mesentery at the left side of the second lumbar vertebra. I attempted in vain to insert forceps and tampons in this direction, and was compelled to desist from further operation on account of the condition of the patient, who died shortly afterwards. The coroner's autopsy showed a tear of the mesentery involving the superior mesenteric artery. This case emphasizes the importance not only of early diagnosis, but of obtaining as accurate a history as possible of the mode of injury, which latter is at times difficult in foreigners.

CASE III.—Rupture of the kidney. This patient was a man, 40 years of age, who was crushed between a heavy packing case, which fell across his abdomen, and a projecting piece of iron which pressed upon his lumbar region. When admitted to the hospital, he complained of severe pain over the left lumbar region, and was suffering from considerable shock; he was moderately pale; pulse 100. There was a distinct swelling over the region of the left kidney, and in place of the normal resonance of the descending colon in the space between the left costal arch and crest of the ilium there was dullness, which, however, did not change with change of position of the patient. The first urine voided after the accident consisted almost entirely of blood. On account of the favorable prognosis in these cases of rupture of the kidney, under expectant treatment, an ice bag was applied over the left renal region, and the patient carefully watched for evidences of increasing hemorrhage. He was given a drachm of fluid extract of ergot every four hours. The area of dullness in the flanks did not increase during the following twenty-four hours, his general condition improved greatly, and in place of fluid blood the urine contained worm-like clots, which were passed with symptoms of renal colic. The hæmaturia gradually decreased; the urine was practically clear within forty-eight hours. This case was undoubtedly one of rupture of the kidney with recovery under expectant treatment.

CASE IV.—Extraperitoneal rupture of the bladder. The patient was a boy, 5 years of age, who had been run over by a street car, the wheels passing across the region of the pubes. He was seen by me twenty-three hours after the injury in consultation with Dr. M. L. Goodkind, who had seen him one hour previously. Dr. Goodkind had made a diagnosis of rupture of the bladder, on account of the presence of dullness extending from the umbilicus on each side to the anterior superior spine of the ilium, so that the entire lower half of the abdomen was dull on percussion. This dullness did not change on turning the patient. Attempts to catheterize the patient were followed by the escape of a few drops of bloody urine. Pulse was 140, and the distention of the bowel interfered considerably with breathing, which was rapid and shallow. Temperature was 101°. Before proceeding to operate, I thought that I would make a final test by means of injecting four ounces of boric acid solution into the bladder through a catheter. The catheter was inserted and apparently seemed to enter a cavity corresponding about in distance from the external meatus, to the bladder. Four ounces of boric acid solution came back through the catheter, stained with blood. I mention this test to show how fallacious it may be, as referred to under the head of diagnosis, and that not too much reliance should be placed upon it in a diagnosis of rupture of the bladder. If it had not been for the presence of dullness above the pubis, and evidences of beginning sepsis, I would undoubtedly have left the case to its certain fatal outcome. However, I made an incision above the pubis, and upon opening the pelvic cellular tissue, a considerable quantity of fluid escaped. This had pushed the peritonæum covering the bladder up to the level of the umbilicus, and infiltrated the anterior abdominal wall up to the level of the external dullness. A separation of the symphysis pubis was readily found, and a perforation of the anterior wall of the bladder just opposite this fracture of the symphysis. The perforation was sutured; no attempt was made to correct the deformity caused by the separation of the pubic bone. Further exploration showed a complete rupture of the membranous portion of the urethra, so that the bladder lay practically free in the pelvis, and the cavity into which the four ounces of boric solution used as a test had escaped was a free space beneath the pubis and in front of the bladder. The catheter had never entered the bladder at all. The bladder was brought up into the incision in the abdomen and sutured. A rubber tube was inserted into it, and the extraperitoneal tissue drained with gauze drains. A perineal section was then performed, and the catheter introduced through the intact portion of the urethra across the intervening gap, where the membranous portion had been torn, into the bladder, it being necessary to introduce it from the bladder outwards (retrograde catheterization), on account of the difficulty of finding the proximal end of the urethra. This is a far more rapid way of finding the bladder end of the urethra, and greatly facilitates the operation. The boy made an uneventful re-

covery, but a stricture still remains at the point of the rupture of the urethra, which it will not be possible to deal with until the boy is old enough to have sounds introduced for the purpose of dilating the same.

CASE V.—Extraperitoneal rupture of the bladder. My chief reason for publishing this case is for the purpose of emphasizing the necessity for looking for ruptures of the viscera when least expected. A Bohemian child, 3 years of age, was admitted to my service with the following history: Six days before, the child, while its mother was away from the house, had fallen from a high chair to the floor, where it was found by the mother. The mother did not observe any immediate effects, and it was only after the second day that she noticed the child did not seem as well, and that the right side of the abdomen was gradually swelling. When admitted to the hospital, on the sixth day after the accident, the temperature was 102.6° ; pulse, 150. The child looked septic. Examination of the abdomen showed a doughy infiltration of the skin, more or less limited in front by the median line, and extending posteriorly almost to the spine. Downwards, it extended as far as Poupart's ligament, and upwards towards the clavicle, there being marked oedema of the mammary region. The child was catheterized and clear urine obtained, three ounces each time. There was dullness over the right half of the abdomen from the Poupart's ligament to the costal arch, merging into the liver dullness. This did not change on moving the patient. Every symptom pointed to a rupture of the bladder into the pelvic cellular tissue, but the clearness and quantity of the urine were puzzling, and rather contradictory of such a tear. Although this case also seemed hopeless, I made an incision above the pubis and found a considerable distention of the bladder, and an enormous infiltration of the tissues of the anterior abdominal wall and right half of the pelvis with urine. Examination of the bladder showed a tear in all of the coats of the viscus, except the mucous membrane, just opposite the brim of the pelvis, and after sponging away the urine one could observe how it escaped through this pseudofilter drop by drop. This is not the first case which has been described in which only a partial rupture of the coats of the bladder has occurred, the effects being equal to those of a complete rupture.

I was at first puzzled to know how this injury could have occurred, but upon remembering that the bladder in children is almost entirely an intra-abdominal organ, one can readily understand how a child of this age can have fallen with its bladder full of urine and the organ strike upon the pelvic brim, opposite which we found the rupture. The extraperitoneal tissue was drained, and a number of incisions were made into the infiltrated abdominal wall, but were of no avail, the child dying after a few days.

CASE VI.—Subcutaneous rupture of the abdominal wall. This patient was a man, 40 years of age; he was admitted to my service, after having been crushed between two street cars pass-

ing in opposite directions. He was admitted to the hospital, suffering greatly from shock, and was seen by me about two hours after the injury. A diagnosis of traumatic hernia situated over the middle of the crest of the ilium had been previously made by my house surgeon, Dr. Snyder. Over the point just described there was a tumor about the size of two fists, which was tympanitic on percussion, and which could be readily reduced into the abdominal cavity with a gurgle, similar to that obtained in the reduction of a hernia. After this manipulation a gap could be found in the muscles just above the crest of the ilium. In addition to this injury, there was a fracture of the clavicle and of the fifth and sixth left ribs. The patient had recovered somewhat from his initial shock, but would not consent to operation until the following morning, fifteen hours after the injury. An incision made parallel to the crest of the ilium showed that all of the abdominal muscles attached to that crest from a point corresponding behind to the erector spinæ had been torn off, and the same condition existed as far as the middle of Poupart's ligament, so that upon incising the skin one entered at once into the general peritoneal cavity, where a number of loose pieces of omentum were lying in a cavity which had been formed through adhesions of the ascending colon to the anterior abdominal wall, thus separating the area of the injury in great part from the general peritoneal cavity. There was a slight contusion of the ascending colon. The abdominal muscles showed along their free edges evidences of extensive laceration. By means of fourteen kangaroo tendon sutures inserted in mattress fashion, the torn muscles were brought down and anchored to the gluteal fascia as far as the anterior superior spine of the ilium in front, and from that point to the middle of Poupart's ligament they were sutured to the shelving edge of that structure, in a manner similar to that used in the Bassini operation. The patient made a rapid recovery, and examination one year after the injury shows that there is no recurrence of the hernia. This case is one of the first to be published of such extensive laceration of the abdominal muscles without external signs of injury, other than the slight hernial protrusion which upon first examination resembled somewhat a blood clot, and could only be distinguished from the latter by careful manipulation.

103 STATE STREET.

Ulster County, N. Y., Medical Association.—

The annual meeting of this association was held at the Kingston City Hospital on February 20th. The following officers were elected for the ensuing year: President, Dr. J. L. Preston; vice-president, Dr. Frederick Huhne; secretary, Dr. Mary Gage Day; treasurer, Dr. Alice Divine, of Ellenville; member of the executive committee at large, Dr. C. V. Hasbrouck, of Rosendale; member of the nominating committee to the Fifth District Branch, Dr. J. Preston, of Milton-on-Hudson; fellow to the State Medical Association, Dr. A. H. Palmer, of Marlborough; alternate, Dr. E. Osterhoudt, of Plattekill.

TUBERCULOUS MENINGITIS WITH CONGENITAL STRICTURE OF THE RECTUM. CLINICAL AND PATHOLOGICAL REPORTS.

By HENRY S. WIEDER, M. D.,

PHILADELPHIA,

AND

HAROLD L. SPRINGER, M. D.,

WILMINGTON, DEL.,

FORMERLY RESIDENT PHYSICIANS OF THE PRESBYTERIAN HOSPITAL OF PHILADELPHIA.

The following is a brief report of the clinical history and the pathological findings of a case of tuberculous meningitis with congenital stricture of the rectum.

The tuberculous meningitis occurred in a child four and one half years of age, with a family history containing a record of tuberculosis on the mother's side in three members of the family. Of bearing in the previous medical history was the fact that she was very obstinately constipated during the first six months of her life, never obtaining a bowel movement except by artificial means. Also is to be noted the fact that her cervical glands were much enlarged the winter before her death:

For a couple of weeks before admission the child complained of being tired and sleepy. This was followed a week later by profuse nosebleed and pain over the root of the nose. Later she vomited frequently, held her arms up behind her head and complained of pain on straightening them out. She began to suffer with fever five days before admission, became peevish, complained of noise, and shrieked out at times. She became stuporous the day before admission.

On admission to the hospital on May 19, 1903, the child was stuporous, slow to obey instructions, would not talk, and refused nourishment. Her pupils were equal and not dilated, responding to light; no strabismus present; tongue, moist brown coating, no tremor; pulse small, soft, not dicrotic, 128; heart and lungs normal; liver extended to one finger's breadth below the edge of the ribs; abdomen soft, no distention, no spots; spleen not enlarged or palpable; legs, no oedema, tremor, or rigidity.

On successive days she developed symptoms in the following order: increasing stupor, tendency to retraction of the head, lead pipe movements of all the joints, imperfect Koenig's sign, internal strabismus, inequality, dilatation, and immobility of the pupils, doubtful Babinski's reflex, *tâche cérébrale*, rolling of the eyes, difficulty in swallowing, pulse of 200, and oedema of the lungs; death soon followed. She frequently uttered a shrill cry. Twice, on the 12th instant, on being turned on her side, she developed a convulsion, her right foot shooting backward with opisthotonos and retraction of the head. Both were of very short duration. Her leucocytes were between 19,000

and 42,000 and her Widal reactions were negative.

Four spinal punctures were performed, obtaining the following amounts of a clear, colorless fluid: 20 c.c., 35 c.c., 3 c.c., and 11 c.c. After the first two punctures there was an apparent decrease in the severity of the symptoms. Tubercle bacilli were not obtained from the spinal fluid.

The temperature never reached above 102.1°, except the terminal temperature, which rose to 105.1° at 5 p. m., the patient dying at 11 p. m. The temperature had touched normal on two different occasions.

NECROPSY REPORT.

Upon removing the skull cap the dura was found not to be adherent to it. Upon opening the dura there was an escape of a considerable amount of cerebrospinal fluid. The pia mater of the base was thick and opaque, with some pus under it. Around the optic chiasm on the vessels about the circle of Willis were numerous small bodies the size of mustard seeds and much resembling miliary tubercles. These were more numerous along the Sylvian artery. The section of the brain showed nothing abnormal except dilatation of the ventricle from excess of cerebrospinal fluid. There were no tubercles upon the chorioid plexus.

In the anterior mediastinum, just under the first portion of the sternum, was a large and softened lymph gland that on section was found to contain a yellow purulent fluid probably tuberculous. The bronchial lymph glands were much enlarged, but the lung showed no evidence of tuberculosis.

The heart was normal except some cloudy swelling of its muscle.

The liver, kidneys, pancreas, adrenals, and stomach were all normal.

There were irregular areas of congestion of the large bowel which appeared to be somewhat hæmorrhagic in places, but with no ulcers.

In the rectum, three inches from the anus, was a constriction of the bowel. The bowel appeared to be somewhat thickened, and the interior of the constricted portion was white and hard and marked by longitudinal striations. There was no dilatation of the bowel above this point. Above this point was retained a quantity of nutritive enema which had been given on the day of death.

Pathological Diagnosis.—Tuberculous meningitis; cloudy swelling of the liver, kidneys, and heart; congestion of the lower bowel; and stricture of rectum.

MICROSCOPICAL REPORT.

The bronchial lymph glands showed tuberculosis in the stage of caseation. One had gone on to pus formation.

A section was cut from the middle of the constricted area in the rectum and examined microscopically with the following results: The mucous and submucous layers of the rectum were almost entirely absent, there being a congestion only of the mucous membrane present. The muscular coats were entirely absent. A growth of fibrous tissue had taken the place of these normal layers,

so that the section seemed to be one of fibrous tissue instead of intestinal wall.

The absence of inflammation of the rectum, as evidenced by the previous history and microscopical examination and the history of constipation during the first six months of life, make it probable that the stricture was congenital. The fact that no further difficulty was experienced after the first six months may be explained by a compensatory hypertrophy of the bowel immediately above the site of stricture.

A STUDY OF THE STOMACH FUNCTION IN PULMONARY TUBERCULOSIS.

By J. F. MUNSON, A. B.,

ANN ARBOR,

FROM THE MEDICAL CLINIC, DEPARTMENT OF MEDICINE AND SURGERY, UNIVERSITY OF MICHIGAN.

Dyspepsias have long been recognized as common accompaniments of the tuberculous process, in all its stages, and are characterized by the ordinary symptoms of gastric disturbances. Certain stages of these dyspepsias are spoken of, the terminal and the initial, one form of which has been brought into especial prominence; namely, a form of beginning tuberculosis in which stomach symptoms alone are noted by the patient, who thus comes to the physician with a stomach case.

We have two distinct indications, calling our attention to the stomach in lung tuberculosis. First, we need its assistance in the problem of better nutrition; and, second, we must relieve the gastric disturbance. To meet these indications intelligently, we must have an exact knowledge of the activities of the stomach—a knowledge which can only be ascertained by examination of the stomach contents after test meals of known stimulation.

It was suggested to me by Dr. Dock, that a study of the stomach function in pulmonary tuberculosis, as observed in this clinic, and a review of the literature on this subject, would be an instructive bit of work. I wish to take this opportunity to express my thanks for the advice and assistance I have received from Dr. Dock and from Dr. Cowie, who has charge of the stomach work in the clinic.

The subject has already been investigated by several authors.

Brieger (1) reports 64 cases, on which 300 separate examinations were carried out. He divided his cases into three groups, advanced cases, cases of moderate intensity, and beginning cases. The stomach contents in the advanced cases (31 in number) were always acid after the test meal and mostly also after the test breakfast, though in some cases neutral juices were obtained, by rea-

son of the admixture of alkaline sputum. The acidity after the test breakfast was between 14 and 56, and after the test dinner 69; the values of these being respectively 0.05, 0.09, and 0.24 per cent. In the first group, free hydrochloric acid was always present in three of the cases (to which should be added two cases in which the occasional lack of hydrochloric was due to alkaline sputum), and was always lacking in 19. In seven cases, free hydrochloric acid was at times present. There was no relation to fever. Rennet was absent with lack of free hydrochloric acid. The second group contained twenty-seven cases; of these, fifteen showed the constant lack of hydrochloric acid, and nine its constant presence. The secretion was variable in the other three. The group of beginning cases showed hydrochloric acid constantly absent in three and present in the same number. In this and in the preceding group, the ferments and their zymogens were always present; in cases with great disturbance of the chemical composition of the juice, there was considerable lessening of the motor power.

Brieger summarizes his findings as follows: In severe phthisis, the chemical composition was normal in 16 per cent., and in the remainder of the group a greater or less insufficiency; in 9.6 per cent. the secretory products were absent. In the intermediate cases, the findings were normal in 33 per cent., a lack of secretion in 6.6 per cent. and a varying intensity in the remaining cases of this group. One half the beginning cases were normal. The motor power is impaired in proportion to the chemical disturbance. The admixture of sputum may change the reaction. The relation of fever to secretion is not well established. The restoration of anorexia did not cause the re-appearance of free hydrochloric acid; but in two cases, the appearance of fever corresponded with the disappearance of previously present hydrochloric acid.

Klemperer (2) reports 14 cases. The secretions were obtained after a meal of milk and rolls; the motor power he tested by giving 100 grammes of oil; two hours later, all that remained in the stomach was removed and measured. In the initial group he places 10 cases, two of which he sub-groups as pretuberculous dyspepsias. Of the remaining four cases, three are classed in the terminal group and one intermediate between the two groups. In the cases of pretuberculous dyspepsia, the average free hydrochloric acid value was 1.84 parts per thousand; the average total acidity was 2.84 parts per thousand and the oil recovered was 50 c.c. In the remaining 8 initial

cases, the average acidity was 2.4 parts of hydrochloric acid per thousand, and the total acidity 2.84 parts per thousand; the oil recovered amounted to 36.44 grammes. The intermediate case showed a hydrochloric acid value of 0.38, after a meal of milk alone. In this case there was considerable food in the stomach seven hours after the midday meal. The advanced cases were marked by "lessening of the motor power, dilatation, and fermentative processes." "In all cases of phthisis, the diminution of the motor power is slight at first and marked in the later stages. The secretory activity is at first normal or increased; in the end, greatly diminished."

Hildebrand (3) reports some cases in which the relation of hydrochloric acid to fever is especially noted. He divides his cases into groups according to the temperature. In one group (a. m. temp. 36.8° C. to 37.4° C.; p. m. temp. 36.7° C. to 37.8° C., and in one case 38° C.) he found hydrochloric acid constantly present. In another group, with a temperature always above 38° C., he found hydrochloric acid always absent. In a third group, in which the fever was not always present, it was noted that hydrochloric acid was lacking with high evening temperatures and present with low. He concludes that hydrochloric acid is not found with temperatures above 37.8° C.

Cahn and von Mering (4) report the case of a young consumptive, having fever and amyloid cachexia, who was examined twenty-six hours before death. With milk as food, his stomach contents gave a hydrochloric acid value of 0.4 parts per thousand, and 0.54 parts per thousand of lactic acid.

Schetty (5) reports 25 cases which may be summarized as follows:

	Hydrochloric acid (per cent.).		
	Average.	High.	Low.
In 6 incipient cases.....	0.175	0.31	0.10
In 19 of long duration:			
2 without fever.....	0.195	0.25	0.14
9 with evening fever only.....	0.203	0.4	0.10
and 8 with morning and evening fever.	0.20	0.29	0.10

He says that in all cases the reaction of the stomach contents was acid, due to hydrochloric acid, the production of which was not diminished and was even increased. There was a normal amount of hydrochloric acid in the advanced cases and in those with morning fever. The digestive power of the juice, for albumin, appeared about normal. There seemed to be no motor insufficiency following the midday and evening meals.

Rosenthal (6) has prepared a brief review of the preceding investigations. In this he adds, parenthetically, that he has been unable to find free hydrochloric acid in a number of cases of consumption. This refers to a report (7) in

which he says: "It is established that the stomach contents of patients with clearly recognized tuberculosis, both in early and advanced stages, contain no free hydrochloric acid, though appetite and digestion appear normal." His table shows the acidity from 2 to 7.

Immermann (8) studied the function of the stomach, using consumptives of all grades. He first studied the motor power; giving a Leube's test meal at midday and withdrawing it in from six to seven hours. In 51 out of his 54 cases, the stomach was empty after six hours, and in two of the other cases contained only a little fluid. A second investigation consisted in the study of the morning secretion, obtained after a test breakfast composed of the whites of two hard boiled eggs, with 100 c.c. of distilled water. In normal cases, this meal yielded a considerable quantity of sour fluid contents, with undigested egg. Gunzberg's test was very strong and titration with N-10 sodium hydroxide solution gave an acidity of 1 to 2 parts per thousand of hydrochloric acid, not often so small as 1 and often more than 2 (2.2 to 2.3). Consumptives gave homologous results. The contents with one exception contained only egg particles; 38 cases out of 44 in this series showed from 1 to 4 parts per thousand, with an average value of 1.9. "It was of special interest to note high hydrochloric acid values in decrepit patients, in whom one would least expect it. In six of these cases, Gunzberg's test was negative; in two the contents were weakly alkaline. In four cases, the contents were acid, but the acidity was not due to organic acids." He assumes this acidity to be due to hydrochloric acid and that the contents of the stomach were withdrawn at a time at which no free hydrochloric acid existed.

He continues: "Taken all in all, I do not think that these few exceptions speak much against the rule, that the morning value of hydrochloric acid is not inferior, in general, to that of health." He farther found that the time consumed by the digestive juices of consumptives, in digesting an egg disk (6 mm. x 1 mm.) was 1½ hours; where healthy juices required one to two hours for the same purpose. He regards the dyspepsias of phthisis as complications, and not as attributes of the disease.

Von Ruck (9) speaks of cases in which he "found no free hydrochloric acid in the stomach contents two hours after trial meals." He also speaks of cases in which there were hyperacidity and markedly increased motility.

Hayem (10) reports a number of cases of incipient and advanced tuberculosis. Of 32 incipient cases, 15 showed hyperacidity, 16 hypo-

acidity, and 2 apepsia. In 48 cases of advanced disease, 15 showed hyperacidity, 38 hypoacidity, and 12 hypoaclidity to apepsia.

Einhorn (11) studied some 15 cases of this kind, using Ewald's test meal. Of these, free hydrochloric acid was absent in two cases and once out of three examinations in a third case. In all other cases, free hydrochloric acid was always present. Concerning the degree of acidity, 5 were found to have a normal acidity (50 to 54), 5 others were above normal (50 to 72), and 5 cases showed a diminution of acid (46 to 15). Retention was noted only once in all the examinations, so that one may assume that the stomach was empty before taking the test meal and that, therefore, the motor power is not disabled. Appetite is not correlated with the hydrochloric acid and total acidity. He also suggests that the sputum swallowed by the patient may be the cause of the dyspepsia, by irritation of the gastric mucosa.

A reclassification of Einhorn's cases, according to duration, gives 8 cases, of from 6 to 9 months' duration and 7 of from 1 to 2 years. In the first group, the highest total acidity was 70, the lowest 50, and the average 58.9. In the second group, the average was lower—33.8, the highest being 70, the lowest 15.

Gluzinski (12) in a study of the stomach's condition in various fevers, reports among others, a case of double apical tuberculosis. In this case the highest morning temperature was 37.5° C., the highest evening temperature was 39.7° C. The average quantity removed after test meals was 125 c.c., and the highest acidity was 16; the digestive power appeared normal.

Fenwick (13) speaks of some instances of dyspepsia preceding phthisis, in which "the hydrochloric acid of the gastric juice appeared to be secreted to an abnormal extent." As a rule, he found the secretions diminished in the later stages of the disease. Fenwick believes that this form of inquiry (i. e., stomach examination) has no clinical value in phthisis. For not only does he look on the hydrochloric acid values as varying from day to day, but the degree of acidity and the severity of the symptoms are not correlated. He has repeatedly observed that with continued pyrexia and diminished hydrochloric acid, digestion was carried on with less subjective distress than in another possessed of normal temperature and hydrochloric acid. This apparent discrepancy he explains by the presence of sufficient combined hydrochloric acid for the purposes of digestion.

Bordoni (14) says that the lack of hydrochloric acid occurs in tuberculosis, among other diseases.

Chelmonski (15) in 8 out of 11 cases of this disease failed to find free hydrochloric acid. There was retention in two cases. It is interesting to note in passing that in 15 cases of emphysema with cedema, dyspnoea, and chronic bronchitis which he reports, there was none which showed free hydrochloric acid. It is especially interesting to note that in two of these cases, the symptoms cleared up and the gastric juice was then normal. Chelmonski seems to think the stomach condition a result of circulatory disturbances in the gastric mucosa, due to the disturbance of the pulmonary circulation. He concludes that there is a lack of free hydrochloric acid in pulmonary tuberculosis independent of fever; and that there is often a lack of hydrochloric acid in emphysema.

Robin and Du Pasquier (16) studied 85 cases, using a test meal of egg, bread, and water, removed in one hour. In beginning cases they find that 69 per cent. have hypermotility and hyperchlorhydria; the hydrochloric acid values are never very high and rarely exceed 1.5 parts per thousand; there was hypomotility in about 19 per cent. and about 12 per cent. have normal hydrochloric acid values. The second stage is a transitional one, in which the secretions are variable. The terminal period, the time of cavity formation, is characterized by mucous degeneration and atrophy of the gastric glands, and by hypo- and anachlorhydria (0.76 per cent.). They describe these changes as a gastric cycle, following the course of the disease, even to the abolition of function.

Reed (17) reports a case of consumption which presented stomach symptoms only, showing hyperacidity, which at times exceeded 0.1 per cent. of acid. He concludes that in early stages of pulmonary tuberculosis, the secretion of hydrochloric acid is often excessive and that the motor power is decreased.

Grusdew (18) found hydrochloric acid lacking three times out of eighteen examinations, in mild cases.

Bernstein (19), in 17 cases, found that hydrochloric acid was more often lacking in cases without fever (7 out of 9) than in those with (4 out of 8). The total acidity was mostly lowered, as was the hydrochloric acid content; there was never hyperacidity.

Croner (20) used the Ewald meal. He says there was no weakening of motility, having recovered, on the average, 300 c.c. The total acidity was between 21 and 80, mostly normal, but more often too low than too high. In 5 out of 36 cases, there was no acidity. He found no relation between the subjective and the chemical conditions.

In regard to the fever, he says it has some effect on the acidity, but that he cannot make a definite rule; there are cases showing no fever, in which no acid was found; the upper limit set by Hildebrand, for the secretion of hydrochloric acid, namely, 37.8° C., is too low.

I think that a short summary of the above will be useful for purposes of comparison with the cases I have to report. Brieger and Klemperer find the motor power of the stomach weakened in proportion to the chemical change. On the other hand, Schetty, Immermann, Einhorn, and Croner, find no weakening. As to the acids, Brieger, Klemperer, Fenwick, and Robin and De Pasquier, find a diminution proportional to the disease; all but the former reporting hyperacidity in the early stages. Croner and Immermann found the acidity mostly normal, while Rosenthal, Bordoni, Chelmonski, and Bernstein, often found anachlorhydria.

As a preface to the reports of the analyses which have been gathered from the records of consumptive patients treated in Professor Dock's clinic, it may be well to say a few words in explanation of the methods used. The text breakfast employed is either the "granose" or the "shredded wheat biscuit" meal, composed of 37 grammes of granose or one shredded wheat biscuit (weighing from 33 to 35 grammes) and 300 c.c. of water. It is customary to give this meal between 6.00 and 7.00 a. m., the patient having received neither food, drink, nor medicines after midnight. The meal is removed by aspiration one hour after the patient begins to eat. The acids are estimated by Töpfer's method,¹ and the results reported in terms of c.c.

¹A slight modification of the Töpfer method is used—namely, that, when titrating with phenolphthalein as an indicator to determine the total acidity, the end reaction is taken as the first permanent appearance of pink, instead of the deepest cherry obtainable, of N-10 acid in 100 C. C. of the filtered gastric juice. For some time pepsin and pepsinogen have been tested for after the Mett method, this method having superseded the employment of egg disks and fibrin. I also report the patient's temperature on the day of the meal and on the preceding day.

In arranging the cases for study, I have adopted the classification outlined above in the report of Brieger's work (page 2). Such a classification must, of course, be somewhat arbitrary; where there was doubt as to the group to which the case belonged, it was placed in the intermediate group. The probable duration of the disease is estimated from the history given by the patient; the physical examination of the stomach, at the time of the taking of the status præsens, furnishes the data, regarding its position and size. The following tables give a detailed analysis of the individual cases:

Before proceeding to draw conclusions from these cases, I think that it will be well to summarize the condition in each group.

Table I.—Group one includes ten cases early in the disease. The *duration* does not exceed nine months. In eight cases there is a history of *stomach symptoms*, which in some cases antedate the lung condition and in others introduce or accompany it. The *motor power* was on the average about normal, about 52 c.c., being recovered at the end of an hour. There was some retention in one case, having a history of stomach trouble of three years' duration; in two other cases there was variable motor power, each showing decreased motor power in one test meal out of three. In four cases *hydrochloric acid* was always found, in one it was always absent, and in five it was at times found, at others absent. In amount, the free hydrochloric acid averaged 30.3, the highest being 75 and the lowest 4. The *total acidity* ranges between 88 and 5, the average being 39.6. In five out of 17 estimations of *combined acid*, the average value was 19; in the other twelve it averaged about 6.6. In summing up the condition in this group, I would say that two cases showed an approximately normal acidity, one hyperacidity, two distinct hypoacidity, and the remainder a condition of hypoacidity, sometimes becoming anachlorhydria. The *peptic digestion* seems unchanged.

Table II.—Group two contains eleven cases of intermediate severity, with 16 examinations. The *duration* of the disease is five months to two years. The *quantity* recovered at the end of the hour was

78.7 c.c. *Hydrochloric acid* was present in every examination in 6 cases, constantly absent in 3, variable in one, and doubtful in one. The highest value of free hydrochloric acid was 38, the lowest 5 and the average of the examinations about 15. The *total acidity* varied between 5 and 56, the average being 32.5. When estimated, *combined acid* was low (average = 10), except in one case where it reached a value of about 17. *Peptic digestion* appears undiminished in this group.

Table III.—Group three contains 5 cases of advanced tuberculosis with 9 examinations. The quantity of stomach contents recovered was 43.5, one case showing once a value equal to 100 c.c. The qualitative tests for free hydrochloric acid were present once, at times found in two, and absent in two others. The hydrochloric acid did not exceed 22 nor fall below 10, when present. The average of the combined acid tests was 12. The average total acidity was 33, the highest being 90, in a case which also showed a combined acid value of 20. *Peptic digestion* was usually decreased.

A tabulation of these summaries will aid in studying the results:

	Group I.	Group II.	Group III.
QUANTITY RECOVERED.....	32 C.C.	78.7 C.C.	43 C.C.
Free HCl always present.....	4 cases.	6 cases.	1 case.
Free HCl always absent.....	1 case.	3 cases.	2 cases.
Free HCl sometimes absent.....	5 cases.	1 case.	2 cases.
Free HCl doubtful.....	0	1 case.	0
Free HCl (quantitative), average.....	30.3	15.0	18.0
Total acidity, average.....	39.6	32.5	33.0
CHEMICAL CONDITION:			
Normal.....	1	3	0
Hyperacidity.....	1	0	1
Hypocidity.....	2	3	1
Anachlorhydria.....	1	3	2
Variable.....	5d'tful=1		1

Peptic digestion weak in all the groups, as a whole, though normal in some instances.

An examination of the tables and summaries will show that the motor power is little disturbed. The acidity in the first group appears about normal, but in the other groups is markedly decreased. In a large proportion of all the cases the same individual shows, at different times, hypochlorhydria and anachlorhydria. In such cases, I cannot trace any connection with the fever; indeed, in view of Hildebrand's view that free hydrochloric acid was not present at temperatures above 37.8° C., it is of interest to note in several instances that, not only was free hydrochloric acid present with temperatures above this point, but that it was present in normal or increased amounts.

Cornet (21) has suggested that the disturbances are due to pressure on vagus fibres, by swollen gastric glands, and points out the resemblance of these dyspepsias to anorexia nervosa. Some, like Hildebrand, connect it with the fever; others with the anæmia or cachexia. Neither of these causes explains the pretuberculous and initial dyspepsias, as the dyspepsias often precede their occurrence (Cornet). Circulatory changes have been observed in the gastric mucosa, and in late stages

amyloid change has been recorded. In this connection the observation quoted above (Chelmonski, page 9) concerning the absence of free hydrochloric acid in cases of emphysema with complications, is of especial interest, for as he suggests the portal circulation would be altered, secondary to the pulmonary disturbance, thus changing the blood supply of the stomach. Some look upon the sputum swallowed by these patients as an irritant to the mucous membrane, and it is also said that the admixture of sputum will change the reaction of the stomach contents; however, the quantity of sputum must be very large or the acidity of the contents very small, for such a change. Some regard these dyspepsias as specific. From this point of view, the theory that the dyspepsias are due to substances circulating in the blood would appear rational. Others, however, believe the dyspepsias and the tuberculous process to be distinct and their coexistence a mere accident; an accident which seems exceedingly common. One may assume in cases where previous dyspepsias can be eliminated, that the digestive disturbances which introduce or accompany the tuberculous process are manifestations of the reaction of the system to toxic products; a reaction analogous, perhaps, to the rise of temperature following the administration of tuberculin. No other assumption appears to me to explain the pretuberculous and initial dyspepsias, occurring as they do before anæmia, fever, or cachexia, have come on, and often before physical signs can be made out; indeed, before the patient has any pulmonary symptoms whatever.

I cannot agree with Fenwick that the examination of the stomach contents of consumptives is without clinical value. If we can improve the condition of patients suffering from ordinary stomach disease, should not the consumptive have the benefit of treatment in this direction, especially as the main issue in the struggle against his disease is improvement of nutrition?

With or without digestion symptoms, the digestive processes must be studied; the mouth and teeth must be examined, and thorough mastication insisted on; the condition of the stomach must be studied, and the indications thus obtained carefully followed; lastly, the feces should be examined to ascertain if digestion is complete. These investigations, consciously carried out, will enable the physician to prescribe a diet suited to the patient. While it may be urged that an increase in weight is sufficient evidence of his improvement, we must remember that intestinal digestion may compensate for lowered stomach function, so that digestion is apparently perfect.

Again, while most of the food may be utilized some may be excreted in the feces undigested, a condition which will sooner or later lead to trouble. Gain in weight may take place in spite of such conditions, but only careful examination of the digestive tract will enable the physician to bring about the highest efficiency of digestion.

In conclusion, I would say that the number of cases reported is too small for the purpose of generalizing as to the condition of the stomach in pulmonary tuberculosis. The small amount of hyperacidity in my series, its occurrence in the third as well as in the first group, the marked tendency to hypoacidity, and its frequent transformation into anachlorhydria, and the undisturbed motor power, make up the picture presented by these cases.

A CASE OF ACUTE TURPENTINE POISONING.

By GUSTAVE HAUSSER, M. D.,

CINCINNATI.

J. M., aged 37 years, upon the advice of friends, to rid himself of a tape worm, took the ordinary spirits of turpentine. Not knowing the dose, however, he took one tablespoonful of turpentine with an equal quantity of castor oil, every three hours, taking in all from four to five ounces in one day. He then was attacked with severe pains in the abdomen and frequent stools of a bright red character. He became alarmed and the next morning sent for medical advice.

I found him walking around, but stupid, dizzy, and with an unsteady gait, face flushed, and pupils widely dilated. Pulse 82 and of full tension. Temperature 98° F. Abdomen painful and extremely tender on pressure. During the night he passed a clot of blood about the size of an ordinary fist; otherwise stools had the appearance and consistency of blood.

Micturition was frequent and painful, the urine having the characteristic violet odor; also was of a bright red color, and upon examination was found to be loaded with albumin, while microscopically large amounts of red and white corpuscles, bloody, hyaline, and granular casts together with renal epithelium, were found.

Patient was put to bed, ordered large quantities of flax seed tea, together with enemata of same, twice daily; with milk, barley water, and egg nogg for nourishment.

The next day he developed very painful and frequent urination, together with a great amount of tenderness over the suprapubic region; microscopical examination of the urine showed a marked cystitis, which rapidly cleared in a few days, under treatment with tincture of belladonna and potassium acetate.

Red blood cells, renal and bladder epithelium, together with a large amount of albumin occurred in the urine for several days, but by the fourteenth day, and under the treatment with Basham's mixture, all traces of albumin disappeared, and since then he has been apparently none the worse for his experience.

The tape worm was passed in segments before I saw him, but evidently was not completely removed, recurring a few weeks later in large segments. A dose of pelletierine tannate was then prescribed, and a worm some twenty feet in length passed. As some segments from the ends were not brought to me, I failed to find the head, but after ten months no recurrence of the worm has taken place.

2909 VINE STREET.

Tuberculosis Hospital for Milwaukee.—Plans for the establishment of a special sanatorium in Milwaukee county for the care of consumptives are now in the hands of the tuberculosis commission of the Medical Society of Milwaukee County, and it is believed that such an institution will be established within a year. The commission al-

Therapeutical Notes.

NOTES ON THE NEWER MATERIA MEDICA.

Adrenalon, which must not be confounded with adrenalin, is produced by the oxidation of tribenzosulphoadrenalin. It can also be produced synthetically by reacting upon chloracetylpyrocatechin with methylamin. It is credited with special properties in raising the blood pressure.

Agniadin is the name of a glucoside which has been recently introduced into medicine as a remedy for intermittent fever in doses of 2 to 4 grains. It is said to be identical with plumiariid.

Akaralgia is a new granular effervescent salt which is asserted to be especially efficacious in the treatment of migraine, particularly that of the chronic type. According to the makers, it is a combination of sodium sulphate, sodium salicylate (from wintergreen), magnesium sulphate, lithium benzoate, and tincture of nux vomica.

Almatein is an iodoform substitute which is stated to be a compound of hæmatoxylin with formaldehyde. It is described as an odorless powder, soluble in alcohol and glycerin.

Ammonium sulpholeate is an ichthyol substitute.

Anæmose milk is described as an iron iodide buttermilk jelly containing 0.15 per cent. of iron iodide. It is proposed as a milk food in the treatment of chlorosis and anæmia.

Anæsthol-Katz is said to be a mixture of acetyl chloride and methyl chloride. (Ethyl chloride is probably meant instead of acetyl chloride.)

Anæsthol-Meyer is said to be a mixture of acetyl (? ethyl) chloride, 17 per cent., and chloroform-ether mixture, 83 per cent. The chloroform-ether mixture consists of ether, 74 parts, and chloroform, 119.5 parts.

Anticarbuncle serum has been recently introduced and used with good results in the treatment of anthrax.

Antichoren is a peptonized mercuric iodochloride, which has been recently recommended for the treatment of syphilis. It is in the form of a dark brown extract-like substance, which is freely soluble in water. It is very poisonous. Dose, 0.01 gramme three or four times a day.

Antidol is the name applied to an antineuralgic and antipyretic compound which consists of a mixture of caffeine, salicylic acid, citric acid, and antipyrin.

Antimarin is a remedy against seasickness, put up in tablet form by a chemical institute in Berlin. Each tablet contains 3 grains of anæsthesin.

Antipyrin collodion, being a 25 per cent. solution of antipyrin in collodion, is said to be a useful styptic application for small cuts, etc.

Antistaphylococcus serum is, as its name indicates, a protective serum against the germ of suppuration, etc., of recent introduction.

Antiscrophulin is understood to contain potassium sulphoguaicolate, potassium iodide, and hæmoglobin. It is said to be useful as a prophylactic and curative in scrofula and tuberculosis.

Antistreptococcus serum is obtained from horses, in the same way as antidiphtheritic serum is, by inoculating the animals with the streptococci of sepsis, peritonitis, and puerperal fever. It is given in doses of 100 c.c., and frequently repeated in puerperal fever.

Apnol is a liquid preparation of periplocin (the glucoside from *Periploca graca*), which is also stated to contain glycerin, sodium iodide, menthol, pyridine, etc. It is employed by inhalations as spray in the treatment of asthmatic affections.

Aqua ferrocalcea "Terlik" is described as a pleasant tasting, easily digestible iron calcium preparation, the other ingredients of which are not made known.

Attritin (sometimes erroneously spelled Attivin) is the name given to a solution used intravenously in the treatment of rheumatic pains. Some doubt exists regarding the actual composition of the preparation, since the author has published two formulas, as follows: (1) Sodium salicylate, 8 grammes; caffeine-sodium salicylate, 2 grammes, and distilled water, enough to make 50 grammes. (2) Sodium salicylate, 8.75 grammes; distilled water, enough to make 50 grammes. Still another formula, and a more rational one pharmaceutically, in our opinion, has been published: Sodium salicylate, 17.5 grammes; caffeine, 2.5 grammes, and distilled water, enough to make 100 grammes. The journal which publishes this formula (*Pharmazeutische Zeitung*, 1905, 20) says that the sterilized solution is put up in small tubes containing 2.25 c.c., while in other publications the dose is stated at 2 grammes.

Babain is a new antipyrin, salicylic acid derivative, the exact composition of which is not stated.

Betalysol is said to correspond to the saponated solution of cresol of the German Pharmacopœia.

Bioplastica "Seron" is a specially prepared solution of lecithin intended for hypodermic use.

Bioplastin is the name given to a nutritive and strengthening preparation of egg yolk, which is said to contain lecithin and iron, and the phosphates of the egg.

Brandsanal, a remedy for burns, consists of a mixture of carbolic acid, 0.01; picric acid, 0.07; distilled water, 10.00, and glycerin, 0.23.

Brominol is a combination of bromine and sesame oil which is recommended in epilepsy, being a similar compound to bromipin.

Bromlecithin, containing 30 per cent. of bromine, is a new preparation of the Aktien-Gesellschaft für Anilinfabrikation, Berlin. It is recommended in the treatment of diseases of the nervous system for which its components find use.

NON-OFFICIAL DRUGS AND THE AMERICAN MEDICAL ASSOCIATION.

Last week we published the rules recently adopted for governing the American Medical Association's Council on Pharmacy and Chemistry as to the admission of medicinal preparations to mention in a book to be published by the association, under the title of *New and Non-Official Remedies*. In these rules the association states more definitely than it has done heretofore its attitude toward the various non-official preparations, and especially toward the proprietary remedies.

The same rules, it is declared, are to govern the admission of advertisements into the advertising columns of the association's *Journal* and mention of the products to which they relate in its reading columns. The rule that is apparently most likely to bring out a divergence of views between the council and the manufacturers reads as follows: "No article will be admitted unless its active medicinal ingredients and the amounts of such ingredients in a given quantity of the article be furnished for publication. (Sufficient information should be supplied to permit the council to verify the statements made regarding the article and to determine its status from time to time.)"

It seems to us that the requirements embodied in this rule, simple as they appear, will be con-

strued by many of the manufacturers as calling for such an exposition of their processes as they will feel themselves unable to furnish without peril to their business. The proportion of manufacturing pharmacists who will be inclined to take this view is probably a large one. But those who decline to conform to the rule will necessarily find their advertisements barred from the *Journal of the American Medical Association*. The financial showing of the association journal is so favorable, however, that any loss of advertising patronage in consequence of the enforcement of the rules can be borne with equanimity. Even were this not the case, there could be no question of recession from the rules without stultifying the council, the journal, and the association.

UNITY OF PURPOSE IN MEDICINE.

Unity in medical organization is an object that has been very diligently and devotedly pursued of late, and we hope that the pursuit is to be crowned with success everywhere before long. But there is another phase of unity that needs to be sought for in the profession, and, under the name of monism, it was recently well set forth by Dr. Abraham Jacobi before the New England Association of Graduates of the Medical Colleges of New York City, whose address is published in the February number of the *Annals of Gynecology and Pædiatry*. It is unity of purpose in medical study.

We should not approach the study of medicine, especially study having for its object the proving or disproving of old doctrines or the setting up of new ones, with the mind possessed by preconceived notions. Such notions hindered us woefully in the past. We have, it is true, emancipated ourselves from thick and thin maintenance of humoralism on the one hand and of solidism on the other, and from many another contest in which triumph was more prized than truth; and not from such contentions only, but from the conviction that they were in the least degree tolerable. It will doubtless long remain true that "doctors disagree," but their disagreements are surely growing less and less radical and more and more temporary. It does not now take so long as it formerly took to establish facts that are opposed

to tradition, and when they are established they are more universally recognized. What Dr. Jacobi spoke of as the medicine peculiar to any one nation or people is constantly assuming smaller dimensions as compared with the medicine that is accepted by the world, but local peculiarities in interpreting observed facts will doubtless for a long time yet obstruct complete unity among those who are laboring to advance the science as a whole. As Dr. Jacobi suggested, the survival of these small differences might perhaps be materially curtailed by imitating the German students in their tendency to go from one university to another during the course of study.

PHAGOCYTOSIS AND OPSONIC ACTION.

There seems to be reason for supposing that in phagocytosis the leucocytes do not play such a preponderating, not to say exclusive, part as has been insisted on by Metchnikoff and others. Some time ago it was shown by Wright and Douglas before the Royal Society that the serum acted upon the bacteria in such a way as to render them an easy prey for the multinuclear leucocytes. Those gentlemen's conclusions have recently been confirmed by Bulloch and Atkin (*Proceedings of the Royal Society*, February 24th).

This preliminary action of the serum is called opsonic, and the substance in the serum that accomplishes it is termed an opsonin. Bulloch and Atkin find that there is an opsonin present in normal serum. It is thermolabile and rapidly disappears when the serum is mixed with bacteria at the normal temperature of the blood or at any temperature below that down to the freezing point of water. The leucocyte is practically an indifferent factor when the phagocytic power of different bloods is compared. The opsonin is of relatively simple constitution, but it is not identical with any of the antibodies previously discovered in serum.

After all, it appears to be the leucocyte that accomplishes the actual phagocytosis, but it may be, for all that, that the opsonic action of the serum is the essential feature in the work of riding the blood of pathogenic bacteria, and that phagocytosis itself is merely a way of disposing of foreign material that has been rendered innoc-

uous. Such investigations as we have referred to, little as they may affect our estimate of the general powers of the blood over pathogenic bacteria, must prove distinctly helpful in leading the way to a final unraveling of the mechanism of immunization.

THE DIAGNOSIS OF PAPILLOMA OF THE BLADDER.

In subjects otherwise healthy, who have never presented bladder symptoms, papilloma of the urinary reservoir will make its presence known by the sudden appearance of blood in the urine, occurring without other conceivable cause. The hæmorrhage, of varying intensity, arises without any prodromes; the amount of blood voided is sometimes only small. The hæmorrhage recurs several times in decreasing quantity and may entirely disappear within three or four days, the patient's health being unaffected. Weeks, months, or even several years may pass before the hæmorrhage again appears or any symptom of vesical neoplasm becomes manifest.

In other instances the bleeding recurs at short intervals or may be continuous. Now, the manner and form of the hæmorrhage are so characteristic that it can easily be distinguished from that arising in other parts of the genitourinary system. When the seat of the hæmorrhage is in the urethra, the loss of a few drops of blood or a long, narrow clot, followed by perfectly clear urine, is quite characteristic, but after micturition one will be able to press out a drop or two of blood from the urethra or it may be voided spontaneously.

When a renal lesion exists, the urine will be uniformly red in color, because there has been an almost perfect blending of the two fluids, but in neoplasms of the bladder the urine is at first not mixed with the blood, or only slightly so, but toward the end of micturition it becomes more and more so, and the last part voided may consist of almost pure blood. Microscopically one may recognize whether the source of the hæmorrhage is the kidney or the bladder. In the former we have the so called shadows of the red corpuscles, while in the latter they show all the evidence of fresh blood.

The amount of bleeding depends on the type of neoplasm; if slender villi compose the growth, bleeding will be more persistent and repeated, because they are easily torn off, while in the fibrous form of papilloma this symptom will be much less marked on account of the coarser structure of the growth. Then, again, the seat of the tumor exercises an influence on the hæmorrhage, because papilloma situated at the urethral orifice is certainly more prone to bleed than when developing in the walls of the bladder, on account of the greater pressure brought to bear on the growth in the former situation during micturition.

Pain is another symptom frequently occurring in papilloma of the bladder, and it may be present at an early stage of the affection. It is dull and steady in the region of the perinæum; tenesmus is frequent, with a severe stinging sensation in the urethra and glans, which is more particularly pronounced when clots or pieces of the growth are passed. Painful erections may also trouble the patient.

If the growth has a long pedicle or is situated near the orifice of the bladder, it may occlude it and oblige the patient to resort to various attitudes in order to overcome the obstruction. Should the neoplasm develop near the ureteral orifices, hydronephrosis in one or both kidneys may develop, leading to serious secondary lesions of the organ, and death has been known to take place from uræmia.

A fairly common complication of papilloma is cystitis, which may arise spontaneously or result from instrumental interference; it is often chronic, producing a necrobiotic change in the growth, and may extend to the kidney.

Bits of the tumor passed with the urine are of essential importance for diagnosis, for they allow one to conclude with certainty that a tumor exists, but they do not always throw much light on the nature of the neoplasm, because in many cases microscopical examination cannot distinguish between papilloma and carcinoma. The reason is this, that there are to be found in the midst of the tissue spaces filled with epithelium. They are usually narrow alveoli and thickly filled with polymorphous epithelium, which at first sight

gives one the impression of carcinomatous alveoli, but close examination will show the error. In larger sections, including the entire growth, it at once becomes evident that these alveoli are simply transverse sections of the fissures existing between the villi, and this consequently accounts for the mistakes arising in the examination of particles voided in the urine, for here the tips of the villi, and rarely the base of the neoplasm, are obtained.

From the presence of the above named symptoms one can naturally diagnose a tumor of the bladder, but when hæmaturia, often of a temporary kind, exists without any other symptom, the nature of the case is more difficult to recognize. Palpation is usually negative, especially when the growth is a small, soft, villous polypus, but irrigation of the bladder may detach some villi. The sound is of little value, because these soft, velvety growths cannot be detected by it, and serious hæmorrhage and infection of the bladder may ensue from its use.

Cystoscopy is a most valuable diagnostic means, for with it one can detect a bladder neoplasm in its early stages, as well as its exact site. Now, without wishing to underestimate the value of the cystoscope, we must confess that it cannot be relied upon, in cases of papillomata, because that part of the trigonum near the urethral orifice, which is a frequent site for papilloma, is not readily accessible to the instrument. And, what is more, a good picture cannot be obtained, on account of the bleeding to which these growths give rise, even after the bladder has been repeatedly washed out and when a modern instrument with irrigating attachment is employed.

If cystoscopy fails or cannot be resorted to for any reason, suprapubic cystotomy should be done for diagnosis, and since operative treatment can be carried out at the same time, this procedure is quite justified. Dilatation of the urethra in the female and digital exploration of the bladder can be resorted to, but, as I have elsewhere pointed out, this method should be condemned unless carried out with the utmost care, on account of permanent incontinence to which it may give rise.

CHARLES GREENE CUMSTON.

ELEVATED RAILWAYS IN THE CONGESTED DISTRICTS OF THE POOR.

There is grave danger, that a plan may be adopted by the Rapid Transit Commission to run an elevated railway through the entire length of Delancey Street, down Baxter Street, and adjoining Mulberry Bend Park. The physician who practises among the poor in the congested districts of the east side, or even in tenement houses along Ninth, Sixth, Third, and Second Avenues, which are relatively wide, will know, from experience, what the noise of passing trains every minute or so means to his patients. It racks the nerves by day and robs of sleep by night. The other day I was called in consultation to see a young woman living on a fourth floor on Columbus Avenue, the height exactly corresponding to the track of the elevated railway. It was a task to make a physical examination, so constant was the noise. The poor woman assured me that, although she had lived in that flat for a number of years and become accustomed to the noise, since she had been taken ill she had hardly had one night's sound sleep. The rolling by of the trains, in her opinion, had not a little to do with the aggravation of her disease. The rooms this woman occupied were light, owing to the width of the street, and well ventilated. Her removal to a neighboring sanatorium gave her the long prayed for undisturbed sleep the very first night, without the use of any hypnotic.

The conditions which are produced by an elevated railway structure, situated as it is in Allen Street, on the east side, are of course many times worse than those described on Columbus Avenue. There the noise, owing to the narrowness of the street and the relatively low level of the elevated structure, is greatly increased. As the houses are also low, the elevated road in Allen Street darkens nearly all the flats and makes the entrance of sunlight into any of the crowded rooms of that congested district impossible. That the sanitary conditions in these houses must be terrible is evident.

The City Club, which has investigated this matter thoroughly, recently issued a circular wherein it is very pertinently pointed out that, both from a sanitary and from a social and moral point of view, such conditions as exist in Allen Street

should not be repeated in any other portion of the congested east side. The circular referred to says that the construction of an elevated road, such as is proposed, will be little short of criminal, and unless the influential members of the community make manifest to the Rapid Transit Commission in the strongest possible way their opposition to this plan, there is grave danger of its being adopted. I do not believe that any members of the community can be more influential in this matter than the physicians. We should make our influence felt in this matter by the strongest possible protest. Resolutions should be passed by the Academy of Medicine and other medical societies condemning any plan to run elevated railways throughout Delancey Street, Baxter Street, or any other portion of the congested eastern districts. The Committee on the Prevention of Tuberculosis has already passed resolutions opposing the above mentioned plan of a new elevated railway.

In our combat against diseases due to the lack of light and air, and the numerous nervous affections caused by our fearful city noises, we should begin by protesting against any measure which will propagate such diseases. The physician of the poor cannot send all his patients away to sanatoria; there are not enough of such institutions; many patients, and even consumptives, must be treated at home. This treatment at home is possible in a fairly good tenement house; it is utterly impossible in homes facing dark and noisy streets.

Besides the above recommended resolutions on the part of medical societies, I am convinced that individual protests on the part of medical members of this community, addressed to Mr. Alexander E. Orr, president of the Rapid Transit Commission; the Honorable George B. McClellan, mayor of the city of New York; the Honorable Edward M. Grout, comptroller, or any other member of the Rapid Transit Commission, will also greatly help to make the adoption of the above mentioned elevated railway plan impossible. S. A. KNOPP.

A WORTHY UNDERTAKING BY THE ROCKEFELLER INSTITUTE.

The *Journal of Experimental Medicine*, which for several years has been one of the ablest exponents

of scientific medicine, has recently come under the editorial management of Dr. Simon Flexner and Dr. Eugene L. Opie, and is henceforth to be published under the auspices of the Rockefeller Institute for Medical Research. The institute could not have undertaken a more praiseworthy work.

A PROPOSED "REFORM" OF THE ROGUES' GALLERY.

Apropos of the hardship to innocent persons arising from their photographs being retained in the rogues' gallery, the *New York Times* proposes, with apparent seriousness, the remedy of procuring the likenesses and Bertillon measurements of the public in general. The collection thus formed, it says, would "serve many and important services," whatever that may mean, and it adds that the present appreciation of "vital statistics" is so high that it ought not to be impossible to induce people indiscriminately to submit to the camera and the measurements. We fancy we can see the populace thronging police headquarters for the purpose!

SYPHILITIC MENINGOENCEPHALITIS.

In a case reported by P. M. Sniker, of St. Petersburg (*Archiv. für Dermatologie und Syphilis*, lxx, 3; *Berliner klinische Wochenschrift*, January 23rd), it is noteworthy that the syphilis, which was of seven years' standing, had resisted 200 mercurial inunctions, 250 injections of mercury, and 200 bottles (size not given) of potassium iodide. The lesions affected chiefly the meninges and cortex of the right central convolutions, and the pronounced symptoms were Jacksonian epilepsy and total loss of the stereognostic sense.

NO MORE ELEVATED RAILWAYS.

Not only do we heartily join Dr. Knopf, whose "signed editorial" appears in this issue, in calling upon the physicians of New York to oppose the building of an elevated railway in Delancey Street, but, seconding the efforts of Dr. Girdner, we protest in the name of the sick and the overwrought against the establishment of any more such structures in New York. Let us henceforth build our urban railways under ground, and cease to add to the sleep-destroying agencies of the metropolis.

The Union of Old German University Students.—The Vereinigung alter deutscher Studenten in Amerika will hold its anniversary Commers on Saturday evening, March 25th, in Arion Hall, New York, under the presidency of Dr. Carl Beck.

News Items.

Society Meetings for the Coming Week:

MONDAY, March 20th.—New York Academy of Medicine (Section in Ophthalmology); New York County Medical Association; Hartford, Conn., Medical Society; Chicago Medical Society.

TUESDAY, March 21st.—New York Academy of Medicine (Section in General Medicine); Buffalo Academy of Medicine (Section in Pathology); Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Medical Society of the County of Kings, N. Y.; Baltimore Academy of Medicine.

WEDNESDAY, March 22nd.—New York Academy of Medicine (Section in Laryngology and Rhinology); New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Philadelphia County Medical Society; New York Dermatological Society (private).

THURSDAY, March 23rd.—New York Academy of Medicine (Section in Obstetrics and Gynecology); New York Orthopaedic Society; New York Celtic Medical Society; Brooklyn Pathological Society; Brooklyn Society for Neurology; Roxbury, Mass., Society for Medical Improvement (private); Pathological Society of Philadelphia; Church Hill Medical Society of Richmond, Va.

FRIDAY, March 24th.—New York Clinical Society (private); New York Society of German Physicians; Yorkville Medical Association, New York (private); Philadelphia Clinical Society; Philadelphia Laryngological Society.

SATURDAY, March 25th.—New York Medical and Surgical Society (private); Harvard Medical Society, New York (private).

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending March 11, 1905:

	March 11.		March 4.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	349	10	252	6
Diphtheria and croup.....	296	26	276	30
Scarlet fever.....	270	19	248	22
Smallpox	1	3	3	..
Chickenpox	159	..	98	..
Tuberculosis	480	183	390	188
Typhoid fever.....	30	9	42	10
Cerebrospinal meningitis.....	..	76	..	60
	1,585	323	1,309	316

The **Medicolegal Society** of New York held a joint session with the **Physiological Society** at the Waldorf-Astoria on March 15th.

Cerebrospinal Meningitis.—There were 58 deaths from cerebrospinal meningitis in New York city for the week ending March 11th, an increase of nine over the previous week. The disease is also prevalent in many parts of Connecticut.

Orthopaedic Hospital.—Two concerts for the benefit of the New York Orthopaedic Hospital were given in Carnegie Hall, March 13th and 14th. Those appearing included Ysaye and Kreisler, violinists; the New York Symphony Orchestra, and Walter Damrosch. Over \$10,000 is said to have been raised.

Unlicensed Practitioner Imprisoned.—James M. Solomon, who claims a home in Brookline, Mass., was found guilty on March 13th of practising medicine in New York without a license and ordered committed to the toms for thirty days and fined \$500, or to serve one day additional for each dollar not paid.

A Conference on Hospital Needs and Finances will be held in the United Charities Building on March 23rd, and the New York hospitals and charitable organizations having daily contact with illness and injury will have representatives present. The object of the meeting is to devise some means for the prevention of the deficit in the income of the private hospitals, which causes a curtailment of many lines of hospital activity. After a discussion of the matter by hospital directors, superintendents, medical advisers, and supporters, it is the intention to secure the appointment of a committee, composed of representative persons, which shall frame a practical scheme of improvement and make arrangements for carrying their ideas out.

New York State Medical Association, New York County.—A stated meeting of this body will be held on Monday, March 20th, at 8.30 p. m., with the following programme: Executive session; scientific session: Presentation of clinical cases or reports, pathological specimens, new instruments, etc.; papers: A Plea for Local Anæsthesia in the Radical Cure of Inguinal Hernia, a study based on 300 cases, by Dr. John A. Bodine; discussion opened by Dr. Harvey Cushing, of Baltimore, Md., followed by Dr. W. L. Rodman, of Philadelphia, Pa., Dr. George E. Brewer, Dr. R. H. M. Dawbarn, Dr. Robert T. Morris, and Dr. W. B. Coley; The Administrative Control of Tuberculosis, by Dr. Hermann M. Biggs; discussion by Dr. John Winters Brannan, Dr. Egbert Le Fevre, Dr. Thomas Darlington, and others. William Ridgely Stone, M. D., secretary.

The Society of Medical Jurisprudence held its twenty-third annual dinner on March 11th at the Hotel Astor, Manhattan, and was attended by about 150 members of the medical and legal professions. Professor Carl Beck acted as toastmaster. The speakers and their subjects follow: The Importance of a Thorough Medical Education, by D. B. St. John Roosa, M. D., LL. D.; Pure Food and the Law, by Justice Almet F. Jenks, LL. D., Appellate Division, Second Department; A Pulpit View of Physicians and Lawyers, by the Reverend Thomas S. Slicer, D. D.; Politics and Ethical Law, by Congressman William Sulzer; Doctors and Lawyers as Citizens, by Frank P. Foster, M. D.; The Insanity Plea Again, by John S. Wise; The Friendly Art of Lying, by C. F. Moore; Woman—the Old and the New, by Timothy Goodfriend.

Medical Inspectors' Society Organized.—A society for study, the promotion of good fellowship, and the discussion of problems in hygiene and public health was organized recently by the medical inspectors of the health department of the city of New York, under the name of the Society of Medical Inspectors of the City of New York, and medical inspectors of any of the divisions of the health department, in any of the boroughs, are eligible to membership. The organization of the society was completed by the adoption of a constitution and the election of officers at a meeting held at the Academy of Medicine on the evening of March 3, 1905. Dr. Edward M.

Thompson, the chairman of the committee on organization, presided, and in his address to the assembled inspectors referred to the fact that this was the first meeting of its kind, he believed, ever held in this city. The society purposes to hold monthly meetings at which scientific papers relating to hygiene and sanitation will be read and discussed. The higher officers of the department and other sanitarians of note will be asked to address the society at the different meetings on topics of special interest. The programme of the society also includes a number of social features, such as an annual dinner, etc. The following officers were elected for the first year: President, Dr. Augustine C. McGuire; vice-president, Dr. Otto Jahn; secretary, Dr. Edward M. Thompson; treasurer, Dr. Leopold Marcus; executive committee, Dr. Joseph Baum (chairman), Dr. Helen Knight, Dr. Samuel A. Buchenholz, Dr. Thomas M. Neasey, and Dr. DeSantos Saxe.

Academy of Medicine.—The section in ophthalmology will meet on Monday, March 20th, at 8.15 p. m. Order: Presentation of Patients; Case of Extirpation of the Lacrymal Sac; Plastic Operation for Formation of Cul de Sac for Wearing of an Artificial Eye, by Dr. D. W. Hunter; Case of Pearl Cyst of the Iris, by Dr. Robert G. Reese; Removal of a Large Endotheliocylindroma from the Orbit, with Preservation of the Vision and Motility of the Eye, by Dr. J. E. Weeks; Extraction of Lens Dislocated Into the Anterior Chamber, with Secondary Glaucoma, by Dr. W. B. Marple; Case of Annular Scleritis, Congenital Glaucoma, with Deaf Mutism, by Dr. C. W. Cutler; Presentation of New Instruments: Scissors for Cutting Secondary Membranous Cataracts, by Dr. E. L. Oatman; Cysts of the Pars Iridica Retinae, with Report of a Case, by Dr. E. L. Oatman; paper: Unilateral and Other Unusual Forms of Nystagmus, by Dr. Alexander Duane; paper: The Advantages of Transillumination, with Demonstration of the Sachs Lamp, by Dr. E. S. Thomson. Wilbur B. Marple, M. D.; chairman; Herbert W. Wootton, M. D., secretary, 35 West Forty-fifth Street.

The section in medicine will meet on Tuesday, March 21st, at 8.15 p. m. Order: Annual Election of Officers; Presentation of Cases; Clinical Reports: A Case of Acute Polyarticular Gout, by Dr. M. B. Potter; A Sterile Purulent Joint, following Acute Articular Rheumatism, by Dr. H. S. Carter; papers: The Present Clinical and Bacteriological Status of Vincent's Angina, by Dr. W. N. Berkeley; discussion by Dr. Mayer, Dr. Thacher, Dr. Simpson, Dr. Lipman, Dr. Sobel, Dr. Bell, and others; Recent Studies in the Diagnosis of Rabies, by Dr. B. W. Poor; discussion by Dr. Biggs, Dr. Dulles, Dr. Ewing, Dr. Park, Dr. Brooks, Dr. Huddleston, Dr. Wilson, Dr. Bailey, and others. Charles H. Lewis, M. D., chairman; E. E. Smith, M. D., secretary, 26 East Twenty-ninth Street.

The section in obstetrics and gynecology will meet on Thursday, March 23rd, at 8.15 p. m. Order: Presentation of Specimens: (a) Adenocarcinoma of Uterus; (b) Essential Metrorrhagia; Hysterectomy; (c) Displaced Pyonephrotic Kid-

ney; Nephrectomy, by Dr. Arnold Sturmdorf; paper: Morbid Processes in the Right Abdominal and Pelvic Regions of the Female, and Their Differentiation, by Dr. J. A. Schmitt; discussion by Dr. Brooks H. Wells, Dr. Robert T. Morris, Dr. E. H. Grandin, Dr. George E. Brewer, and others. Charles F. Adams, M. D., chairman; Arnold Sturmdorf, M. D., secretary, 51 West Seventy-fourth Street.

PHILADELPHIA.

Proposed Food Law Vetoed.—On March 9th Governor Pennypacker vetoed a bill "to prohibit the adulteration of food and providing for the enforcement thereof." In the midst of a long section of the bill the following words occur: "But the use of such added substances in such proportions or less shall be and is hereby permitted." This refers to 0.25 per cent. of sodium benzoate or added color. As no reference was made to this important provision in the title of the act the instrument was unconstitutional, and therefore vetoed.

Scientific Society Meetings for the Week Ending March 25, 1905.—Monday, March 20th, Society of Normal and Pathological Physiology, University of Pennsylvania. Tuesday, March 21st, Section on Ophthalmology, College of Physicians; Dermatological Society; Academy of Natural Sciences. Wednesday, March 22nd, Philadelphia County Medical Society. Thursday, March 23rd, Pathological Society; Entomological Section, Academy of Natural Sciences. Friday, March 24th, South Branch, Philadelphia County Medical Society; Northern Medical Association; American Society of Tropical Medicine, business meeting at 8 p. m. for members, scientific meeting at 8.30, to which all physicians are invited.

Changes in the Staff of the Philadelphia General Hospital.—The following appointments have been made at the Philadelphia General Hospital: Dr. Joseph Sailer, visiting physician; Dr. William Pickett and Dr. D. J. McCarthy, visiting neurologists; Dr. J. H. McKee, visiting pediatricist; Dr. Hilary M. Christian, Dr. E. Hollingsworth Siter, and Dr. Henry Tucker, visiting genitourinary surgeons; Dr. G. Paul La Roque, assistant surgeon; Dr. C. Y. White, Dr. John W. Hunter, and Dr. George Norris, assistant physicians; Dr. Charles C. Norris, assistant obstetrician; Dr. Samuel McClarg, assistant neurologist; Dr. Howard Childs Carpenter, assistant pediatricist; Dr. Charles A. Hatfield, Dr. T. Y. Ullom, Dr. J. W. Irwine, and Dr. J. Hamilton Small, assistant physicians, department for tuberculosis; Dr. Macy Brooks, Dr. Alexander Uhle, and Dr. Howard Dahoney, assistant genitourinary surgeons; Dr. H. R. Alburger, assistant anæsthetist; Dr. Thomas B. Holloway and Dr. Ward Brinton, registrars.

The State Veterinary Medical Association met in Philadelphia on March 8th and 9th. Dr. Clarence J. Marshall made an appeal for the support of the bill now before the Legislature to appropriate \$100,000 for purposes of a building for the

veterinary department of the University of Pennsylvania. Dr. D. H. Bergey read a paper on the inflammatory conditions of cows' udders. Dr. Leonard Pearson announced that a method of vaccinating cattle against tuberculosis had been carried out successfully by the State Live Stock Sanitary Board. Dr. Pearson advanced the theory that milk of highly vaccinated cows may contain an antitoxine which will halt tuberculosis in human beings. The following officers were elected: President, Otto G. Noack, of Reading; vice-presidents, Thomas B. Rayner, of Chestnut Hill; J. B. Irons, of Erie; H. S. Jackson, of Allegheny County; treasurer, Francis Bridge, of Philadelphia; recording secretary, B. T. Woodward, of Oxford; corresponding secretary, C. J. Marshall, of Philadelphia.

Medical Society Programmes.—The following was the programme of the Philadelphia County Medical Society at its meeting held March 8th:

Dr. Charles W. Burr, Exhibition of a Patient with an Old Fracture of the Cervical Spine; Dr. J. Madison Taylor, How Can the General Practitioner Profit by Preventive Medicine; Dr. W. G. B. Harland, The Problem of the Treatment of Tuberculosis of the Larynx; Dr. W. Wayne Babcock, The Osmic Acid Treatment of Tic Douloureux.

The following was the programme of the meeting of the Society of Normal and Pathological Physiology, held March 6th:

Observations Upon the Blood Pressure of Intracranial Conditions, by Dr. Charles H. Frazier; Discussion Upon the Clinical Data Obtained from Estimations of Blood Pressure, by Dr. Alfred Stengel; Demonstration of Apparatus for Determining Blood Pressure in Man, by Dr. W. B. Stanton; The Use of the Sphygmomanometer in Therapeutics, by Dr. H. C. Wood, Jr.; Some Experimental Observations Upon the Lower Animals to Determine the Accuracy of Stanton's Apparatus in Recording the Maximum and Minimum Blood Pressure, by Dr. D. M. Hoyt.

At a meeting of the Northern Medical Association, held March 10th, Dr. Samuel Wolfe read a paper on Abdominal Pus Collections. The discussion was opened by Dr. Wilmer Krusen.

The Health of the City.—The following cases of transmissible diseases were reported to the bureau of health for the week ending March 4, 1905:

	Cases.	Deaths.
Typhoid fever.....	92	11
Scarlet fever.....	46	1
Cholera.....	67	0
Diphtheria.....	48	7
Cerebrospinal meningitis.....	3	1
Measles.....	18	0
Whooping cough.....	11	2
Tuberculosis of the lungs.....	17	12
Pneumonia.....	74	72
Erysipelas.....	12	6
Puerperal fever.....	1	1

The total deaths for the week numbered 559, in an estimated population of 1,438,318, corresponding to an annual death rate of 20.21 per 1,000 population. The total infant mortality was 112; under one year, 97; between one and two years, 15. There were 38 still births; 19 males and 19 females. The following deaths were reported from other transmissible diseases: Malarial fever, 1; tuberculosis, other than tuberculosis of the lungs, 8; tetanus, 1; dysentery, 2; diarrhoea and enteritis under two years, 16. The weather was mild, with a rain precipitation of 0.39 inch.

Tuberculosis.—The Philadelphia Board of Health has issued the following circular letter to the physicians of that city:

MY DEAR DOCTOR:

A number of communications received from physicians in the city relative to the reporting of tuberculosis lead me to suspect that there is more or less misunderstanding on the subject, and I take this occasion to inform you of the board's attitude towards cases of tuberculosis that are reported.

Cases of tuberculosis are not regarded in the same light as are those of the acute transmissible diseases. They are not, therefore, subjected to the same official supervision. Nevertheless, for the protection of the public health, it is essential that cases of tuberculosis be kept under sanitary supervision. For the information of the board upon this matter you are requested to fill out the enclosed blank and forward it to this office. If it is not entirely convenient for you to fill out this blank, or if for other reasons you prefer to have it done by one of our representatives, kindly notify me and I will detail a man for the purpose. If I do not get a reply to this communication I will take it that you prefer to have us gather the data.

The names and addresses of cases of tuberculosis reported to this office are matters of official record, and will under no circumstances, be made public.

Whenever the bureau desires special information concerning particular cases, the request is made to the attending physician and not to the patient, except in the case of destitute persons who may not be under a physician's care.

The board carefully refrains from doing anything to alarm patients whose names have been reported.

The board recommends that all rooms occupied by tuberculous patients be periodically disinfected during the course of the disease and again after the rooms and house have been vacated. The disinfection is not done on the board's initiative, but only after the attending physician has been consulted and the consent of the patient or the relatives is given. In notoriously unsanitary premises, and in the case of persons who are unwilling or unable to take the necessary precautions, the board reserves the right to subject these premises and persons to such sanitary regulations as may be deemed appropriate.

From the foregoing it is obvious that tuberculous cases reported to the board are subjected to neither hardships nor official supervision, other than that necessary to protect the public health, and that there is, therefore, no good reason for failure to regularly report them.

Very truly yours,

A. C. ABBOTT, M. D.,
Chief of bureau.

GENERAL.

The Children's Free Hospital, of Youngstown, Ohio, has recently received gifts to the extent of \$1,500.

Proposed Insane Asylum for New Hampshire.

A bill is before the New Hampshire legislature for the appropriation of \$200,000 for a new insane hospital at Concord.

Jersey City Hospital.—Dr. Charles A. Limeburner has resigned from the medical staff of the Jersey City Hospital. Owing to recent withdrawals the institution is left with but three attending physicians.

Grand Medical Examiner of the A. O. U. W.—Dr. A. H. Briggs, of Buffalo, has been reappointed grand medical examiner of the A. O. U. W., making the twenty-fifth consecutive term of the physician in this office. The appointment was made in Syracuse on March 9th.

Memphis and Shelby County, Tenn., Medical Society.—The annual election of officers of the Memphis and Shelby County Medical Society was held on March 8th with the following result: Dr. J. L. Andrews was elected president for the current year, Dr. J. L. Barton was chosen vice-president, and Dr. Cummings Harris, secretary.

Austin Flint Medical Society of Pittsburgh.—The thirteenth annual banquet of the Austin Flint Medical Society was held on February 28th at the Colonial Hotel, Pittsburgh. The officers who were recently elected are: President, Dr. Walden A. Clark; vice-president, Dr. Frank Kenworthy; secretary treasurer, Dr. Robert E. Davidson; board of directors, Dr. S. H. McKibbey, Dr. A. L. Lewin, and Dr. Kenworthy. Dr. J. C. Dunn acted as toastmaster.

Frederick City, Md., Hospital.—A large addition to the Frederick City Hospital, donated by Mrs. Margaret Scholl Hood, and to be known as the Hood wing, was formally opened on March 8th. Governor Warfield was present and made an address. The wing, which practically doubles the capacity of the hospital, cost about \$10,000. It contains numerous private rooms, a large sun parlor, etc. All of the rooms have been furnished by friends of the hospital.

Medical Harmony in Montreal, Canada.—It is alleged that in the past there has been some little friction between the English and French speaking physicians of the Canadian metropolis. It appears, however, that all differences have been harmonized, and at a banquet given at the Windsor Hotel on February 21st, the members of the Société medicale de Montréal and the Montreal Medico-Chirurgical Society, the most prominent members of each organization spoke hopefully of perfect accord in the future.

Graduate Nurses from Mercy Sanitarium, Denver.—The following twelve nurses graduated recently at the nurses' training school of the Mercy Sanitarium: Adelaide James, of Kansas City, Kan.; Elizabeth Gray, of Coldwater, Mich.; Carolyne Croutwick, of Giltner, Neb.; Anna Kelliher, of Kansas City, Kan.; May Firedaugh, of Durango, Colo.; Pearl Dunlap, of Telluride, Colo.; Mary Fahey, of West Court, Ireland; Cecile Young, of New Orleans, La.; and four sisters, Sister Mary John, Mary Stanislaus, Mary Anthony, Mary de Sales.

Herkimer County, N. Y., Medical Society.—The Herkimer County Medical Society held its annual meeting and banquet March 7th at the State army in Mohawk. The following officers were elected for the ensuing year: President, Dr. U. G. Williams, of Newport; first vice-president, Dr. A. C. Douglas, of Ilion; second vice-president, Dr. Ellis, of Little Falls; third vice-president, Dr. Brainerd, of Little Falls; secretary, Dr. A. Walter Suiter, of Herkimer; treasurer, Dr. George Graves, of Herkimer.

Wyoming State Board of Medical Examiners.—The newly appointed State board of medical examiners has just held its first meeting at Cheyenne, electing Dr. E. P. Rohrbaugh, of Casper, as president; Dr. Oliver Chamber, of Rock Springs, vice-president; Dr. S. B. Miller, of Laramie, secretary. The board decided to rigidly enforce the law passed by the last legislature, which, in effect, prohibits the practice of osteopathy and Christian Science in Wyoming. A large number of osteopaths and science healers, now operating in the State, will be compelled to leave or submit to prosecution under the law.

Graduate Nurses of Grace Hospital, Detroit.—The following nurses have graduated from this institution: Jessie C. Smith, of Dowagiac; Mary E. Schaft, of Oakland; Helen R. Bock, of Detroit; Mary Proudfitt Langley, of Saginaw; Mary Cook, of St. Thomas, Ont.; Edith M. Naylor, of Essex, Ont.; Gertrude Ada Peel, of Toronto; Anna Maria Schill, of Saline; M. Alba Ransom, of Blenheim, Ont.; Anna McCormick, of Windsor; Helen Darling Humphreys, of Sidney, O.; Edith Winnifred Lawson, of Stratford, Ont.; Mildred M. Palmer, of Cleveland; Rachel Joliffe Mulheron, of Detroit; Arthur B. Henderson, of Detroit; James Earl Hamilton, of Amherstburg, Ont.

Chicago Neurological Society.—A meeting of this society was held at the Sherman House, Thursday, March 16th, at 6.30 p. m. Dr. Sydney Kuh presented a case for diagnosis; Dr. L. H. Mettler presented a case of syphilitic spastic paraplegia (Erb's type) and a case of the less common type of tabes dorsalis; Dr. Alfred C. Croftan related some studies of epilepsy of gastrointestinal origin; Dr. Harold N. Moyer showed a case of Raynaud's disease with new suggestions as to treatment; Dr. Peter Bassoe described his studies upon cerebral softening, including histories and specimens. L. Harrison Mettler, M. D., secretary and treasurer.

Mortality of Michigan During February, 1905.—The total number of deaths returned to the department of State for the month of February was 3,218, corresponding to a death rate of 16.4 per 1,000 population. This is higher than the rate for the preceding month, 14.2 per 1,000, but slightly lower than the death rate for February, 1904, which was 17.1 per 1,000. By ages there were 629 deaths of infants under one year of age, 165 deaths of children aged one to four years, and 1,089 deaths of elderly persons over 65 years. There is increased mortality at the extremes of life as compared with the preceding month. Im-

portant causes of death are as follows: Tuberculosis of lungs, 191; other forms of tuberculosis, 35; typhoid fever, 46; diphtheria and croup, 27; scarlet fever, 10; measles, 7; whooping cough, 4; pneumonia, 442; diarrhoeal diseases, under two years, 61; meningitis, 59; influenza, 184; cancer, 106; accidents and violence, 158. There was a slight increase in the mortality from typhoid fever and considerable increase in that from pneumonia, meningitis, and influenza. Diphtheria and croup caused fewer deaths than usual. The largest number of deaths from smallpox of any month since registration began under the present law occurred—namely, 11, distributed as follows: One in Standish township, Arenac county; two in Blackman township, one in summit township, and five in the city of Jackson, Jackson county; two in Perry village, Shiawassee county.

Statement of Mortality in Chicago for the Week Ending March 11, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on Census Bureau's figures of estimated midyear populations of 1,990,750 for 1905 and of 1,932,315 for 1904:

	Mar. 11, 1905.	Mar. 4, 1905.	Mar. 13, 1904.
Total deaths, all causes.....	627	627	549
Annual death rate per 1,000.....	16.41	16.41	14.84
By sexes—			
Males.....	364	369	331
Females.....	263	258	218
By ages—			
Under 1 year.....	135	129	99
Between 1 and 5 years.....	70	60	41
Over 60 years.....	112	145	128
Important causes of death.....			
Acute intestinal diseases.....	28	24	20
Apoplexy.....	13	16	10
Bright's disease.....	38	33	38
Bronchitis.....	30	35	21
Consumption.....	82	73	86
Cancer.....	19	25	24
Convulsions.....	19	16	15
Diphtheria.....	2	9	6
Heart diseases.....	45	43	32
Influenza.....	8	11	3
Measles.....	10	1	1
Nervous diseases.....	22	28	14
Pneumonia.....	138	117	127
Scarlet fever.....	1	3	4
Smallpox.....	8	3	0
Suicide.....	8	10	5
Typhoid fever.....	8	3	9
Violence (other than suicide).....	25	26	20
Whooping cough.....	6	7	0
All other causes.....	117	144	113

More than one fifth of all the deaths reported during the week were attributed to pneumonia. The total 138 is twenty-one more than the previous week's and is the greatest number for any week of the current pneumonia season. As compared with New York the ratios of deaths from consumption and deaths from pneumonia to deaths from all causes, which, up to two weeks ago, were in favor of Chicago as to pneumonia, are now exactly the same. At the close of office hours on March 11th the figures for each city were as follows—the total period covered being between October 1, 1904, and March 11, 1905:

	Chicago.	Pneumonia
Total deaths.....	2,072	
Consumption.....	1,351	
Per cent. of total.....	11.5	17.3
	New York.	Pneumonia
Total deaths.....	5,533	
Consumption.....	3,673	
Per cent. of total.....	11.5	17.3

Up to February 25th, the consumption ratio was the same for each city—namely, 11.4 per cent.; but the pneumonia ratio was 17.4 per cent. for New York and 16.9 per cent. for Chicago.

Pith of Current Literature.

SEMAINE MEDICALE.

February 1, 1905.

1. Musical Aphasia, By G. MARINESCO.
2. Woody Phlegmon, By F. LEJARS.

1. Musical Aphasia.—Marinesco presents what little literature there is on this subject under the heading "des amusies." The recognition of this condition is comparatively recent. It exists in two forms, a motor aphasia for music similar to motor aphasia for words and an incapacity for instrumental music. Musical blindness, or alexia, is characterized by the loss of ability to read music, while the vision in general and the ability to read letters remains unimpaired. The exact seat of the different forms of "amusie" is almost wholly unknown.

2. Woody Phlegmon.—Lejars argues in favor of the existence of a phlegmon of this character with the characteristics described by Reclus in 1892 in opposition to the conclusion reached by Schmincke, who found by histological examination post mortem that a tumor which he had diagnosed as woody phlegmon, Holzphlegmon, was in reality a cancer.

February 8, 1905.

Surgical Intervention in the Face of Modern Ideas of Physiology and General Pathology, By A. CHASSIN.

Surgical Intervention.—Chassin protests against the frequency of operative procedures directed against the gall bladder, the appendix, and other parts of the intestinal tract on the ground that even though the local healing may be perfect and though the recovery be accompanied by a noticeable amelioration of the general condition, nevertheless certain physiological processes are definitely and permanently interfered with. Some of his statements are hardly convincing, one of which is that he has seen arteriosclerosis with renal trouble develop eighteen months after the removal of hæmorrhoids from a man 56 years of age without any other cause.

PRESSE MEDICALE.

February 15, 1905.

1. Treatment of Tuberculosis by Inoculations, By A. E. WRIGHT.
2. Action of Anæsthetics on the Blood, By P. EMILE WEIL.

1. Treatment of Tuberculosis by Inoculation.—Wright's paper is devoted to a discussion of the manner in which Koch's tuberculin protects against tuberculosis. The introduction of antiseptic substances into the organism has signally failed to accomplish the desired result, and a serviceable inoculation must be of a substance which gives rise to the formation of protective substances, or to bacteriotopical elements, in this case to tuberculo-topical elements. A protective substance is defined as one which enters into destructive chemical combination with bacteria or any foreign elements introduced into the organism through the veins or subcutaneously.

2. Action of Anæsthetics on the Blood.—

Weil's article is a brief summary of the effects noted by a large number of writers, mainly American surgeons, on the red and white corpuscles of the blood. Very little is known regarding the like effects of local anæsthetics, but one observer found a temporary diminution of the leucocytes for about two hours after obtaining lumbar anaesthesia with cocaine, not followed by any operation.

ZENTRALBLATT FUER INNERE MEDIZIN.

January 14, 1905.

1. Observations on the Mixed Saliva of Healthy and Diseased Persons, By R. FLECKSEDER.

1. Examinations of Saliva.—Fleckseder notes that the normal reaction of the saliva is alkaline, but is found to be acid in cases of diabetes, in neoplasms of the stomach and other organs, in leucæmia and pernicious anæmia, in jaundice, and less often in chlorosis. Ammonia is always present in normal saliva in small quantity. Rhodan and the chlorides are increased or diminished according to the disease, while albumin is present in a percentage of from seven to nine hundredths. The author was never able to demonstrate the presence of urea, uric acid, or biliary coloring matter, although urea was found in the saliva induced by pilocarpine and in uræmic subjects. In two severe cases of diabetes, sugar was always present, but was absent in eleven other cases of glycosuria.

Oligosialia (diminished saliva) is rarely idiopathic, but is commonly seen in severe constitutional diseases, diabetes mellitus and insipidus, profuse diarrhoeas and sweats, incessant vomiting, dropsy, cachexia, and anæmia accompanying carcinoma of the stomach and other malignant neoplasms, uræmia, pernicious anæmia, cirrhosis of the liver, and fever. It is usually then tenacious, cloudy, acid, and of a peculiar sweetish odor. The disturbances of oligosialia are often severe. The condition sometimes appears after ptyalism.

Ptyalism is marked by a clear, thin, alkaline saliva, with a decrease of rhodan. It is caused by stomatitis, pregnancy, the smell of favorite dishes, etc. It is also seen in cases of ulcer of the stomach, painful gastric affections, and nausea. Intermittent flow of saliva is observed in cases of neurasthenia, in the gastric crises of locomotor ataxia and in trigeminal neuralgia.

ZENTRALBLATT FUER GYNAEKOLOGIE.

February 4, 1905.

1. The Fate of Embolic, Displaced Placental Cells, By G. SCHMORL.
2. Perception of the Fœtal Heart Sounds in the Middle of Pregnancy, By O. VON HERFF.

1. Embolic Placental Cells.—Schmorl has made investigations into the question as to whether displaced cells of a normal placenta have the power to evoke progressive changes, such as chorioepithelioma. He examined the lungs of 150 women who died in different stages of pregnancy. In only one case toward the end of pregnancy did he find any pulmonary changes. In two cases in the fifth month of pregnancy he saw similar processes. All the cases were those of hydatid moles, so the author concludes that the cells of the normal placenta do

not give rise to such lesions. In one such instance, enormous masses of chorioepithelioma were found in the lungs.

ZENTRALBLATT FUER CHIRURGIE.

January 21, 1905.

1. The Technics of Gastrostomy and Jejunostomy. A New Operation, By J. ARCE.
2. Hedonal-Chloroform Narcosis, By W. MINTZ.

1. **Gastrostomy and Jejunostomy.**—Arce, moved by the thought that most patients subjected to these operations are very much emaciated and marantic, strove to devise a simple yet efficient operation. Under local anæsthesia, he unites the gastric mucosa to the peritonæum instead of to the skin. He first makes a vertical transmuscular incision which never reaches to the umbilicus, and then seeks either the cardia or the lesser curvature for a gastrostomy, or a suitable place in the jejunum about twenty cm. from the angle between the duodenum and the jejunum for a jejunostomy. These selected areas are united to the peritonæum. The rest of the peritoneal opening is then dosed with a continuous catgut suture and the skin is sutured. The opening of the stomach or intestine is postponed until adhesions have formed. The patient is then fed frequently in small quantities through a tube introduced into the wound. The results in the author's cases have been very satisfactory, fluids injected having no tendency to return through the fistula.

2. **Hedonal-Chloroform Narcosis.**—Mintz reports unfavorably on this combination for anæsthesia, basing his conclusions on 175 cases. In seventy-five instances, the hedonal failed in its anæsthetic effect. Another disadvantage is that the anæsthetist cannot be certain of the establishment of narcosis on account of the absence of some of the characteristic signs. Once a severe syncope was noticed and thirteen times decided weakness of the pulse was seen. The only advantage observed by Mintz was the absence of mental disturbance on the part of the patient on account of the preliminary anæsthesia induced by the hedonal.

January 28, 1905.

1. Anastomosis Between the Stomach and Œsophagus and Resection of the Thoracic Portion of the Œsophagus, By SAUERBRUCH.

1. **Anastomosis Between the Œsophagus and Stomach.**—Sauerbruch has succeeded, in dogs, in anastomosing the stomach and œsophagus and in resecting the thoracic portion of the œsophagus. He operates in the pneumatic chamber of his invention, and of eleven dogs operated on but three died. He was long unsuccessful, but finally succeeded by observing the most scrupulous asepsis, by doing away with sutures and using instead the Murphy button and by employing Lugol's solution to bring about adhesions. The operation seems simple and efficient, the œsophagus being reached through the fifth intercostal space. The resection of the œsophagus was achieved by intrapleural displacement of the stomach. For resection of the cardia, Sauerbruch performs thoracotomy first, then circular loosening of the diaphragm from the œsophagus, with mobilization of its lower part and isolation

of the vagi nerves. The œsophagus is then inverted into the stomach and held by silk sutures. Two weeks later gastrotomy is done and the inverted portion of the œsophagus excised. The author regards this as an ideal method for small tumors of the cardiac end of the stomach. He has convinced himself by experiments on the cadaver that the operation is possible on man.

FORTSCHRITTE DER MEDIZIN.

January 10, 1905.

1. Is Typhoid an Infectious Fever? By MEYER.
2. Subcutaneous Nourishment After Surgical Operations, By FRIEDRICH.
3. Renal Tuberculosis and the Results of Its Operative Treatment, By KRÖNLEIN.
4. Dietetic Treatment of Chronic Diffuse Intestinal Catarrh, By ROSENHEIM.

2. **Subcutaneous Nourishment After Surgical Operations.**—Friedrich suggests the direct introduction of nutriment into the tissues, especially after operations upon the abdominal organs in cases in which the digestive organs are entirely or partially unable to perform their functions. He has been experimenting in this direction for years and has found that heat units can be satisfactorily introduced by means of a two per cent. sodium chloride solution containing 30 to 35 parts per mille of chemically pure grape sugar. This solution should be boiled ten minutes and when cooled to the temperature of the body one to two litres may be injected daily under aseptic precautions. For the further production of heat 20 to 100 grammes of sterilized oil may also be injected. The production of a suitable albumenoid was extremely difficult, but he finally succeeded in producing a pepsin-fibrin-peptone which would not coagulate and which could be sterilized from ten to thirty minutes without disintegration. This was injected in twenty gramme doses, the equivalent of one hundred heat units, without discomfort, and was readily assimilated. Reduced to a formula Friedrich's method was as follows: in the morning 1,000 grammes of water containing 2 grammes of sodium chloride, 35 grammes of grape sugar and 15 grammes of peptone; in the afternoon the same quantity of water, sodium chloride, and sugar, and 5 to 10 grammes of peptone. In the interval between these two injections a single injection of 20 to 100 grammes of olive oil was injected. By this method the necessary quantity of proteids is supplied to the body so that in such conditions as peritonitis and perforation of the stomach and intestine sufficient nutriment may be introduced for as long a period as ten to fourteen days if necessary.

January 20, 1905.

1. Tuberculosis of the Kidney and Its Surgical Treatment, By KRÖNLEIN.
2. The Dietetic Treatment of Chronic, Diffuse, Intestinal Catarrh, By ROSENHEIM.

1. **Tuberculosis of the Kidney.**—Krönlein reports 51 cases of tuberculosis of the kidney, in 39 of which an operation was performed. In 92 per cent. of the cases only one of the kidneys was the seat of disease. The right and the left kid-

About one third of all the cases of surgical diseases of the kidney are tuberculous. Women were the subjects of the disease in 74 per cent. of the cases. This preponderance is due to the susceptibility of pregnant and puerperal women to the various forms of cystitis and pyelitis, to dislocation of the kidney, to twisting of the ureter, and to the consequent retention of the urine in the pelvis of the kidney. Nephrectomy was indicated in the majority of the cases. The specimens which were removed were divisible into two groups: 1. Those in which there had been tuberculous abscess with cavities containing pus and cheesy matter and with very little intact renal parenchyma remaining. 2. Those in which the kidney was still firm, in which the abscesses were small and located as a rule at the border between the cortex and the calyces. Krönlein agrees with the opinion of Steinthal and Baumgarten that renal tuberculosis is of hematogenous origin. In none of his cases could the continuity of the tuberculous process be traced from the genital organs by way of the bladder and ureters to the kidneys. With reference to prognosis he distinguishes: 1. The solitary tuberculosis in a kidney. 2. The combined kidney tuberculosis. In 12 of the 34 cases in which nephrectomy was performed no tuberculosis could be demonstrated in other organs. In the remaining 22 cases there was more or less evidence of similar disease in the lungs, urinary bladder, bones, or joints. The presence of tuberculosis in other organs does not contraindicate the removal of a tuberculous kidney if the remaining kidney is not diseased. In removing the kidney the loin incision was always employed. Of the 34 operations 24 were not fatal. Of 8 cases in which autopsy was performed, the remaining kidney was apparently sound in 6; in the two others the remaining kidney became tuberculous, the patients dying with uræmic symptoms. None of the operations resulted fatally immediately by reason of defective function in the remaining kidney. The combined variety of tuberculosis was found to give a less favorable prognosis than the solitary. Nephrectomy can hardly be considered a serious operation, in itself, its immediate mortality being only 5 to 6 per cent. As to the permanency of the results which follow nephrectomy Krönlein recalls several patients who continue well, though more than ten years have elapsed since the operation.

4. Dietetic Treatment of Intestinal Catarrh.

—Rosenheim observes that there would be difficulty in recommending a suitable routine diet for all forms of gastrointestinal disease. But it can safely be said that the food should be unirritating and assimilable. It has been wrongly assumed that milk is universally suitable for such troubles and the author has found that in the majority of cases it is not suitable, at least at the beginning of the disease. A milk diet may be considered after the small intestine has been brought to a quiet condition by several weeks of treatment with some other form of diet. On the other hand, the milk diet is never contraindicated for catarrh of the large intestine. The diet which is

recommended as suitable to bring about a quiet condition of the small intestine should contain 120 grammes of albumen, 200 to 250 of carbohydrates, and 40 to 50 of fats. It may be derived from meat, fish, eggs, sugar, white bread or zwieback, sago, macaroni, bouillon, thin soups, butter, tea, and red wine. Meat is suitable for the majority of cases of acute catarrh, and usually causes very little trouble. In some cases in which the small intestine is the seat of chronic inflammation it cannot be taken. When the stomach is in a condition of achylia, the undigested meat being found in the stools, or when there is an increased decomposition of albuminoid material on account of the intolerance of meat or fish by the diseased large intestine such food should, of course, not be administered. If the symptoms of disease of the stomach and large intestine predominate and the symptoms referable to the small intestine are correspondingly less pronounced the use of milk will be proper to supply the necessary albuminoids. If after a few weeks of milk diet the stools become normal and the general symptoms improve, small quantities of vegetables may be given every second or third day, including potatoes, carrots, and spinach, also tea, cocoa, and cereals. After four to six weeks meat, milk, and fruits may be added.

January 20, 1905.

1. The Spontaneous Disappearance of Opacities in the Crystalline Lens and Recurrent Clearness of the Same, By GREEFF.
2. The Permeability of the Human Body to the Röntgen Rays, By PERTHES.

2. **The Permeability of the Human Body to the Röntgen Rays.**—Perthes states that he has investigated experimentally the important question whether the Röntgen rays which have penetrated the skin will produce pathological and therapeutical results in the interior of the body similar to those which are produced by those which impinge upon the skin. He has reached the following conclusions: 1. The permeability of the soft parts of the human body is very similar to that of water, with the exception of the lungs and the fatty tissue which are specifically lighter than water. The lungs and fatty tissue are more readily permeable than water, while the other soft parts are slightly less permeable than water. 2. When the interior of the body is irradiated the intensity of the rays drops abruptly as they pass from the surface of the interior. Moderately soft tubes being used the intensity of the rays one centimetre below the surface is 50 to 60 per cent. of the intensity at the surface, at two centimetres it is 35 to 45 per cent., at three centimetres it is only 20 to 30 per cent. 3. The diminution in intensity takes place more slowly when hard tubes are used, but even with such tubes the intensity is less than 40 per cent. at four centimetres depth, and less than 25 per cent. at five centimetres. 4. The diminution in intensity occurs much more slowly if a layer of aluminum one millimetre in thickness be placed upon the surface of the body.

BERLINER KLINISCHE WOCHENSCHRIFT

February 6, 1905.

1. Syphilis of the Liver in the Diagnosis of Abdominal Tumors, By KOENIG.
2. The Origin of Immunity Against Typhoid Fever, By JUERGENS.
3. Experiments on the Gastric Secretion of Herbivora, By A. BICKEL.
4. A Case of Vegetating Pyodermitis, By R. LEDERMANN.
5. A New Method of Hæmostasis, By B. MUELLER.
6. Sprains of the Ankle (*Concluded*), By PELS-LEUSDEN.
7. The Results of Experiments of Inoculating Animals with Syphilis, By E. HOFFMANN.

1. Hepatic Syphilis and Abdominal Tumors.

—Koenig reports several cases of patients who, for a longer or shorter period, complained of pain in the region of the liver, anorexia, and loss of weight, in whom no functional hepatic disturbance could be demonstrated. Tumors, sometimes movable, sometimes adherent to the liver, were present, and gave the indication for operation. Diagnostically, Koenig points out, syphilis affects first the lobes of the liver, giving rise later to a diffuse hepatitis. The interstitial as well as the gummatous form of syphilis can give rise to tumor formation. Koenig says every case must be individually judged as to whether an operation is to be performed or not.

2. Typhoid Immunity.—Juergens narrates the case of a man who suffered from a severe attack of typhoid fever two months after recovery from typhoid. During his first attack agglutinins and bactericidal elements were found in the blood. The recurrence of the disease cannot, therefore, be ascribed to a lack of immunizing material since it took place at a time when the formation of immunizing substances was at its height. Immunity does not, therefore, depend exclusively upon changes in the serum. Epidemiological and individual factors must also enter into consideration of what constitutes immunity.

5. A New Method of Hæmostasis.—Mueller has prepared dressings impregnated with suprenin which can be conveniently used for stopping hæmorrhage. The dressings can be used for tamponade as well as for superficial areas.

6. Sprains of the Ankle.—Pels-Leusden says that an examination of about 6,000 Röntgen plates convinces him that a genuine sprain of the ankle, as it is generally understood, does not exist. In every case there is a fracture of one or both condyles or of the articular surface of the tibia.

7. Syphilis Inoculation.—Hoffmann shows that the inoculation of chimpanzees with human syphilis has actually been accomplished and that these animals can infect others. He expresses the hope that as a result of these experiments, a serum therapy for the disease may be evolved.

RIFORMA MEDICA

February 4, 1905.

1. Orchipin, a Preparation of Fresh Testicles in an Oily Vehicle, By M. SCIALLEO.
2. Serum Diagnosis in One Hundred Patients Presenting the Clinical Features of Typhoid Fever, By D. FALCIONI.
3. Decapsulation of the Kidneys According to Edebohl's

Method, in the Treatment of Chronic Interstitial Nephritis, By EUGENIO ARCOLEO.

4. The Pathogenesis of Sensory Dissociation of Central Origin (*Concluded*), By UGO BENENATI.

1. Orchipin.—Sciallero describes a new testicular preparation named orchipin, as an extract of the fresh testicles of the bull and the ram, made by dissolving the testicular substance properly prepared in olive oil. The testes are taken only from animals that have passed an examination by veterinary surgeons stationed at the slaughter house. The preparation occurs as a clear oily fluid which is neither alkaline nor acid in reaction, and does not contain any precipitable albumins. It is very rich in phosphorus and in lecithin. It can be given in large doses without producing any toxic effects.

2. Serum Diagnosis in Typhoid.—Falcioni found that the reaction was positive in 87 per cent. of a series of 100 cases in which the clinical diagnosis was typhoid fever. He concludes that the bacillus of Eberth is not the only, but certainly the principal germ causing typhoid infection. In five cases of paratyphoid he obtained reactions with the paratyphoid B. cultures, but not with typhoid bacillus cultures. In these five patients the disease presented the classical picture of typhoid fever, and only in two of them the malady was mild in character. This point is emphasized because some authors say that paratyphoid infection is usually mild in character—an observation which is not confirmed by the present author. He did not obtain a reaction in any case with paratyphoid A. bacillus, and corroborates the observations of other authors to the effect that infection with bacillus paratyphoid A. is very rare. Only in one patient could he obtain a reaction with paratyphoid A., but this was in the case of mixed infection. An interesting feature was the finding of a sharp reaction with cultures of bacterium coli in four patients suffering apparently from typhoid fever. The author thinks that in these cases the bacterium coli was responsible for the infection, inasmuch as in none of these four cases a reaction with typhoid bacilli could be obtained. In four other cases the reaction was absolutely negative. The author urges the necessity of repeating the reaction in doubtful cases, not only with culture of the typhoid bacillus, but also with the paratyphoid, A and B, and with the bacterium coli.

3. Renal Decapsulation.—Arcoleo, of Palermo, used Edebohl's method of decapsulation for a case of chronic nephritis with predominantly interstitial lesions. The chart of urinary analyses showed practically no improvement after the operation, but the patient improved somewhat in his general condition. The operation was performed only on one side, although both kidneys were diseased, as appeared from the separation of the urine by means of Downes's apparatus. The case therefore cannot be counted as evidence of the failure or success of the method in question. The author is fully conversant with the literature of the subject, and gives a clear exposition of the technics and rationale of the operation.

GAZZETTA DEGLI OSPEDALI E DELLE CLINICHE.

January 28, 1905.

1. The Diagnostic Value of Certain Leucocytic Formulæ in the Cerebrospinal Fluid, By C. P. GOGGIA.
2. Contribution to the Study of Auscultation Over the Mouth in Relation to Cardiopulmonary Respiration, By GIULIO BINETTI.
3. On the Diagnosis of Tumors of the Upper Pelvis, By RAFFAELLO CECCO.
4. Ligature of the Carotid Artery, By GAETANO AMENTA.
5. Contribution to the Treatment of "Infectious Fever," By CRESCENZO CONCA.
6. Arrhenal in Pædiatrics, By GIUSEPPE DALLA VECCHIA.

1. Value of Cytodiagnosis in the Cerebrospinal Fluid.—Goggia studied two cases of meningitis of diplococcic origin with reference to the value of cytodiagnosis. Two facts were noted in this investigation, which he thinks are of value: First, the constant predominance of small mononuclear elements in the cerebrospinal fluid of one patient, who died, and in whom the diagnosis was confirmed on autopsy. Second, the constant predominance of polynuclear elements even after the convalescence had set in in the second patient, who recovered. He thinks that the leucocytic formulæ which have been advanced by the French school are not sufficient, *per se*, to give us a definite diagnostic element, or to help us in the prognosis.

3. The Diagnosis of Pelvic Tumors.—Cecco considers the methods of diagnosing deeply situated tumors in the upper part of the pelvis, i. e., in the iliac region, and describes the following method which he worked out himself: The operator stands at the side of the patient, who is placed on an examining table. He presses one hand deeply into the abdominal cavity of the patient on the side on which the tumor is suspected, and with the other hand first flexes the patient's thigh, and then suddenly extends the limb, striking the table with the heel of the patient. At this moment, a distinct impact is felt by the abdominal wall if there is a retroperitoneal tumor present. The author convinced himself experimentally in the cadaver of the correctness of this method of examination. He believes that by more careful examinations of such tumors abdominal incisions could often be avoided and lumbar incisions or extraperitoneal cuts could be substituted, with a corresponding lowering of the mortality.

4. Ligature of the External Carotid.—Amenta ligated the external carotid in order to arrest hæmorrhage from a wound inflicted by an assassin in the parotid region, the injury penetrating into the pharynx. The patient was a robust man, but the loss of blood was very great. An incision was made with its centre at the anterior margin of the sternocleidomastoid, eight cm. in length, and the external carotid carefully isolated and ligated with No. 2 silk between the origins of the lingual and the external maxillary. The wound was drained with gauze for a day, but healed by primary union and the patient made an uneventful recovery.

2. On the Treatment of Suppurative Inflammation of the Leptomeninges, By V. A. OPPEL.
3. On the Connection Between Diarrhoeas of Bacterial Origin and Achylia Gastrica, By Z. F. ORLOFFSKI.
4. On the Influence of Dyes of the Aromatic Series on Digestion, By A. I. VINOGRADOFF.
5. On the Rupture of the Walls of the Vagina During Coitus, By I. S. BALLIN.

1. Treatment of Myomas in Pregnancy.—Mikhnoff concludes his analysis of this subject as follows: No operative interference is indicated in a case of uterine myomas in a pregnant woman when the growths do not produce any disturbances and occupy such a position that they do not interfere with the passage of the fœtus. If the growth occupies such a position that it can be removed without opening the cavity of the uterus, conservative myomectomy should be performed, and if necessary, this operation can be performed during the first months of pregnancy. If it is necessary to open the womb, the operation should be performed when the fœtus is eight months old, and then only when the indications are most urgent. Artificial labor should never be induced as a means of treating myomas of the uterus.

4. Action of Artificial Dyes on Digestion.—Vinoogradoff finds that the artificial dyes of the aromatic series which are often incorporated in food products, not only act as general poisons in the system, but also seriously affect digestion, their chief effect being a lowering of the digestive power of pepsin. Their exact mode of action and their influence on metabolism are still open questions.

5. Rupture of Vagina in Coitus.—Ballin reports the case of a woman who suffered extensive lacerations of the vaginal walls during her first coitus. She was 25 years old, and the sexual act seemed to have been perfectly normal, according to her account, except that she had held her knees bent upon her abdomen, pressing them into this position with her hands. Very profuse hæmorrhage occurred after the act. The external genitals were uninjured, but two tears passed through the hymen down to the base of this membrane. The vagina was filled with bloodclots, and the posterior vault showed a transverse laceration, which included a part of the left fornix. The small virgin cervix was completely torn away from the posterior wall, and was drawn forward. The author attributes the vaginal rupture in these cases to a congenital rigidity of the vaginal walls, and not to anything unusual in the sexual act.

January 22, 1905.

1. The Fear of Another Person's Eye, By V. M. BEKHTERIEFF.
2. Study of Malaria in Soth (a Town on the Coast of the Black Sea), By N. K. SCHULTZ.
3. Echinococcus Cysts of the Pelvis in Women. Their Diagnosis and Treatment, By B. N. ORLOFF.

4. Changes in the Morphology of the Blood Due to Chloroform Anæsthesia. By P. I. FIODOROFF.

1. **The Fear of a Stare.**—Bekhterief contributes an interesting study to the question as to the nature and significance of a state of mind in which a person fears a prolonged stare directed upon him by another. Recently Hartenberg described what he styles *la phobie du regard*, one of the varieties of which is the fear of another person's stare, which develops in persons who are naturally timid. Bekhterief claims priority in this matter, as he described a case of this kind in 1899. This was the case of a theological student given to masturbation who could not bear the look of another person, and therefore wore dark spectacles. In 1900 Bekhterief described three other cases of this kind. He found that, as a rule, these patients complain of a feeling of shame when some one looks steadily at them, and they imagine that when a person looks them in the eye their own eyes, or facial expression, betray the fact that they are given to onanism, that they are impotent, or have some other secret trouble from which they are suffering. The author classes these cases with the group of psychoses characterized by compulsory hallucinations and delusions. Very often the fear of meeting some one else's eye is associated with other compulsory acts, such as the compulsory smile which the author has described, or with the fear of blushing, etc. In other cases the fear of looking one in the eye is present in a pure or uncomplicated state. The treatment consists of the use of various methods of calming the excited nervous system, such as bromides, baths, and douches, together with an appropriate course of hypnotic suggestion.

3. **Echinococcus Cysts in the Female Pelvis.**—Orloff says that it is very difficult to diagnose the presence of echinococcus cysts in the pelvis in women. Of the three cases which he reports only one was properly diagnosed before operation. In the diagnosis in this case the principal reliance was placed on the history of the patient's illness. She stated that at first she noticed the appearance of a single tumor in the abdomen; then this tumor disappeared, and a whole series of similar growths developed in rapid succession. This meant that the first cyst had burst and that daughter cysts had developed. Primary echinococcus of the broad ligament is easily mistaken for cystic ovary, and the diagnosis in such cases is almost impossible. A useful method of diagnosis is the puncture of these cysts, followed by an examination of the fluid for the hooklets. The bruit which is said to be audible over such cysts is not a trustworthy sign, at least the author has never been able to hear it. If we can make out from the history that the patient has been in contact with dogs, and if we can exclude other diseased conditions of the pelvis, the diagnosis becomes somewhat more easy. The treatment must, of course, be operative, and with modern asepsis such makeshifts as puncture or the injection of antiseptics into the cyst, are not to be countenanced. Removal through the va-

gina has been recommended by several authors, but the best method is removal through an abdominal incision, as we then are sure to be able to deal with the case, no matter how complicated it may be. Possibly at the last minute the cyst may prove of ovarian origin. Another advantage of laparotomy is that we are more certain to remove all the cysts.

4. **The Blood in Chloroform Anæsthesia.**—Fiodoroff studied the morphology of the blood in forty-eight persons who had been placed under chloroform anæsthesia. He examined usually three specimens of blood—before, during, and after the narcosis. He found that an absolute leucocytosis appeared during chloroform anæsthesia, but he was unable to confirm the observation made by others in animals, to the effect that the leucocytosis of chloroform anæsthesia lasts for several days after the animal returns to consciousness. The leucocytosis which he observed took place at the expense of all varieties of white cells, but not equally so for all types. The young forms were most markedly increased. An increase in the young types of white cells was noted in 75 per cent. of all cases studied, and in some cases this increase amounted to one hundred per cent. of the original number of these cells. The mature white cells did not increase so markedly, and a leucocytosis of these was found in but fifty per cent. of the cases, although sometimes they were enormously increased. As regards the polynuclear or senile (over matured) cells, their increase was but insignificant as compared to the increase of the other types. The author offers an interesting theory deduced from his observations. He thinks that the leucocytosis seen in chloroformed subjects is an evidence of the defence of the organism against a poison which is invading it. This is the reason for the increase in the number of young cells which he has observed. If this theory holds good, then the lymphocytes have a protective action of their own and are not merely transition forms preliminary to the formation of polynuclear cells. This would be in correspondence with Ehrlich's theory that a polynuclear cell can be formed from specific tissue-elements without passing through the preliminary stage of a lymphocyte.

1. **Food Preservatives.**—Vaughan asserts that at the present time too little is known regarding the various substances which are used as food preservatives. Before a substance is legally sanctioned for use as a food preservative it should be proved to possess the following characteristics: (1) It must be a real preservative, keeping the food in a wholesome condition and not merely retaining the appearance of freshness while bacterial changes continue. (2) In the largest quantities used, it must not materially impair any of the digestive processes. (3) It must not be a cell poison, or if a cell poison in any amount, it must be added to foods only by persons qualified by special training and officially authorized, and foods containing these substances must be plainly labeled and the kind and amount of the preservative used must be made known not only to the buyer, but to each consumer.

2. **Gonorrhœa in the Female.**—Johnson quotes numerous authorities in order to show that gonorrhœa in the female is a prolific source of disease, sterility, and death. What the actual mortality of gonorrhœa is it is not possible to say. It has been estimated that forty to fifty thousand prostitutes die annually, and that thirty per cent. of the mortality is due to the direct effects of gonorrhœa. The author believes that it is probable that fully one hundred thousand women die of this disease, or of its sequelæ, each year.

3. **Purulent Conjunctivitis.**—Jackson calls attention to the fact that, in the newly born as well as in the adult, purulent conjunctivitis is not always of gonorrhœal origin. However, most of the cases followed by blindness are of specific origin. Prophylaxis is easy and effective. The Crêdè method is, as is well known, exceedingly efficient. As to legislation to prevent blindness from purulent conjunctivitis, two points seem worthy of attention: First. Social conditions that favor or oppose the spread of gonorrhœa are more important than any measures aimed directly at purulent conjunctivitis. Second. Gonorrhœa is a malignant contagious disease, and should be publicly recognized and dealt with as such in all its clinical manifestations.

BOSTON MEDICAL AND SURGICAL JOURNAL.

March 9, 1905.

1. A Clinical Report of 75 Cases of Arthritis Deformans (Chronic, Non-Tuberculous Arthritis),

By F. L. RICHARDSON.

2. The Complementary Relations of Glycuronic and Ethereal Sulphuric Acids and Their Pairings in Autointoxication, Typhoid Fever, and Cancer,

By A. E. AUSTIN and E. W. BARRON.

3. Dangers from the X Ray Atmosphere to the Operator. Their Prevention,

By H. W. VAN ALLEN.

1. **Arthritis Deformans.**—Richardson asserts that none of the classifications of chronic non-tuberculous arthritis so far advanced are wholly satisfactory. He therefore uses the term arthritis deformans in the sense in which Virchow used it, as it then does not assume either clinical or pathological distinctions. For the purposes of the paper the seventy-five cases studied are divided into two general groups. The first group comprises, in a general way, the joint diseases of the young. They usually start acutely, subside and not infrequently recur. The second group comprises the joint affections of the physiologically old and really old. In this class of cases the deformity is usually marked, and there are considerable changes in the bones or cartilages of the affected joints. The author concludes that the analogy, which Bradford has suggested, between arthritis deformans and arteriosclerosis appears to be a very close one. In arteriosclerosis the causes to which the disease has been ascribed are innumerable and the manifestations may be widely varied. The condition may be widely distributed, or narrowly circumscribed; there may be ulceration, calcification, or even formation of true bone. Because of these numerous manifestations it seems to the author that it cannot be said that we are dealing with many diseases. He has come to this conclusion, not only from clinical cases, but also from the study of many pathological specimens from cases of arthritis deformans. Why in one case there is new formation of bone and in another absorption is at present as much unknown as are the varied conditions that give rise to the disease. That the disease often is the result of some general alteration in the body metabolism seems possible.

2. **Glycuronic and Ethereal Sulphuric Acid.**—Austin and Barron, from a series of experiments, conclude: That aromatic bodies unite both with ethereal sulphuric acid and glycuronic acid, which apparently have a complementary relation to each other, but that the former is always first saturated before union commences with the second. The glycuronic acid apparently varies very decidedly in amount, due to causes of which we have at present no exact knowledge, but it is not necessarily associated with the increase of the pairing body, nor with the diminution of oxidation. Furthermore, there is always present an excess of sulphuric acid beyond the demands of the pairing body.

3. **Dangers of the X Ray to the Operator.**—Allen enumerates some of the well known dan-

gers to which x ray operators are exposed and describes the devices he has adopted in order to avoid them. Seven selected cases are reported of patients who were rayed in the genital region. These cases were studied in an effort to determine the influence of the Röntgen rays on the genital functions. The data reported do not warrant positive conclusions. It would seem, however, that prolonged exposure to the x ray causes the disappearance of spermatozoa from the seminal fluid, but that the sterility so produced is not permanent.

AMERICAN MEDICINE.

March 11, 1905.

1. The Medical Treatment of Gastric Ulcer,
By FREDERICK P. HENRY.
2. Advances in the Physiology and Pathology of the Pancreas, and Their Application to the Diagnosis of Pancreatic Diseases,
By JOHN C. HEMMETER.
3. A Consideration of Fibroid Tumors of the Uterus, Based Upon a Study of a Series of 210 Cases Treated Surgically,
By J. CLARENCE WEBSTER.
4. Tuberculosis of the Gastrointestinal Tract: Report of a Case of Perforation and Partial Stenosis of the Bowels,
By J. A. LIGHTY.
5. Iodine in the Treatment of Postoperative Sepsis,
By JAMES HAWLEY BURTENSHAW.
6. The Ætiology and Treatment of Acute and Chronic Rheumatism,
By G. MORTON ILLMAN.

1. **Gastric Ulcer.**—Henry advocates the medicinal treatment of gastric ulcer. He asserts that the claim made by Leube that from seventy-five to ninety-six per cent. of all cases of gastric ulcer are curable by medical means is well founded. The important point to bear in mind in treating gastric ulcer, as well as any other disease, is to follow a definite system. The author reviews the teachings of Ewald and Leube regarding the management of gastric ulcer, and describes his own routine. Briefly this is: (1) For the first few days to one week, rectal feeding. (2) For the next two or three weeks, diluted milk if it is well borne. (3) Raw or soft boiled eggs, mutton and chicken broths follow the milk diet for some weeks more, at the end of which time a solid diet is gradually resumed. (4) The most useful drugs are: subnitrate of bismuth, in half drachm doses, nitrate of silver, morphine, and cocaine hydrochloride. The use of Carlsbad salts is probably of benefit. An aluminate of iron may be often given with advantage.

2. **The Pancreas.**—Hemmeter's paper is too detailed and covers too many questions to allow of its being condensed. The article consists of fourteen sections devoted to the following subjects: (1) Historical review. (2) The anatomy and physiology of the pancreas. (3) Development and pathology of the islands of Langerhans. (4) Acute and chronic pancreatitis. (5) Chronic indurative pancreatitis. (6) Adrenalin glycosuria and certain relations between the adrenal glands and carbohydrate metabolism. (7) Pancreatic diseases simulating cholelithiasis. (8) Relations of the pancreas to diabetes and glycosuria. (9) Histological examinations of the pancreas in diabetes mellitus. (10) "Symposium" on pancreas and pancreatic disease. (11)

Fat necrosis. (12) Prospect of diagnosticating pancreatic insufficiency from defective proteolysis, amyolysis, and adipolysis. (13) Defective amyolysis and its significance. (14) Non-digestion of nuclei in meat fibre a criterion of pancreatic insufficiency.

3. **Fibroid Tumors.**—See this *Journal*, Vol. LXXXI, page 512.

5. **Iodine in Sepsis.**—Burtenshaw reviews the method advocated by Pryor for combating sepsis of uterine origin. Within the past year the author has treated three cases of postoperative sepsis by means of iodine or one of its preparations. His results were most unsatisfactory. Yet he believes in the principle of the method. "I must confess that my own experience with iodine in these cases has been distinctly disappointing; yet I am convinced that further development of treatment along the lines indicated will, in the near future, yield brilliant results."

6. **Rheumatism.**—Illman believes that rheumatism is closely associated with an abnormal condition of the gastrointestinal tract. He therefore holds that the treatment of the condition should not be reduced purely and simply to the administration of salicylates.

MEDICAL RECORD.

March 11, 1905.

1. The Treatment of Epidemic Cerebrospinal Meningitis by Diphtheria Antitoxine, By EDWARD WAITZFELDER.
2. Chronic Myositis Rheumatica and Its Treatment by Massage, By GUSTAF NORSTRÖM.
3. Radical Operation for the Removal of a Bullet Weighing 70 Grains, Embedded in the Internal Wall of the Middle Ear, with Decided Improvement in the Subjective Symptoms, By M. D. LEDERMAN.
4. Aortic Regurgitation with Chronic Miliary Tuberculosis in a Man Twenty-two Years Old, By MEDWIN LEALE.
5. A Case of Cicatricial Stricture of the Esophagus, By A. B. ATHERTON.

1. **Epidemic Cerebrospinal Meningitis.**—Waitzfelder has treated seventeen cases of cerebrospinal meningitis with repeated injections of from 6,000 to 10,000 units of diphtheria antitoxine. The results are most encouraging. If it fulfills present hopes to Wolff, of the Hartford, Conn., board of health, will be due the credit for discovering this mode of treatment. Part of the author's cases are still under treatment. To summarize: There have been seventeen patients under observation, of whom 5 have recovered completely; 3 have died, of whom 2 were adults; 9 patients are still under treatment. Of these, 5 show marked improvement as to indicate probable recovery (4 being convalescent). Of the remaining 4 cases, all are in a serious condition, and prognosis is impossible at the present time.

2. **Myositis.**—Norström asserts that chronic myositis is of much more frequent occurrence than is generally supposed. He reports a large number of cases, treated by him by massage, and which eventually recovered. The reason the condition is considered rare is because it is so frequently mistaken for other affections.

5. **Stricture of the Œsophagus.**—Atherton reports the following case: Man, 26 years old, swallowed some lye. Stricture of the œsophagus followed recovery from the acute poisoning. November, 1903, operation for the stricture. This was followed by gradual dilatation, until a No. 22 bougie, French scale, could be easily passed. It was noted, however, that if the bougie was left out of the œsophagus even for a few hours the stricture would contract considerably. Therefore, the man is obliged to wear the bougie almost constantly. He removes it for meals and his condition is said to be tolerable, though scarcely comfortable.

MEDICAL NEWS.

March 11, 1905.

1. Uric Acid—Its Influence in Gout,
By CHARLES C. RANSOM.
2. Objective and Subjective Symptoms in Kidney Disease,
By C. L. GIBSON.
3. Laboratory Findings in Surgical Diseases of the Kidney,
By FREDERIC E. SONDERN.
4. The X Ray in Kidney Disease,
By LEWIS GREGORY COLE.
5. The Cystoscope and Ureter Catheter in the Diagnosis of Surgical Disease of the Kidney and Ureter,
By F. TILDEN BROWN.
6. Exploratory Operations Relating to the Kidney,
By HOWARD LILIENTHAL.

1. **Uric Acid.**—Ransom traces the origin of the uric acid delusion from the days of Garrod and Haig. To the question: Is uric acid ever retained in the blood in excess? he answers yes. To the question: Is uric acid toxic when retained in the blood? he answers no. The author, of course, does not mean uric acid in an uncombined state. To date there is no scientific evidence that uric acid is the cause of gout, or, in fact, of any other disease. The cause of gout is still a mystery.

2. **Surgical Diseases of the Kidney.**—Gibson asserts that notwithstanding the great progress that has recently been made in laboratory methods and in the invention of numerous mechanical devices for aiding diagnosis the chief reliance in reaching a correct conclusion must still rest on a correct interpretation of the objective and subjective symptoms. It is therefore of the utmost importance that these symptoms should be well understood. The author appraises each of the most characteristic signs and symptoms of surgical kidney, and concludes his paper with a table giving the chief diagnostic factors of nine of the most important surgical diseases of the kidney.

3. **Laboratory Findings.**—Sondern asserts that the best results in diagnosis will not be attained until the laboratory worker becomes as closely associated with the clinician as the internist should be with the surgeon. The author points out at length the progress which has been made in laboratory diagnosis, and holds that the best methods are too time consuming and elaborate to allow of their adoption by the clinician.

4. **The X Ray in Kidney Disease.**—Cole holds that a positive diagnosis of kidney stone by means of the x ray should be regarded as practically absolute. A reliable negative diagnosis can only be reached when "the ray of selective absorption" has been utilized. This ray is a discovery of the author, and he will soon publish the chief facts relating to it.

5. **The Cystoscope.**—Brown defines the value of simple cystoscopy and cystoscopy with catheterization of the ureters in suspected kidney disease. Half a dozen cases are recorded in order to illustrate the results that may at times be achieved by an intelligent use of the cystoscope.

6. **Exploratory Operations.**—Lilienthal holds that when all other methods have failed in shedding light on a case of suspected kidney disease then it is the time for an exploratory operation. He sums up his advice thus: A. Exploratory operation is probably the surest method of diagnosis in suspected surgical disease of the kidney. B. The indications for its performance are: (1) In hæmorrhage from one or both kidneys when other measures have failed to check the bleeding and the danger signals appear. (2) In palpable tumor with symptoms pointing to renal disease. Sometimes even to establish whether the tumor is in the kidney, gall bladder, or some other organ. (3) Without palpable tumor when there is reason to suspect surgical renal disease and when medical, hygienic, and local treatment fail to give relief. C. Exploratory incision may be necessary to demonstrate the condition of solitary kidney.

9. Electrolysis: an Improved Method of Operating on Superfluous Hairs,
By B. SQUIRE.
10. Laceration of the Abdominal Wall, the Result of Bear Bite, Simulating an Abdominal Tumor,
By V. S. UMACHIGI.

1. **Bacteriology of Peritonitis.**—Dudgeon and Sargent, in the Erasmus Wilson lectures, give the results of their researches into the bacteriology of peritonitis, based upon the systematic examination of the peritonæum in 270 cases operated in at St. Thomas's Hospital. The first result of their studies

has been to cast very considerable doubt upon the existence of "chemical" peritonitis. In every case of intraperitoneal hæmorrhage, a white staphylococcus was obtained from the blood clot. Slight as are the pathogenic properties of the staphylococcus albus, the authors are of opinion that the febrile disturbances so frequently found after effusion of blood into the peritoneal cavity are due to the presence of this organism and not to any hypothetical toxic substance produced by the coagulation of the blood. In nine cases of perforated gastric ulcer they have isolated a streptodiplococcus in from the edge of the ulcer in every case; from the peritoneal exudate in four instances out of seven. The organism occurs as a diplococcus, is non-motile, and has no capsule. It stains well with the ordinary dyes, but does not retain Gram's stain. It grows well on all the ordinary media: on agar the colonies are small, opaque, and isolated, like those of streptococcus. The organism is not pathogenic to guinea pigs or mice. The rôle of the typhoid bacillus in peritonitis is very doubtful: in most cases it is the colon bacillus which is the active cause of trouble.

2. Shifting Dulness.—Godlee states that dulness in the back which shifts on placing the patient on his face or upon the opposite side, usually means that the pleura is healthy and that the cause of the dulness is subdiaphragmatic. The dulness resulting from a localized empyema if there is no gas in the cavity, does not shift at all. The dulness from a pleural effusion shifts very little, if at all. The presence of pleural effusions limits or prevents the shifting of the dulness caused by solids or fluids below the diaphragm. A dulness which disappears under an anæsthetic must not be neglected, but it must be suspected that adhesions do not extend so far as they might before the administration be supposed to do. In a suspected empyema where the dulness disappears under the anæsthetic, the case will probably prove to be one of pneumothorax. In cases of intestinal obstruction with much distention it is impossible to say whether or not there is free fluid in the peritoneal cavity because the flanks may be dull when the patient is lying on the back, but resonant in the upper flank when he is lying on his side.

3. Hyperplasia of the Mucous Membranes.—Semon reports a case with a history of long standing throat trouble, in which on examination an almost lardaceous condition of the uvula was seen. The uvula and adjacent parts of the soft palate were infiltrated, yet quite smooth to sight and touch, and were of a peculiar yellowish color, resembling that of a lardaceous kidney. In the larynx there was a similar condition of the mucous membrane over the right arytenoid cartilage. The voice was normal and there was no pain. All forms of treatment were of no avail. This is the third case of the kind that has come under the writer's observation. In both the others there had been a return to perfectly normal conditions without obvious cause. He has collected seven cases from the literature. There seems to be no specific microorganism, and tuberculosis, syphilis, and rhinoscleroma can be eliminated in all. It is assumed that the pathology of the new affection is one of progressive, mostly interstitial, hyper-

plasia, but the disappearance of the condition in the author's cases speaks against such a view.

4. Pneumonic Endocarditis and Meningitis.

—Livingstone and Jubb report a case of pneumonia, occurring in a man, aged forty years, which was complicated by endocarditis and meningitis, both of which were diagnosed during life. The crisis took place on the ninth day, and the patient was apparently convalescent for three days thereafter. On the eighteenth day, after irregular temperature, sweats, and præcordial pain, the diagnosis of endocarditis was made. On the twenty-fifth day, after some days of severe headache, he had two convulsive seizures, and died two days later. At the autopsy there was found only moderate resolution of the affected lung, with mitral valvular vegetations, and a diffuse purulent meningitis.

5. Antistreptococcic Serum in Septicæmia.

—Cressey reports a case of acute septicæmia occurring in a girl, aged fifteen years, following a cut of the foot. The wound became infected and although vigorous local treatment with extensive incisions was carried out, general septicæmia developed. Eighteen days after the accident antistreptococcic serum was first used: it was continued in doses of ten c.c. daily until in all 235 c.c. had been used. An empyema developed, and the patient was not convalescent until forty-five days after the injury.

8. Prostatic Enucleation.—Freyer calls attention to the great success of total enucleation of the prostate in advanced old age. Of 134 patients 8 were octogenarians. Seven are alive and in excellent health and all able to retain and pass urine normally. The remaining patient, after recovering from the operation, died suddenly of heart disease. The author gives the details of the eight cases, with illustrations of the prostatic glands removed.

9. Enelectrolysis.—Squire gives this name to his improved method of operating on superfluous hairs. He pulls out the hair first with tweezers, and then passes the electric needle into the hole left by the extraction of the hair. The operation becomes much more certain, and the pain and scarring are much less.

BRITISH MEDICAL JOURNAL.

February 25, 1905.

1. A Case of Multiple Disease of Joints in a Young Child.
By W. H. WHITE
2. On a Case of Acute Lymphæmia in a Child.
By E. J. McWEENEY and D. J. FARNAN.
3. A Case of Acute Lymphæmia, By E. J. McWEENEY.
4. Acute Lymphatic Leucæmia, with a Report of Five Cases,
By T. McCRAE.
5. A Case of Acute Lymphatic Leucæmia.
By W. D. DONNAN.
6. Notes on the Microscopical Examination of Bone Marrow.
By C. P. JONES.
7. Clinical Methods of Enumerating Leucocytes,
By E. TURTON.

1. Multiple Joint Disease.—White's article is based on the case of a boy aged five years, complaining of swelling of many joints and enlarged lymphatic glands. He considers in turn the va-

rious conditions which might be affecting the child, excluding each, and giving the reasons therefor. Among such conditions are: (1) osteoarthritis, where the x rays should show evidences of bony enlargement; (2) rheumatic fever or the rheumatic state, where there should be endocarditis, subcutaneous nodules, or a history of erythema, amygdalitis, chorea, or of a rheumatic tendency in the family; (3) syphilis, with a history of congenital syphilis, bony outgrowths or fibrous adhesions about the joints; (4) acute or subacute pyæmia; (5) gonorrhœal arthritis; or (6) tuberculosis. The case here reported conforms to a type of joint disease first described by Still, and characterized by chronic progressive enlargement of joints associated with a general enlargement of the glands and spleen. The onset is insidious and occurs before the second dentition. The joints are thickened, smooth, and fusiform, with none of the angular irregularity of osteoarthritis. Pain is absent and there is marked limitation of movement—chiefly of extension. The affection is symmetrical and the muscles which move the joints show early chronic wasting. The glandular enlargement is general, but affects primarily and chiefly those related to the joint involved. The glands are separate, not tender, and do not break down. The disease is, in some obscure way, of nervous origin.

2, 3, 4, and 5. Acute Lymphatic Leucæmia.—McWeeney and Farnan report a case of acute lymphæmia occurring in a girl aged three years, and which proved fatal after a duration of three weeks. The case agrees with the clinical pictures of acute leucæmia in its sudden onset, rapid course, moderate enlargement of lymph glands, enlargement of spleen, hæmorrhages in skin and mucous membranes, and oral fætor. In the blood there was an enormous preponderance of hyaline mononuclear leucocytes, the larger variety predominating; the polynuclear neutrophils and all forms of granule cells were very rare, also both varieties of nucleated red corpuscles. McWeeney reports a similar case occurring in a youth, aged nine years, and lasting nine weeks. Spleen and glands were moderately enlarged, and the course of the disease was characterized by fever, hæmorrhages, and increased uric acid excretion. The large hyaline mononuclear cell with basophile protoplasm predominated in the blood, forming 95 per cent. of the leucocytes. The myeloid element in the bone marrow was completely suppressed, with a consequent total absence of granule cells from the blood. Exceptional points were the severe anæmia (820,000); the large proportion of leucocytes to red cells (one to eight at first, and at the end one to one); the absolute number of lymphocytes (over 700,000); and the great enlargement of the thymus. The lymphoid tissues throughout the body were abnormally active and flooded the blood with lymphocytes. This activity was accompanied by a rejuvenescence of lymphoid tissue in places where it only exists in traces in adult life—*e. g.*, the bone marrow, liver, and kidneys. The behavior of the lymphoid tissue strongly resembles that of malignant new growths, the proliferating cells show-

ing a tendency to spread in all directions round their focus of origin. These proliferating cells were of a distinctly embryonic type, resembling the so called "mother" cells, rather than differentiated leucocytes. McCrae reports the cases of acute lymphatic leucæmia coming under observation at the Johns Hopkins Hospital since its opening—five in number. All the cases occurred in males, from three to twenty-one years of age. In three the onset was abrupt. The general symptoms were fever, weakness, hæmorrhages, and a rapidly progressive downward course. Pallor was a striking feature in all the cases. The average duration was six weeks: it varied from twelve days to eight weeks. Treatment had no influence. In every case the lymphocytes were over 90 per cent. of the total leucocytes. In three the prevailing cell was the small lymphocyte. As a rule, the rapid cases with hæmorrhage show a predominating lymphocyte of the large type. In conclusion the writer emphasizes the following points: 1. That in the majority of cases of acute leucæmia there is a rapid destruction of the red cells with the blood features of a severe primary anæmia. 2. That the essential changes in acute leucæmia are in the bone marrow. 3. That certain cases seem to justify the term of "leucanæmia" suggested by Leube. 4. That more attention should be paid to the changes in the red cells and the probable similarity to pernicious anæmia definitely decided. 5. That the clinical features of acute leucæmia suggest its being an acute infection, and perhaps a distinct disease from chronic leucæmia. Donnan reports a case of acute leucæmia in a boy, aged twelve years. There was no palpable lymphatic enlargement, but the spleen was moderately enlarged. A violent attack of nose bleed set in about two weeks after patient had come under observation, and the patient died five days later. The size of the spleen was rapidly reduced by the nasal hæmorrhage. The patient did not appear to die from loss of blood, but rather from an acute septicæmia, with high temperature and a steadily increasing pulse. The epistaxis could always be controlled by plugging. The white cells were almost exclusively large lymphocytes.

6. Examination of Bone Marrow.—Jones describes the method of obtaining bone marrow, and of preparing and staining specimens for microscopical examination. The marrow is emulsified with a ten per cent. solution of neutral glycerin, and from this smears are made and stained with Jenner's blood stain. Marrow contains connective tissue, fat, blood vessels, lymphatics, nerves, and particular cell elements, characterized by a peculiar transitional nature and a tendency to produce atypical forms. The red cells comprise the non-nucleated red cells of the blood and the nucleated red cells of the marrow. The leucocytes are classed in two divisions, the granular and non-granular. The granular group comprises giant or mother cells, and lymphoid or primitive cells. The non-granular group comprises coarse oxyphile cells, fine oxyphile or neutrophile cells, amphiphile cells, coarse basophile cells, fine basophile cells, and polymorphonuclear leucocytes.

Letters to the Editor.

STERILITY AND THE X RAY.

PHILADELPHIA, February 18, 1905.

To the Editor,

Sir: I fear your editorial Sterility and the X Ray is possibly too severe and alarmist in its nature. If the x ray had been proved to produce sterility, that would in no way endanger patients placed under it for examination. Such changes could occur only as the result of repeated and prolonged exposures, as in therapeutic work. In those cases, as of malignant disease of the pelvic viscera, such an action would be beneficial, if we can judge from the oophorectomies advised in cases of mammary carcinoma. But under such circumstances sterility would be certain and out of the field for consideration. Under no conditions could the necessary exposures during diagnostic examinations produce such a result.

CHARLES LESTER LEONARD.

3501 BARING STREET,
PHILADELPHIA, February 18, 1905.

To the Editor,

Sir: The enclosed reprint, which is of interest from several standpoints, is especially so upon the subject of x ray as the cause of sterility, that has lately attracted so much attention. By carefully reading, it will be noticed, pregnancy occurred while the patient was still under treatment. This was much to the surprise of the woman herself; as she expressed it, "she thought that her organs were too diseased for conception." Notwithstanding, in the summer of 1904, about a year after treatment, she had another miscarriage, and it might be stated here that the cause of these frequent miscarriages was entirely with the woman herself.

In regard to the experiments upon this subject, they must be taken for what they are worth. At the same time it must be remembered that in these instances the experiments were conducted with the idea of producing degeneration. Was time allowed for regeneration before the animal was killed? When one reviews the effect of the ray upon other specialized epithelial tissue, the hair, for instance, it would seem that these tissues should also undergo the same repair.

Much more could be said upon this subject but for the lack of time. This case, however, should be put upon record to combat experiment with clinical evidence.

WILLIAM S. NEWCOMET.

A CORRECTION.

NEW YORK, February 27, 1905.

To the Editor,

Sir: I beg respectfully to call your attention to an error in an article quoted from the *Alkaloidal Clinic* on page 391 of the current number of the *Journal*, referring to the removal of naevi. The sentence in question reads: "The amount of current employed depends upon the distance the

needle has been inserted, but usually is from $\frac{1}{2}$ ampère to 8 milliamperes." This should read, referring to the ampérage: "Usually is from $\frac{1}{2}$ to 8 milliamperes," since $\frac{1}{2}$ ampère is equal to five hundred milliamperes, which would exceed the current used in the destruction of any tissue, no matter of what nature.

FREDERICK S. KOELL.

LOCOMOTOR ATAXIA OR BURSITIS?

208 WEST ONE HUNDRED AND TWELFTH STREET,
NEW YORK, February 23, 1905.

To the Editor,

Sir: In an article which appeared in the *Journal* for February 18th, Locomotor Ataxia Successfully Treated with Ultraviolet Rays, by J. Monroe Liebermann, M. D., Case III is reported as one of locomotor ataxia, cured with the ultraviolet ray.

My excuse for writing is to prevent the recording of a supposed case of locomotor ataxia as cured by the ultraviolet ray.

This patient is known by me to have had a chronic bursitis (probably gonorrhoeal) of the bursa between the tendo Achillis and the os calcis (not behind the tendo Achillis, as the doctor states; the bursa is in front of the tendon, and there is no "synovial sac" behind the tendon).

I did advise removal of this bursa, since no other treatment was satisfactory, and if the doctor has been successful in curing this patient of his pain and bursitis with the ultraviolet ray, so much credit to him for that, but let him not place on record a case as one of locomotor ataxia cured by the ultraviolet ray when such patient has no sign of locomotor ataxia.

Surely the doctor is not able, with the "ultraviolet ray in combination with peripheral treatment with static electricity" applied in the "lumbar region," and "locally galvanism," to cure and restore to function a Charcot's joint as he reports, or regenerate organically destroyed posterior roots and dorsal columns of the cord, whereby the knee jerk would again be normal, as well as restore coordination.

I am positive this patient has no Argyll Robertson pupil or any other sign or symptom of locomotor ataxia. It was a case of bursitis plain and simple.

LOUIS FRIEDMAN.

CEREBROSPINAL MENINGITIS PROVING FATAL IN EIGHT HOURS.

121 WEST NINETY-FIFTH STREET,
NEW YORK, March 5, 1905.

To the Editor,

Sir: Unless I am greatly mistaken an epidemic of cerebrospinal meningitis is or soon will be under way in this city. I have seen an unusual amount of it in coroner cases during the past two months. It has not been recognized by the attending medical men as meningitis; why, I do not know. It might be well to relate a case in point where a diagnosis was not even attempted prior to my visit. A girl, nineteen years old, working in a bakery, was taken ill with a chill at noon. She went upstairs in a loft

and rested on some old bags. She did not go home at once, because her fellow workers could not get off. At 1 p. m. she had severe vomiting spells and chills, and following on this fever, pain in her head, and not headache, the pain sharp and deep in her brain, she said. She grew better at 4 p. m., when again she had more chills. At 6 p. m. she went to her home with a friend. She had to get off the car four times because of vomiting. Twice she went to a drug store and the clerks gave her sodium bicarbonate tablets. At seven o'clock she arrived at her home, fell exhausted on the bed, cried with pain, and vomited, after which she said she felt better. She then began to sing and talk incoherently, and at 8 o'clock the same evening she had a convulsion and died. The autopsy showed the meninges inflamed, with considerable exudate at the base. What makes this case noteworthy is the short period from the onset to death, viz., eight hours.

PHILIP F. O'HANLON.

Proceedings of Societies.

OBSTETRICAL SOCIETY OF PHILA- DELPHIA.

Meeting of Thursday, January 5, 1905.

(Continued from page 515.)

The President, Dr. RICHARD C. NORRIS, in the chair.

Dr. BARTON COOKE HIRST referred to his record of 189 fibroid tumors treated by some form of surgical procedure. Twenty-seven per cent. were treated by myomectomy; sixty per cent. by hysterectomy. Vaginal enucleation, oophorectomy, and ligation of the uterine arteries made up the remaining thirteen per cent. He had seen the following degenerations: Three sarcomatous, five cystic, four necrotic, two myomatous, and one carcereous. In about fifty per cent. there was some pathological conditions of the tubes and ovaries, usually in the shape of old adhesions, occasionally a hydrosalpinx, and very rarely indeed a pyosalpinx, not in two per cent. of the cases. There was an associated adenocarcinoma of the corpus in one case. Personally Dr. Hirst had found the use of electricity the most useful palliative treatment of hæmorrhage for the time being in fibroid tumors, but never had seen a tumor reduced in size or the condition benefited in any other way by this agent. The positive pole, however, of a galvanic current in the uterine cavity, with a current of 40-60 milliamperes, he had found to check hæmorrhage in suitable cases more surely than any other means he had tried. He believed there were a number of cases which might require nothing else, if the tumor was small, was not growing, showed no signs of degeneration or inflammatory complications, was not causing pressure symptoms, and exerted no deleterious influence on the general health.

Dr. CHARLES P. NOBLE was gratified to find in the literature upon fibroids in the last four years that conclusions in cases studied had agreed practically with his own. The chief point for discussion, he thought, was that of whether fibroids should be treated from the standpoint of symp-

toms or from that of the life history of these growths. Personally, he believed that in the future they would be treated from the latter, just as ovarian growths were studied rather than from the standpoint of symptomatology. He regarded Dr. Webster's paper as important and interesting because the deductions were the result of actual study of the facts in his series of cases. He thought it a remarkable fact that in 210 cases there was not a single case of adenocarcinoma of the corpus uteri. In the cases reported by Dr. McDonald, the Johns Hopkins Hospital, and himself, he said, there had been excess in occurrence of adenocarcinoma of the corpus uteri, this being so marked as to be the basis for the opinion that fibroid tumor of the uterus was a predisposing cause of adenocarcinoma of the corpus uteri. The complications in the appendages were much greater in number in Dr. Webster's cases than his own, particularly the left inflammatory complications.

In reference to total extirpation of the uterus *versus* supravaginal extirpation, out of about 700 hysterectomies, so far as Dr. Noble's knowledge went, there had been only two cases of carcinoma of the cervix following supravaginal amputation of the uterus. In one case the condition was doubtless overlooked at the time of operation, as carcinoma of the pelvis developed promptly. In the other case, in which there was supravaginal amputation for inflammatory disease, epithelioma of the cervix developed four or five years later. This factor, therefore, in his judgment, did not play a large rôle.

Dr. Noble had never considered that myomectomy could play a large rôle in the treatment of fibroids. Guided by his own statistics, he might be in favor of myomectomy, as he had had but one death, and that in a case of sloughing fibroid removed *per vaginam*, but he attributed his good results to care in the selection of patients. He had had a number of patients bear children after myomectomy. The cases should be carefully selected, and the desire of the patient should be a factor in the case.

It had not been Dr. Noble's experience that patients after hysterectomy had been especially troubled with the menopause symptoms, nor had he seen, in the considerable number of cases in which he had left an ovary, that there had been any difference in the sequel, whether the ovaries had been removed or left behind. In a large percentage of the cases, he thought, the troublesome symptoms were greatly exaggerated.

Dr. JOHN G. CLARK spoke especially upon the three following points: (1) the possibility, after a supravaginal hysterectomy, of a malignant involvement of the remaining stump; (2) the benefits of leaving the ovaries behind in cases of fibroid tumors; (3) the effect of fibroid tumors in the production of cardiac disease. Relative to the first point, he said that unquestionably a supravaginal amputation of the uterus was much easier, and he believed in the end gave a more satisfactory result, so far as concerned keeping the pelvic floor intact, than that following pan-hysterectomy. Therefore, from the mere anatomical standpoint, he considered it preferable

to leave the cervical stump. On the other hand, the objection which had been offered to the partial operation because of the dangers of a malignant degeneration in the cervical stump or the recurrence of carcinoma, which possibly might have been a coincident part of the fibroid, but been overlooked, was a strong one. In the event of carcinoma being present in an early stage in the fundus, its extension to the cervix was practically always by continuity along the line of the mucous membrane. He was sure, therefore, that the dangers of a malignant degeneration of the stump would be obviated by a thorough cauterization of the cervical canal either with the Paquelin or the electric cautery. This left only the rim of the cervix behind, but did not break the attachment of the broad ligament on either side. With this precaution, Dr. Clark believed it safe to advocate the retention of the cervical stump. Concerning the second point, for ten years he had followed the fixed policy of leaving behind the ovaries in every case of fibroid tumor where it was possible, and he had been astonished to find that this could be done in a large proportion of cases. Taking into consideration that the pathological findings bearing upon the association of ovarian disease with fibroid tumors largely consisted of various degrees of inflammatory lesions, he believed one was justified even when there were adhesions in leaving behind all or a portion of one or both ovaries; for in a considerable proportion of those inflammatory cases adhesions were not due to infection, but to traumatism produced by rubbing of the tumor against the ovary or crowding the ovary in against the pelvic wall or downward into Douglas's cul-de-sac. Therefore, he was sure that if this was relieved by the removal of the tumor, the ovary would not subsequently give rise to any serious trouble. As yet he had not made a postoperative study of these cases relative to the question of the surgical menopause, but he had had so many patients tell him that they were almost free of the distressing sequelæ of which others frequently complained that he was persuaded that this was the better policy to pursue. He stated, however, that this belief was based only upon a general observation, and not drawn from a minute analysis of his cases. Before any one could speak with certainty it would be necessary to analyze the cases at least a year subsequent to the operation. Until he saw some very definite reason, gained from such a study, to change the policy which he was now pursuing, he felt that he was distinctly serving the interests of his patients in conserving the ovaries. Relative to the third point, he was of the opinion, from the study of a large series of cases, that this complication was less frequent in this country than in Germany. The German gynecologists seemed to be greatly impressed with the frequency of the so called "myoma heart," and warned their students especially against the dangers of sudden death incident to heart disease following hysterectomy for fibroid tumors. Whether there was a distinct influence exercised by a fibroid tumor in producing heart trouble, he was unable to say, but he could not conceive of any more radical dis-

turbance being caused than that of a heart overworked in pumping blood through the resistant tumor mass. In a short experience in Prague he saw two fatal instances of pulmonary embolus, one of which was diagnosed as death from a "fibroid heart." In both cases autopsy showed that the heart was not at fault, but that an embolus had been detached from the seat of operation and had blocked up the pulmonary vessels, thus producing death. Therefore, in neither of these cases of sudden death could the action of the heart be called in question. Dr. Clark believed that a pulmonary embolus was much more likely to be a sequel of a hysterectomy for fibroid tumor than of almost any other pelvic operation, because the impaction of the tumor in the pelvis or its pressure upon the large vessels at the brim of the pelvis was very likely to weaken their walls and cause more or less dilatation. Not only might these vessels be the seat of a thrombus, but the greatly enlarged ovarian and uterine veins might also be the seat of large thrombi, from which emboli may be dislodged and carried to the lungs. Therefore Dr. Clark was inclined to think that sudden death following hysterectomy was more frequently due to a pulmonary embolus than to cardiac disease per se.

Dr. W. EASTERLY ASHTON thought that every case of fibroid must rest upon its own merits, and that in determining the line of treatment each case must be specially studied. There should be taken into consideration (1) the mortality of major operations on uterine fibroid, (2) the danger of degenerations occurring, and (3) the social condition of the patient. Considering that the true mortality of hysterectomy was probably from five to eight per cent., when a woman came to a surgeon seeking relief from a fibroid tumor, it was a serious matter whether or not to advise an operation. On the other hand, the social condition of the patient was also to be considered. Women in the lower walks of life, who were obliged to labor for their living, could not endure the symptoms produced as well as women with plenty of money. If a tumor was causing but little trouble, with no pressure symptoms, and the patient was in fairly good condition, he did not advise an operation, but the patient should be seen frequently, and if the tumor began to grow, an operation should be advised without saying that it was taking on this or that degeneration.

The operation of myomectomy, he believed, had a very limited field, and he agreed with Dr. Montgomery that it was dangerous. He had done few operations of that class, because it never appealed to him. He believed that if he were to adopt the operation he would have a large mortality, as the spaces were not well filled up and the tissues were so bruised that a bad focus for infection was left.

Comparing panhysterectomy with supravaginal operation, Dr. Ashton believed that in all cases, except where infection or malignancy existed, the supravaginal operation was the one of election. Panhysterectomy shortened the vagina, the marital relations are interfered with, and the operation had a higher mortality.

Dr. WEBSTER said that it was Dr. Noble's work

which had made him study his cases carefully, and he believed that a great many others had been started on the right lines through Dr. Noble's initiative. He thought that in this country in the last few years the profession had been carried away by the brilliancy of those who had perfected the major operations, and that attention had been concentrated on mechanical problems. In the American Gynecological Society, for instance, a very considerable amount of attention had been given to what Dr. Webster called "carpenter work." It seems to him that much more could be done in this direction, but that there was a very great deal of careful work to be done in the direction of solving just such points as had been before the society during the evening. He had been interested particularly in the differences in opinion regarding myomectomy. He had had occasion to study German statistics of hysterectomy, both for fibroids and for carcinoma, and he was confident that the mortality reported was very considerably higher than it was in the hands of operators in this country, and the same was true of the mortality of myomectomy in Germany. He agreed to the remarks made concerning the risks of performing myomectomy under certain conditions, and said that in his paper he had tried to point out the limitations which had guided him. He excluded infective conditions of the mucosa of the uterus. He did not think one should fear the danger of closing the myomectomy incision with continuous catgut. He had never used any other method. He did not think that myomectomy should be performed where a very large incision or where much mutilation of the uterus was necessary. In his myomectomy cases he had rarely had to open the mucosa or to make very large incisions; in other words, the tumors had not been large. He agreed that it would not be wise to perform myomectomy where there were many tumors. In the two cases quoted by him, in which pregnancy took place, he was particularly requested to perform myomectomy. In one six tumors were removed by the abdominal method, and in the other, twelve or thirteen. Both were in doctors' wives, and pregnancy happened to follow at a later date. In neither of these cases were all the fibroids removed from the uterus, a number of very small ones being left untouched.

He did not see why there should be a larger mortality after abdominal myomectomy in selected cases than after supravaginal amputation or total extirpation. He had felt in reading Richelot's paper, in which he advocated total extirpation instead of supravaginal amputation on account of the occasional occurrence of malignancy in the cervix after the latter operation, that Richelot was exaggerating the importance of the latter condition. He thought that Dr. Noble's statistics were more important in indicating the performance of the complete operation for the occurrence of adenocarcinoma in the body of the fibrous uterus. He admitted that it was impossible in many cases to diagnose this condition before operation without curettage; and even with curettage the condition might not be recog-

nized, because the spot in which the malignancy existed might not be reached. Taking everything into consideration, he believed that the logical procedure was to do the complete operation in every case and to put out of consideration supravaginal amputation. He was very certain, however, that this procedure would not commend itself to the majority of operators, who would continue to take chances as regarded the sequelae.

He did not think that the mortality of the major operations in non-infective cases should be as large as eight or nine per cent. in the hands of expert operators. He believed that the percentage had fallen below this figure in this country in the last three or four years, and if Dr. Noble's statistics were correct, certainly the lives of women would be saved by carrying out these operations rather than by leaving the tumors untouched.

Regarding the surgical menopause, he had felt from his observation of the condition that the menopause symptoms were no worse, taking a large number of cases into consideration, after operation than they were in normal conditions, and he had felt that the phenomena were less marked and the health certainly better in those cases in which abnormal losses of blood were prevented. He had tried to make observations with regard to the differences between cases of uterine extirpation in which part or both of the ovaries were left and those in which the latter were removed, but he had been unable to form any accurate opinion on the subject.

Book Notices.

The Urine; and Clinical Chemistry of the Gastric Contents, the Common Poisons, and Milk. By J. W. HOLLAND, M. D., Professor of Medical Chemistry, Jefferson Medical College of Philadelphia. Seventh Edition, Revised and Enlarged. With 41 Illustrations. Philadelphia: P. Blakiston's Son & Co., 1904. Pp. 174. (\$1.00 net.)

This standard work is too well and favorably known to make any extended review necessary. It is particularly rich in convenient and practical methods for the examination of the urine, gastric contents, the common poisons, and milk. In point of practical usefulness to both medical students and practising physicians, Holland's little work holds a high place.

Studies from the Department of Neurology. Publications of Cornell University Medical College. Vol. I. Pp. 239. New York, 1904.

This volume includes interesting descriptions of the formal (conventional) treatment of epilepsy and of special exercises for tabes dorsalis, for Parkinson's disease, and for aphasia, by Dr. Charles L. Dana; and accounts of a case of juvenile apoplexy in a man aged twenty-one, of a case of tumor of the right frontal lobe, and of a case of middorsal Pott's disease with compression myelitis, by Dr. J. Ramsay Hunt.

There are reprints of articles from various journals by Dr. Dana, Dr. Hunt, and Dr. Joseph Fraenkel. The volume is a very creditable evidence of the careful use of clinical material by the Department of Neurology of Cornell University Medical College.

Miscellany.

Sterility Caused by the Use of the X Ray.—The *Journal of Cutaneous Diseases* for March states that in its February, 1904, issue the experiments of Albers Schönberg were referred to as a warning of the danger of producing sterility incurred by x raying the testicles in a case of psoriasis presented by the writer before the December, 1903, meeting of the New York Dermatological Society. At that time it was asserted that the x ray was too powerful an agent to be used in the treatment of an affection which yielded readily enough to much milder remedies, especially when the disfiguring loss of hair and the unknown danger of causing necrostermia were to be considered. This patient was x rayed for lesions on the scrotum for twenty-five sances of five to eight minutes, or a total exposure of one hundred and twenty-five to two hundred minutes, and at present, or fifteen months since stopping treatment, has complete azoospermia.

This latter danger, in a much more insidious form, has been realized in the cases recently reported by Dr. F. Tilden Brown. Dr. Brown has made the unfortunate discovery that patients and physicians who had spent more or less time in an x ray atmosphere were the subjects of an azoospermia without being conscious in any way of deterioration or change in their potency.

The *Medical News* and the *Medical Record*¹ have already sounded the warning note in editorials, and have alluded to the experiments of Halberstädter (*Berliner klin. Wochens.*, January 16, 1905), showing that marked macroscopic and microscopic changes took place in the ovaries of rabbits which had been exposed to the Röntgen ray. "The histological change most in evidence was the complete disappearance of the Graafian follicles, in about fifteen days. Whether this loss is permanent and whether or not regeneration can take place, has not yet been determined. It was also found that the ovaries seemed more sensitive to the effects of the rays than the outer skin of the abdomen, and when compared with control experiments in male rabbits, developed degenerative changes in shorter time and with fewer exposures. How far these observations in animals apply to human beings cannot yet be definitely stated, nor is it known how permanent the effect may be." Of course, the question of individual susceptibility must also be taken into account, but since the wearing of an apron impervious to the rays, or the incasing of the focus tube so as to prevent the escape of all rays except those intended for a particular region under treatment, and avoidance of applying the rays to "danger zones," would seem to obviate all danger in this direction.

¹ See also this *Journal* for February 18, 1905, page 345.

Official News.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ending March 10, 1905:

Smallpox—United States.				
Places.	Date.	Cases.	Deaths.	
California—Los Angeles.....	Feb. 18-25.....	2		
California—San Francisco.....	Feb. 18-25.....	2

Public Health and Marine Hospital Service:

List of the Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending March 8, 1905:

ACHENBACH, JOHN, Pharmacist. Granted leave of absence for three days from February 26, 1905, under paragraph 210 of the regulations. Granted leave of absence for seven days from March 3, 1905, under paragraph 210 of the regulations.

BILLINGS, W. C., Passed Assistant Surgeon. Granted leave of absence for fourteen days from March 3rd.

FRANCIS, EDWARD, Assistant Surgeon. Granted leave of absence for seven days from March 6, 1905, under paragraph 191 of the regulations.

GRUBBS, S. B., Passed Assistant Surgeon. Granted leave of absence for two days from March 7th

- KEATLEY, H. W., Acting Assistant Surgeon. Granted leave of absence for four days from March 1, 1905, under paragraph 210 of the regulations.
- LOPEZ, ESTEBAN, Acting Assistant Surgeon. Granted leave of absence for thirty days from January 1st. Granted leave of absence for five days from January 31, 1905, on account of sickness.
- MCLAUGHLIN, A. J., Assistant Surgeon. Granted leave of absence for six days from March 6th.
- ROSSELLO, M. M., Acting Assistant Surgeon. Granted leave of absence for seven days from February 18, 1905, under paragraph 210 of the regulations.
- STEVENSON, J. W., Acting Assistant Surgeon. Leave of absence for seven days from February 27, 1905, granted Acting Assistant Surgeon Stevenson, revoked. March 8, 1905.

Boards Convened.

Board convened to meet at Washington, D. C., March 10, 1905, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board—Assistant Surgeon General G. T. VAUGHAN, chairman. Assistant Surgeon H. McG. ROBERTSON, recorder.

Board convened to meet at San Francisco, Cal., April 3, 1905, for the examination of assistant surgeons to determine their fitness for promotion to the grade of passed assistant surgeon. Detail for the board—Passed Assistant Surgeon RUPERT BLUE, chairman. Passed Assistant Surgeon H. S. CUMMING. Passed Assistant Surgeon D. H. CURRIE, recorder.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the two weeks ending March 11, 1905

- BACHMANN, R. A., Assistant Surgeon. Detached from the *Wilmingon* and ordered to the *Villalobos*.
- BENTON, F. L., Passed Assistant Surgeon. Ordered to the Naval Recruiting Station, Philadelphia, Pa.
- COOKE, G. H., Medical Director, retired. Detached from the Naval Recruiting Station, Philadelphia, Pa., and ordered home.
- DE LANEY, C. H., Passed Assistant Surgeon. Detached from the *Petrel* and ordered to the *Marblehead*.
- HUNTINGTON, W. H., Pharmacist, retired. Ordered to the Naval Training Station, Newport, R. I.
- KERR, D. B., Passed Assistant Surgeon. Detached from the *Buffalo* and ordered to the *Boston*.
- MANCHESTER, J. D., Assistant Surgeon. Detached from the *Marblehead* and ordered to the *Petrel*.
- MILLER, J., JR., Assistant Surgeon. Detached from the *Boston* and ordered to the *Buffalo*.
- MICHEL, R. H., Assistant Surgeon. Detached from the *Villalobos* and ordered to the *Wilmingon*.
- RODMAN, S. S., Passed Assistant Surgeon. Detached from the *Pensacola* and ordered to the *Ranger*.
- TAYLOR, E. C., Assistant Surgeon. Detached from the *Bancroft* and ordered to the *Colorado*.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending March 11, 1905:

- DEAN, ELMER A., First Lieutenant and Assistant Surgeon. Left Fort Riley, Kan., on March 3, 1905, on ten days' leave of absence.
- DE LOFFRE, SAMUEL M., First Lieutenant and Assistant Surgeon. Granted thirty days' leave of absence from March 8, 1905.
- HOFF, JOHN VAN R., Colonel and Assistant Surgeon General. Granted thirty days' leave of absence.
- JONES, PERCY L., First Lieutenant and Assistant Surgeon. Reported on March 4, 1905, for temporary duty at Washington Barracks, D. C.
- MORSE, A. W., First Lieutenant and Assistant Surgeon. Granted thirty days' leave of absence, to take effect on or about February 27, 1905.

PORTER, R. S., First Lieutenant and Assistant Surgeon. Left Fort Niobrara, Neb., on March 4, 1905, on ten days' leave of absence.

RENO, WILLIAM W., First Lieutenant and Assistant Surgeon. Left Fort Myer, Va., on March 8, 1905, for temporary duty as surgeon on the transport *Summer*.

SHILLOCK, PAUL, Major and Surgeon. Granted one month and fifteen days' leave of absence, to take effect on or about March 10, 1905.

Births, Marriages, and Deaths.

Married.

ALLEN—RUBEL.—In Louisville, Kentucky, on Wednesday, March 1st, Dr. M. K. Allen and Miss Jessie M. Rubel.

BIRD—GILLETTE.—In New York, on Tuesday, March 7th, Mr. Harrison Kett Bird and Miss Grace Gillette, daughter of Dr. Walter R. Gillette.

CHITTENDEN—BEEBE.—In New York, on Thursday, February 23rd, Dr. Arthur Smith Chittenden and Mrs. Anna Preston Beebe.

MENDE—PORTER.—In Paris, France, on Saturday, March 4th, Dr. Edwin Mende and Miss Elsie Porter.

SWAYNE—VODGES.—In Philadelphia, on Thursday, March 2nd, Dr. Horace R. Swayne and Miss Anna M. Vodges.

Died.

AMILON.—In Chicago, Illinois, on Wednesday, March 8th, Dr. Ivan C. Amilon, in the thirty-fourth year of his age.

CHRISTOPHER.—In Chicago, Illinois, on Thursday, March 2nd, Dr. W. S. Christopher, in the forty-sixth year of his age.

DINGMAN.—In Spring Valley, N. Y., on Saturday, February 25th, Dr. James Alva Dingman, in the fifty-seventh year of his age.

EDWARDS.—In West Plains, Missouri, on Thursday, March 2nd, Dr. W. T. Edwards.

ELLIS.—In Cincinnati, Ohio, on Thursday, March 2nd, Dr. Charles E. Ellis, in the fortieth year of his age.

FAHRNEY.—In Hagerstown, Maryland, on Sunday, March 5th, Dr. Daniel P. Fahrney, in the sixty-ninth year of his age.

FREED.—In Chambersburg, Pennsylvania, on Monday, February 27th, Dr. E. S. Freed.

HYSLOP.—In New York, on Saturday, February 25th, Dr. George Lederman Hyslop, in the eightieth year of his age.

JONES.—In Kansas City, Missouri, on Tuesday, February 28th, Dr. P. C. Jones, in the seventy-third year of his age.

LANGSON.—In Chadron, Nebraska, on Tuesday, February 28th, Dr. R. K. Langson, in the forty-fourth year of his age.

MEANS.—In Boston, Massachusetts, on Thursday, March 2nd, Dr. Andrew F. Means, in the sixty-seventh year of his age.

METCALF.—In Orvieto, Italy, on Wednesday, March 1st, Dr. George R. Metcalf, of St. Paul, in the fifty-eighth year of his age.

MILLS.—In Hume, N. Y., on Friday, February 10th, Dr. Julia A. Mills, in the eighty-sixth year of her age.

REYNOLDS.—In New York, on Saturday, March 4th, Dr. Warren O. Reynolds, in the fifty-seventh year of his age.

SHAW.—In Memphis, Tennessee, on Friday, March 3rd, Dr. Henry Jackson Shaw, in the eightieth year of his age.

SIM.—In Libertytown, Maryland, on Tuesday, February 28th, Dr. J. Thomas Sim, in the sixty-eighth year of his age.

TIERNY.—In Leominster, Massachusetts, on Tuesday, March 7th, Dr. Martin H. Tierney, in the forty-sixth year of his age.

ZIPPERLEN.—In Cincinnati, Ohio, on Tuesday, February 28th, Dr. Adolph Zipperlen, in the eighty-eighth year of his age.

Lectures and Addresses.

MEDICAL PROGRESS.*

By J. A. WRIGHT, M. D.,

TOLEDO, O.

When we remark that medicine has made stupendous progress during recent years, we recognize a somewhat hackneyed expression, but one which will bear occasional repetition. Almost within the last decade new discoveries and changed theories have revolutionized our methods of diagnosis and treatment, if they have not actually resystematized the practice of medicine. Some of these changes have been most startling and radical and have so completely overturned our previous conception of things that the graduate of twenty years ago, who stood still and failed to keep up with the rushing trend of medical thought, would be as much lost in modern practice to-day as a South Sea Islander suddenly transported to the best drawing rooms of New York or Paris.

It would seem reasonable to expect that this sort of thing ought to stop sometime, somewhere, but we can gather assurance from the hurrying activity to be seen in every department of medicine and the ceaseless suggestions of progress along the lines of professional action from skilled toilers in our many fields, that not only is the good work going bravely on and the end not yet in sight, but that never before in the history of the world has the tirelessly nimble medical mind toiled so incessantly, intelligently, and effectively as at the present time; never before has superbly trained and keenly alert scientific skill been so pregnant of expectant fruitfulness.

Surgery, the great leader of medical advance, still keeps on the even tenor of its way, making history as it goes; marking its step so clearly that, in retrospect, one can plainly note its course from point to point during its brief but eventful modern era and marvel as well at its stupendous progress as at the dazzling possibilities of the future. Some one says "the supreme test of true progress is ever results." Judged

by this standard surgery, of all departments in medicine, is entitled to the victor's palm, for the steadily decreasing rate of mortality following abdominal sections and capital operations generally shows such phenomenal results, as compared with those following earlier efforts, that the greatly enhanced value of present method is distinctly apparent. Technique, preparatory and operative, to an onlooker seems well nigh perfect and it might be passing difficult to suggest in what way improvement could be made in this direction.

Of the many noteworthy advances in this branch it may be invidious to dwell on any specifically, but I cannot refrain from mentioning the procedure advocated by Dr. G. W. Crile of injecting cocaine solution into large nerve trunks immediately above the seat of contemplated operation. This method, technically called nerve blocking, has shown itself plainly efficacious in preventing the occurrence of shock and thus obviating a very grave danger in many operations.

That the use of cocaine as suggested would relieve pain was to be expected, and we know that, as an efficient anæsthetic, it has been very often injected into accessible tissues and within the spinal canal, but that arrest of sensation, in this manner, means also the prevention of shock is a revelation which, apart from its eminently practical value, proves very plainly that shock is of purely nervous origin; that it is not due, for instance, to hæmorrhage or exsanguination, which produces serious enough consequences indeed, but which ought to be called by its proper name. Incidentally, it opens up interesting speculation as to the relationship of pain and shock, which could be dwelt on with profit if it was not clear digression.

No better illustration of the hurrying rapidity of medical progress—which effects almost incredible ends and almost forgets them in the absorbing race to further conquest—can be given than to call attention to the fact that the transcendent story of the x ray is already old.

Only a few years ago the world was astounded when announcement was made that by means of Röntgen's discovery the hidden structures of the

* President's Annual Address, delivered before the Toledo, O., Academy of Medicine.

body could be visually perceived. This, surely, was startling and revolutionary. More than that it was in utter conflict with scientific dogma—with what was thought to be known of the very laws of nature—and, during all preceding ages, no one but the writers of whimsical fairy tales even dreamed of looking into and beyond structures completely impervious to brightest known rays of light. But now, how commonplace! Everywhere the progressive medical man demonstrates, with what may be rightly termed true clairvoyance, the processes of disease and deformity; the plain evidence of fracture and injury; the visible presence of deeply buried bullet and calculus.

Supplementary to this epoch-making discovery and almost obscuring it in importance, it was found that structural changes were effected by x ray exposure, and, by logical deduction, there has been evolved an essentially scientific scheme of treatment as the result of which previously intractable, incurable, malignant, and fatal diseases have been made to loosen their almost relentless hold on humanity. One of the nicest consequences of the use of this efficient therapeutic force is that the ultra modern surgeon no longer dreads, as before, recurrence of malignant processes after operation, for it has been proven beyond cavil that x ray exposure can, in many cases, prevent this heretofore irremediable disaster and save the sufferer from its otherwise inevitably fatal results.

Fluoroscopy, radiography, and radiotherapy have thus achieved definite, well established, and indisputable position as invaluable if not indispensable means of diagnosis and easily available methods of conquering many previously unconquerable conditions.

In allied departments of electrotherapy the forward movement has been steady and strong, and the present day sees static electricity, freed from the shackles of empiricism, occupying a deservedly high place as an effective remedial agent in a large number of peculiarly troublesome and very obstinate complaints. This form of electricity, with its intensified and powerful coefficient, the high frequency current, if not actually supplanting the so called orthodox methods of treatment, in many cases brings to their support such correction of faulty nerve force, stimulation of metabolism, and fortification of resistance that the period of disability is often greatly shortened and prompter restoration to health and strength reasonably assured.

Few branches exhibit greater signs of activity and reawakening interest than preventive medicine, but though much has been recently accomplished in this field, it is largely of indeterminate character and certainly very much more remains to be done.

The term implies concerted effort on the part of

physicians to guard humanity against the recognizable and preventable causes of disease and death, and this fully typifies the purest and highest conception of the true, altruistic aim of the profession. To shallow minds it may seem passing strange that an intelligent body of mortals would seriously endeavor to limit its business opportunities and curtail its own material revenue—and this is plainly what preventive medicine aims to accomplish—but, to the true physician, thoroughly imbued with the unselfish spirit of a vocation essentially unselfish, there is nothing that appeals more powerfully than a good chance to strangle in its incipency a menacing danger to life and health, which, if allowed to grow to maturity, will develop such strength and spread such disaster that the most strenuous and heroic efforts to conquer it must often prove futile.

If ætiological factors can be destroyed or avoided, it follows that the individual is not only protected but that the generation of countless microorganisms—the beginners of disease—whose mere existence is fraught with danger and death, is absolutely prevented. It has been stated by high authority that “five out of every ten diseases most widespread and fatal are due to the operation of causes fully recognizable and completely preventable.” If this is so—I do not know that it is even questioned—what grand results would follow a perfectly organized system of preventive medicine. If the good work was limited to tuberculosis alone—the great white plague with its annual death toll in the United States alone of nearly 150,000—what an immense triumph it would be to reduce by a large percentage its present frightful fatality. This is not only possible but practicable. Then we have pneumonia, next in order to tuberculosis as a death producing disease, with a recognized pathogenic bacterium; typhoid fever also, the prevention of which is definitely understood, and of which it has been well said that “every case is the result of criminal ignorance or of still more criminal negligence.”

With clear recognition of the causes of disease and definite understanding of means to make them inoperable, it seems a sad commentary on our boasted progress that according to good authority, “the sun shines daily on thousands of perambulating incubators of death and disease, each one of whom, during the hours of daylight, distributes enough germs about him to infect every man, woman, and child in the republic.” Still this neglect is more apparent than real, for, after all, we have knowledge important and primarily essential to accomplishment. All that is now needed is the perfection of methodical plans which can be carried out systematically and in concert by the whole profession, and thus will the evolution of preventive medicine be ultimately effected.

The growing interest in preventive medicine should be hailed, nourished, and stimulated by medical men and medical organizations everywhere as one of the most hopeful signs of impending brilliant achievement. While the field is wide, the soil is fertile and opportunity for success large and promising. It should never be forgotten that one of medicine's greatest triumphs was accomplished in this field, and who can tell, with the vastly superior power and advantage conferred by modern science, what names the future may not find inscribed on the roll headed by that of the immortal Jenner.

Did I say immortal? It is all too feeble a term. Did you ever think of the millions of cases of loathsome disease that Jenner's discovery has prevented? Think of the many thousands whose lives he must have saved since the first vaccination in 1796; think of the good work still going on, with vaccination firmly established and compulsory in every civilized nation under the sun; think of the myriads yet unborn, to be shielded from pestilence and death by its employment continued, as it must be, through coming ages as long as time endures, and realize, if you can, the immensity of a pyramidal monument that might be constructed to his memory, if every life saved and to be saved was represented by a single stone. Such a structure would, by comparison, make the great pyramid of Cheops look like an ant hill, and it would be but commensurate with the work of Jenner.

More real good to humanity than the accomplishment of any king, ruler, statesman, or potentate who ever lived has resulted from this single exploit of preventive medicine, and the time is surely ripe for other death dealing diseases to find their capacity for harm practically obliterated, as that of smallpox has been, by definite immunizing protection.

Materia medica alone, of all departments in medicine, has occupied an unenviable position in recent years. It seems as if pathology and diagnosis have so completely engaged the attention of workers in general medicine and have demanded such stress of energy that effort in at least an equally important direction is impossible. Not only this, it has become a decided fashion to belittle curative medication, many of the assumed leaders and some of the noted authorities tacitly uniting in what has been aptly termed a crusade of therapeutic nihilism. The result of this movement is just what might have been anticipated. Drugs are neglected if not derided, and the latter day product of the schools, though well equipped to make skillful diagnosis, is left helpless in the highest motif of the physician, the restoration of health.

To fit this unwholesome condition a new word has been coined and the therapist is now apologetically dubbed an internist. To me the term has an

offensive ring. Coming as it usually does from some ambitious surgical tyro, who, as he recounts often uncalled for if not questionable operations, mouths the word as though he found it sweet and as if he felt that it marked an insuperable chasm between the homely work of the general practitioner and his own more spectacular performances.

The scope of the general physician is wide, deep, and extensive. He must know and be able to recognize, almost by intuition, the multifold morbid activities that characterize innumerable ills; to discriminate at once as to the exact significance of symptoms presented; to estimate accurately the injury resulting from and the continuing effects of morbid influences; to perceive clearly the coming consequences of persistent pathological processes; to weigh delicately the relative power of resistance of ever varying constitutional individuality to ever differing intensity and always greatly modified types of sickness; as a wise general, to know the tactics of the enemy, and so to conserve the forces of nerve and blood and brain and life, that all may be so fortified against anticipated encounter with formidable reserves and allies of the enemy that the citadel, in time of danger, will be found impregnable. In addition to this and much more, he must have an intimate, comprehensive, accurately tabulated, and instantly available knowledge of therapeutic values; and when we know—as we must if properly informed—that the resources of material medicine are not narrow but practically limitless, some conception may be had of the mere intellectual horizon of the qualified therapist. If possessed of a busy practice, he must be vigilant, tireless, and sleepless, toiling with unfaltering energy by day and by night, in season and out of season; cold, wet, exhausted, and yet with supreme determination taking from the few short hours of needed rest the time required for necessarily strained and highly concentrated studious effort. The ground is vast, but he must cover it all.

Can human frame and mortal strength endure such strain and live? It can betimes, but think you not, O thoughtless critic, if one survive training like to this, he is not made, morally, physically, and intellectually, vastly greater and stronger? Let me give voice to long held conviction: The capable, extensive, conscientious, general practice of medicine either kills a man or moulds a giant.

As well call the competent surgeon an externalist or superficialist as use a word of like restricted meaning to designate the hardest, most deserving worker in the most expanded field of medicine, the greatest and most versatile of specialists, the general practitioner.

I have dwelt on this point to give timely and needed hint of an insufferable situation which calls for

redress, as well as strenuously to controvert the tendency of recent writers, on almost every morbid condition, to place the physician powerless in the presence of disease. Therapy is the very keystone of regular medicine. The only thing that marks definite and distinct separation from the irregulars. Better surrender your entire system of medicine if you cannot attack and overcome the enemy it is your special province to fight.

Talk, as you do, of the uselessness of medicine in typhoid fever and pneumonia, at every point in all stages of these diseases distinct and clearly defined internal medication is indicated. Its competent and intelligent employment will shorten the course, ameliorate unfavorable conditions, lessen suffering, and curtail mortality, pessimistic authority to the contrary notwithstanding. Let those who proclaim helplessness call themselves pathologists, hematologists, diagnosticians, or nurses, they are not physicians in the properly accepted meaning of the term.

The physician should heal the sick as well as know disease.

Along the line of *materia medica* perhaps the most startling and widely resented innovation on time honored methods and dogmas is what may be euphemistically termed the assault on strychnine. For scores of years strychnine has been regarded as an absolutely certain and reliable stimulant to the respiratory centre, also to the heart and vasomotor centres. According to every authority, under its influence the indispensable functions innervated by those centres were not only conserved and strengthened, but those of the spinal cord exalted and stimulated. Above all it was asserted to be supremely useful and wonderfully effective in overcoming all kinds of shock, surgical or otherwise, and that it could be particularly relied upon to increase and maintain arterial pressure.

Now comes Dr. Crile, one of the most patient, capable, and thorough of laboratory investigators, who, from a long series of critical, painstaking, and seemingly complete experimental studies, has proved, to his satisfaction and that of others, that this generally employed and time tested reliance is not to be depended upon, that it is not only useless but injurious and that, in its most valued applications—the relief of shock and the maintenance of blood pressure—it actually contributes to the very ends we aim to avert.

While too much credit cannot be given the doctor for his able and original work, and while his deductions should be accepted as food for deep and careful thought, yet we should remember that his investigations were conducted on the dog, an animal known to be especially susceptible to the toxic effects of strychnine, and we should also cautiously consider that laboratory finding is not by any means

always verified in clinical results. Still, a critical study of the series of tests reported should at least make us carefully observant and watchful to the end that this still mooted and highly important question be definitely settled.

If strychnine is to be displaced as an eligible remedy for shock, we may perhaps use it in other directions. It is said to stimulate the appetite for food, and to encourage other appetites, but it looks very much as if the authorities in *materia medica*, who have been getting pretty hard knocks in this and other matters, will soon have to carefully revise their treatises. After all, they are no worse off than our chemists, who, as a result of the discovery of radium and radioactive compounds, feel that the very foundation of present day chemical science, the atomic theory, is tottering to its fall.

Speaking of radium, it is rather unfortunate that this wonder working element has been exploited to its injury by the sensational press and the equally sensational but more mendacious charlatan. Apart from its phenomenal emanations of heat, light, and force that produces fluorescence, it effects structural changes in tissue, as does the x ray, but its action is feeble, exposure must be by close contact and, so far as can easily be discovered, it cannot be classed as an efficient curative agent in the cases to which the x ray is so effectively applicable. The London Hospital, after thorough, rigid, and wholly unprejudiced investigation, reports that its availability as a therapeutic agent has not been plainly established. I have personally investigated some of the startling newspaper cures of malignant diseases—where addresses were given—and was not surprised to learn, in every instance, that no such favorable result had been accomplished.

The internal administration of fluids made radioactive through the intervention of this element is based upon visionary hypothesis and, to put it mildly, is utterly empirical.

Radioactivity is a new and entrancing field of study. Beginning with the introduction of the x ray, nine years ago, followed by the discovery of the radioactive properties of uranium by Becquerel, in 1897, the later announcement that thorium, polonium, and other elements had similar properties, and the more recent, culminating discovery of radium, it has thrown the scientific world almost into a state of revolution. Largely from a consideration of this new demonstration of force, Sir Oliver Lodge asserts positively that matter is electricity and nothing else. Sir William Ramsay, a scientist whose conservatism and precision of statement are characteristic, says "it looks probable that atoms are not indivisible, but are disintegrated and reconstructed and that, in consequence, the transmutation of elements is no longer an idle dream."

The whole quantity of radium yet produced is exceedingly small, somewhere about forty grains, and when one thinks of the many thousands of specimens distributed throughout the world, most of them consisting only of the minutest fragments of fractions of molecules, not even of radium, but of some compound of radium, it leads quite naturally to the query: Which is the more gullible, the purchasers of these really typical homœopathic attenuations or the dear public upon and before which its wondrous curative properties are exploited?

The ancient branch of obstetrics has been justly called the parent of medical craft. It has been practised in a manner for many thousands of years, and one can easily go back in imagination to primeval times and realize that even then the pangs and dangers of childbirth must have evoked the best sympathy and most helpful assistance that the rude age afforded. The evolution of obstetrics, therefore, has been a long process. Unlike gynecology, which has been wonderfully developed in the last twenty-five years, obstetrics has been slowly growing for centuries. It is not then to be expected that as much recent progress should be had in this long practised art as if it were new in origin. Consequently, save that it has benefited in the general adoption of antiseptic and aseptic methods, and improved the means of forceps delivery, advance has until very recently not been noticeable. Within the past year or two, however, this department seems to have awakened to a sense of the activity everywhere else manifested and has made some creditable efforts to show that the last word has not been spoken even on the time honored, long practised science and art of obstetrics, and that works on this subject may have to be rewritten.

One of these advancing steps is the devisement by Gigli of extramedian symphyseotomy, by means of which the capacity of contracted and distorted pelvis is greatly increased and delivery at full term rendered safe and easy. The operation, which is devoid of danger, has been further improved in technique by Döderlein and employed by him and others in a considerable number of cases with marked and gratifying success.

Another more original and strongly progressive movement is the suggestion of spinal cocainization to effect painless parturition in normal labor.

Notwithstanding the biblical decree that women must bring forth offspring in anguish, it has ever been the dream of the accoucheur to obviate this condition. To this end general anæsthesia has been successfully employed, but its use has not been commonly established nor has it, for various reasons, been considered an unmixed blessing. A radical change in the conduct of labor is now proposed by Dr. Biers and Dr. Donitz, who have, for some time past, been

demonstrating that spinal anæsthesia with cocaine will entirely remove the suffering without destroying consciousness or interrupting the safe progress of labor. They have interested obstetricians generally in their highly successful efforts and others have been following the work with equally satisfactory results.

Dr. Martin, who has made use of this mode of anæsthesia in a series of thirty cases of delivery in healthy women at full term, endorses it unequivocally. He says, in a recent number of the *Journal of the American Medical Association*, "the anæsthesia is perfect and lasts from one hour to an hour and a half. If delivery occurs during this period the complete absence of pain during the entire process of parturition is most remarkable. Uterine contractions do not seem to be interfered with, but the expulsion of the child proceeds more slowly. Involution, lactation, and the progress of puerperal convalescence are not disturbed in any way."

The slight retardation noted by the doctor is very likely due to the reduction of voluntary muscular effort. To me this seems a positive benefit, as this violent and wholly unnecessary exertion not only exhausts the strength of the subject, but is also an important factor in causing lacerations.

It will readily be seen that the use of this method need not be restricted to normal labor, for with it the forceps ought to be easily employed, and every operative procedure associated with delivery, from version to repair of the perinæum painlessly effected.

Still another thought: If injection of cocaine solution into nerve trunks prevents shock, its effect on the spinal cord must certainly produce a like result and, in difficult labors, shock is certainly one of the serious dangers to be reckoned with and obviated if possible.

Work of this character is not simply speculative and interesting, but of the very highest practical value. If it is true that with this method there is little danger of untoward effects and that the results of its more general employment will be as satisfactory as the reports received positively indicate, it would seem not only advisable but imperative that the really progressive obstetrician equip himself for that which offers to be a realization of a long cherished ideal, the consummation of painless parturition.

In an address of this kind it is inevitable that many of the recent advances in medicine cannot be enumerated, and that those which have been mentioned cannot be considered in that fine detail their merits deserve; still enough has been said to show in a general way that, notwithstanding the progress which has been made, the real force of the movement has scarcely begun. It may in truth be likened

to an avalanche that starting slowly from the top of a high mountain gathers volume and energy as it moves on until, with resistless force and weight and speed, it sweeps away the barriers of brush and debris, obstructions of earth and stone, and opens up a fair wide vista from the valley below to the summit above the clouds.

What has been said of the sluggard graduate of twenty years ago is doubly true of the graduate of yesterday. No matter how well equipped in present day methods, if foolishly deaf to the echoing note of progress; if wilfully blind to the glowing signs of greater scientific advance, he, in far briefer space than his prototype, will be relegated to the distant rear, a crippled soldier left behind by the rapidly marching army, a lumbering craft beyond hailing distance of the fast disappearing fleet.

1822 CHERRY STREET.

Original Communications.

THE INFLUENCE OF INFECTED MILK IN THE DIET OF THE SICK—PARTICULARLY IN ACUTE INFECTIOUS DISEASES. WITH A REPORT OF A SERIES OF CASES OF MILK INFECTIONS IN TYPHOID FEVER PATIENTS.*

By DAVID L. EDSALL, M. D.,
PHILADELPHIA.

The enormous importance of infected milk in the production of digestive disturbances in infants has for years been clearly demonstrated and generally recognized, and energetic efforts are now being made everywhere to control the infant mortality by giving babies clean or Pasteurized milk only. The profession is also alive to the fact that tuberculosis, typhoid fever, diphtheria, and a number of other infectious diseases (probably most of those that are of bacterial origin, and perhaps some that are parasitic) may be transmitted through milk, and that some of these diseases certainly have been frequently so transmitted. It is also well known that typhoid fever, diphtheria, probably scarlet fever, and also other specific infectious diseases, have often flourished in epidemic form as the result of specific infection of milk. There are, furthermore, a number of striking instances on record of epidemics in which there were clearly marked clinical symptoms, but which were not due to any known specific infection, and these have been traced with great clearness to the milk supplied to the patients. Cases of this sort have occurred in both

adults and children; and the symptoms have been chiefly sore throat or gastrointestinal disturbance, together, usually, with fever and more or less severe constitutional symptoms. Cases more or less closely resembling those in the epidemics last mentioned, but occurring in small numbers in a household or singly, are, of course, occasionally seen by any careful observer and found to be probably due to the milk used; at times, indeed, they have been pretty clearly shown to be milk infections.

The types that have been mentioned are the chief forms of infection that are known to be produced by milk. In addition to these, it is recognized that milk may be the cause of toxic symptoms that are sometimes exceedingly violent and are not directly due to the bacteria present, but to poisonous substances produced by these bacteria.

All these are widely known possibilities; and if any of these infections or poisonings occurs, the attending physician, if he is alert, will attempt, among other things, to determine whether the milk is at fault. There is still another group of cases, however, in which the effects of bad milk are, I am sure, very often overlooked, chiefly because they are rendered obscure by other factors that are present. I mean those cases (occurring principally in persons on milk diet and especially in those with acute infectious diseases), in which symptoms are caused by the milk used in the diet, but in which these symptoms are not severe enough to arouse readily a suspicion as to their source; and in which similar symptoms may be and often are produced by the disease for which the patient is being treated. In other words, I mean cases in which the milk does not itself produce grave and evident infection, but in which it succeeds in making worse a disease that is already more or less bad; and in which the symptoms are likely to be attributed to the disease rather than to the food. That this occurs with some frequency has been generally believed by those interested in milk infections; but it is almost always a difficult point to prove, and there are, so far as I am aware, no clear records in medical literature of cases in which there has been any extensive evidence of its occurrence.

That it does occur and may be of much importance, is shown by the conditions that I am about to describe, which are conspicuous in that it was possible to demonstrate the facts with much comprehensiveness, and in that the series of cases observed was large. When I went on duty in the men's wards at the Episcopal Hospital on April 1, 1903, there were twenty-eight cases of typhoid

* Read by invitation before the Medical and Surgical Society of the District of Columbia, Washington.

fever in the acute wards. Sixteen of these patients were in the active stage of the disease; twelve were in the late decline or were convalescent. I was much impressed by the fact that six of the sixteen acutely ill patients had persistent diarrhoea which had resisted ordinary treatment; and that scarcely a patient in the wards was requiring enemas frequently—almost all having one to three spontaneous, and often loose stools, daily, while the six with decided diarrhoea were having from three to ten daily. Dr. D. J. Milton Miller, who had served the preceding four months in the same wards, remarked upon the recent persistence and frequency of diarrhoea in the typhoid cases and said that he believed the milk to be responsible for it; a suggestion that met the same thought in my own mind. It is my experience and, I think, that of most other observers, that typhoid patients, when well cared for and properly fed, require enemas in a decided majority of cases; and that very few have troublesome diarrhoea. More or less marked looseness of the bowels is common when cases are first seen and for a few days thereafter; but this is almost always due to previous bad feeding, and quickly responds to care in the diet, especially to a reduced amount of food. Severe diarrhoea is, of course, not a normal symptom of well managed typhoid fever, but is always an unfortunate complication; and even moderately marked diarrhoea is exceptional and is to be considered a complication, rather than a part of the disease. It is always an undesirable complication, for it is likely to be associated with distention and not infrequently, with abdominal pain, gastric disturbance, and decided evidences of toxæmia; and at best, it is likely to increase the prostration and the tendency to hæmorrhage and perforation.

In the patients under discussion, not only was intestinal disturbance from slight looseness of the bowels up to severe diarrhoea almost the rule rather than the exception, but other abdominal symptoms were also marked and common. Five of the patients complained within the next few days of attacks of colicky pain; a number showed decided distention; and several were nauseated. The typhoid cases also seemed more seriously ill than is common in an equal series of cases and abdominal symptoms other than diarrhoea occupied a conspicuous place in the picture in so many cases as to lead me to discuss the cause of it repeatedly with Dr. Harrar, who was then my resident. I had never seen this class of symptoms so prominent in such a large group of cases.

It is also worthy of mention, as not improbably related to this question, that four patients had dangerous hæmorrhage in the early part of

April; and that three others during this time had moderate hæmorrhage.

After having observed these conditions for several days and finding them persistent, I asked Dr. Ghriskey to make a count of the bacteria in the milk. I examined it chemically, and found 3.6 per cent. of fat, 3.45 per cent. of proteid, and no preservatives; in other words, the chemical conditions were entirely satisfactory. Four days later, Dr. Ghriskey reported to me that he had plated several specimens of the milk, and that in all he had found the bacteria uncountable after twenty-four hours in a 1 to 10 dilution; the number, therefore, being at least several millions.

These examinations were repeated several times, in order that we might be sure of our facts before giving troublesome orders; all the cases with severe diarrhoea being, however, for the time, put on liquids other than milk. The diarrhoea in the latter cases gradually ceased and at the end of five or six days, all were having but one or two stools a day. In the meanwhile, Dr. Ghriskey's bacterial counts were carried out; and each showed a very excessive number of bacteria. One showed only 200,000, all the others millions. These figures, conclusive enough at any time, were all the more so in this instance, since it was cool weather.

On the ground of these results, I gave an order that all the patients in the ward receiving milk should have only Pasteurized milk, the Pasteurizing to be done as soon as the milk was delivered at the ward. The results were very striking. From April 15th, at which time Pasteurizing had been generally established, to August 1st, when my service ended, there were admitted to my wards ninety-two other cases of typhoid fever. Of these, eight had diarrhoea on admission. In five of these eight, it subsided in three or four days and the patients afterwards required enemas most of the time. The three others had severe abdominal symptoms when admitted, were much prostrated, and died within a few days from these causes. Only four patients developed diarrhoea when in the house. In three of these it was mild (three to five stools daily and soon subsiding); in the fourth, it was severe. The latter patient, however, died of hæmorrhage and the autopsy showed his colon to be riddled with ulcers. The local lesion, therefore, probably sufficed to explain the abdominal symptoms in his case. Of the remaining eighty patients, fourteen had usually one or two, occasionally three, spontaneous movements daily; some of the time requiring enemas. The sixty-six others required enemas most of the time, occasionally having one or two practically normal spontaneous move-

ments. If the five that had diarrhoea upon admission but soon required enemas, be added to the last mentioned group, seventy-one of ninety-two patients usually required enemas, fourteen had nearly normal spontaneous movements, three developed mild diarrhoea in the house and one developed serious diarrhoea in the house, the latter patient having extremely extensive ulceration of the lower bowel.

Contrast these conditions with those mentioned as having been present at the beginning of April, when there were twenty-eight typhoid patients in the ward, sixteen of whom were in the fastigium of the disease. Of the latter sixteen, six had serious diarrhoea, while none of the other ten required enemas and several of them had already been under treatment for troublesome diarrhoea. Of the twelve that were in convalescence or in the late decline of the disease, only three required enemas; three had mild diarrhoea; and the remaining six had spontaneous movements with an occasional day of loose movements.

An even more striking contrast is afforded by the records of the cases in the men's wards during February and March. Within these two months, forty-eight patients with typhoid fever were admitted to the men's wards. Two of these died within two days; and therefore I have excluded them from the statistics. Of the forty-six others, only nine required enemas; eight had one to three spontaneous movements daily; and twenty-nine had diarrhoea. Of these twenty-nine, twenty had from four to ten stools daily for from one to three weeks (in one case, five weeks); while in the remaining nine there were repeated transitory attacks of diarrhoea, lasting one to three days with four to six stools daily.

Put in the form of percentage, from April 15th to August 1st, of ninety-two patients, seventy-seven per cent. required frequent enemas and only four and three tenths per cent. developed diarrhoea in the house; from February 1st to April 1st, of forty-six patients, only 19.5 per cent. required frequent enemas, while sixty-three per cent. either developed troublesome diarrhoea in the house or persisted in having diarrhoea for a long time after admission. The only noteworthy difference in the management of these cases during the two periods consisted in the fact that from April 15th to August 1st the milk was Pasteurized, while during February and March it was not.

That the difference was not due to any conditions relating solely to the men's wards is also shown by contrasting the records in the women's wards during the month of March with those dur-

ing June, the milk served there having been Pasteurized during the latter month, but not in the former. During March, eighteen cases of typhoid fever were admitted to that ward. Of these only six required frequent enemas; three had from one to three spontaneous stools daily; one had diarrhoea on admission, which soon subsided; and eight had persistent diarrhoea, with three to ten stools daily. Two of the latter patients died after having developed diarrhoea, distention, and increasing prostration; and one had severe and exhausting diarrhoea, persisting throughout the disease and until put on mixed soft diet during convalescence. In June, twenty-two cases were admitted. Of these fifteen usually had enemas; one had one or two spontaneous movements; two had diarrhoea on admission, in one of whom it persisted, while in the other it rapidly subsided; and in only two did diarrhoea develop while in the house and in these it caused but three or four movements a day and subsided within three and five days, respectively.

I have stated that in the first two weeks of April, in which time there were thirty-five cases of typhoid fever in my service, there were four instances of severe hæmorrhage and three of moderate hæmorrhage; while abdominal pain, distention, nausea, and severe general prostration were common. In the three and one half months after Pasteurization had been started, there were, in ninety-two cases, three severe hæmorrhages and two mild ones; while except in three cases in which severe abdominal symptoms were apparently the chief factors in producing death soon after their admission, abdominal symptoms seemed largely to have vanished. Previous to April 15th, they had constituted the principal feature of the group of cases; after that time there was so noteworthy an absence of severe abdominal symptoms that physicians visiting the wards remarked upon it.

The darkest corner of the earlier picture is shown by the record of deaths. Among the forty-six cases admitted to the men's wards during February and March, there were three in which death was caused by exhaustion following severe diarrhoea, distention, and other abdominal symptoms that developed in the house, and as I have mentioned two similar deaths occurred in the women's ward during March. Among the ninety-two cases on the men's side after April 15th, there were no cases in which abdominal symptoms could be said to have been even important contributory causes of death. The latter statement excludes the three cases that died with abdominal symptoms soon after admission; and it also

excludes two cases that died of hæmorrhage and of perforation, respectively, as I think that these accidents were unavoidable. While I do not maintain that the three deaths especially mentioned as having occurred in the men's ward during the months of February and March, and the two in the women's ward in March were unquestionably due to bad milk, I do think that there is a large probability that they were. Dr. Despard, who was my resident from May 1st to August 1st, and who had been daily in the wards in the preceding three months, remarked at the end of the service that the character of the group of cases had been entirely changed by Pasteurizing the milk and that he believed that this measure had probably saved as many as five lives. I consider this a fair statement.

I have remarked that the one fatal hæmorrhage that occurred after April 15th was probably an unavoidable accident and hence had nothing to do with the food. I believe equally, on the other hand, that the unusual frequency of hæmorrhages in the first two weeks of April may, in the light of the other observations that I have recorded, be fairly considered to have been partially or entirely due to the infected milk. I am quite prepared to believe that milk infection may increase the destructiveness of typhoid ulcers and thus increase the frequency of both hæmorrhage and perforation.

It would have been of much interest to attempt to determine whether any particular micro-organism produced the symptoms that I have described; but this was impossible, because Dr. Ghiskey was then occupied with a series of special observations on another subject. The points that are of particular interest in this series of cases are, however, sufficiently clear and convincing as an example of the type of milk infection to which I especially directed attention in opening this paper. It is to be noted that the infection produced by the milk was apparently not in itself severe, and that the symptoms due to the milk alone would probably not have been serious in otherwise normal persons. They acquired seriousness in these cases merely because the patients in whom they occurred were already the subjects of grave disease. Furthermore, just the same symptoms may be produced by typhoid fever alone. All these points lend obscurity to the actual meaning of the symptoms and to their source in instances such as this and make it very easy to overlook both. The description that I have given has probably conveyed the impression of a much more clearly defined set of circumstances than those that actually existed. I might readily have overlooked the relation to the milk,

had the trouble developed gradually before me; but as it was, I went on duty when the disturbance was at its height, and I also had the support of the opinion of Dr. Miller, who had carefully observed the cases and after trying various dietetic measures, had concluded that it was probably due to the milk. My description is necessarily *ex post facto* and based upon accumulated records; the impression produced while the events were in progress was much less clear. I insist somewhat upon this point because it is important to realize that in the class of cases that I am discussing we do not meet with anything that is as definite as is an outbreak of diphtheria or of tyrotoxicon poisoning, for instance; the circumstances, indeed, are far less clearly defined than they are in even the cases of gastroenteritis or of sore throat and the like, that have repeatedly been traced to milk, for the primary disease renders them obscure.

That such mild forms of milk infection occur with some frequency is, as I have said, firmly believed by those that are interested in securing a sanitary milk supply. One meets not infrequently, with individual cases or with groups of cases that are in their essential features not unlike those that I have described, but the circumstances are such, as a rule, that they do not permit of a determination whether the milk is at fault or not. I have recently seen in another hospital a case that showed the following main features: A robust young man, 28 years old, ran a mild course of typhoid fever until the beginning of the third week. Up to this time he had moderate constipation, extremely little distention, and no noteworthy abdominal or other symptoms. At that time he suddenly developed diarrhœa with foul stools, distention, increased fever, and prostration. These symptoms continued, the distention grew persistently worse, he rapidly lost strength, his heart failed, and he died four days after the sudden change in the symptoms. I had seen him throughout his illness, and previous to this transformation his case had aroused no anxiety. I had not been in a position to have his milk Pasteurized or to see that he got a reliable milk, but bacterial counts were made at the time of the milk that had been given him and they ran (in cold weather) anywhere between 60,000 and 7,000,000. I cannot state that this man died of milk infection, but considering the sudden and otherwise unexplained appearance of the abdominal symptoms, and the evident ready opportunity for dangerous infection of the milk as shown by the bacterial counts, I do not think it is straining a point to suggest that he probably did.

Cases in which it is not quite so evident that something new has been added to the old symp-

toms, but in which it is wholly possible that the milk is at fault, are sufficiently common to make this matter one of very great importance. That such milk infection, even if mild, is a serious matter when a grave disease is already present, needs no demonstration. Its importance to the surgeon, particularly when he is dealing with cases that require abdominal operations or have recently been subjected to them, is not less than that to the physician.

It is also evident that patients are not properly treated, unless this source of danger is put aside. The main question is how to avoid the danger. Some authors go so far as to recommend that milk be not used in the diet of patients with typhoid fever and other acute diseases, because it is so likely to be unclean. This is, I think, the weakest and the worst way out of the difficulty. Notwithstanding the common recent teaching concerning the use of a free diet in typhoid fever, I constantly become more firmly convinced that a diet composed almost exclusively of good milk is, and will remain, the best diet for most cases of acute infectious disease, particularly typhoid fever. I am unwilling to join in any agitation against the use of all milk, because it may be bad; and, certainly, merely to say resignedly that milk is an unclean food is to submit weakly to the common carelessness and the occasional knavishness of many in the milk traffic.

(To be concluded.)

Proposed Bill to License Undertakers.—A bill is now before the Pennsylvania State Legislature for the amendment of the act of 1895 for the licensing of undertakers in cities. The bill, which provides greater restrictions in the handling of the dead to diminish the danger from infectious and contagious diseases, is supported by the State Board of Undertakers and the Funeral Directors' Association of Philadelphia. It requires that all applicants for an undertaker's license shall have had practical experience in the business of undertaking for three years continuously with an undertaker or undertakers.

Proposed Legislation Against Spitting.—A bill has been introduced in the Pennsylvania Legislature which provides that all persons wilfully expectorating upon the footway or sidewalk of a street, alley, park, public square or place of any municipality in the State, or upon the floor of any railroad car, except smoking car, street railway car, omnibus, or other vehicle for public conveyance of passengers, or upon the floor of a theatre, railroad station, or other public meeting place, shall be liable, upon conviction, to pay the costs of prosecution, with a fine of from \$1 to \$5. Boards of health shall conspicuously post notices calling attention to the act. Corporations and individuals concerned in the various places specified shall post similar notices.

ON VARIOUS PLASTIC OPERATIONS.*

By CARL BECK, M. D.,

NEW YORK,

PROFESSOR OF SURGERY IN THE NEW YORK POSTGRADUATE MEDICAL SCHOOL AND HOSPITAL; VISITING SURGEON TO THE ST. MARK'S HOSPITAL AND THE GERMAN POLIKLINIK.

The abdominal viscera have become the great centre of surgical interest at the present day. No wonder that other fields are somewhat neglected, although they are of high importance. Among the foster children of a great scientific province may be counted the kind of plastic operations which are illustrated by the cases I will present.

The first case is that of a baker, 38 years of age, who ten weeks ago smashed his right thumb in

FIG. 1.—Gangrene of thumb, one week after injury.

a dough-kneading machine. In a hospital of this city the laudable effort was made to fasten the lacerated fragment by suture. But, as shown in Fig. 1, taken a week after the accident, total gangrene of the larger part of the thumb took place. Fig. 2, made at the same time, shows the presence of a fracture of the first phalanx of the thumb in sideward displacement. It will be noticed that the extent of the gangrene is proportional to that of the area below the fracture line.

Under these circumstances the only procedure in question was amputation. Following the general practice, I would have removed not only the gangrenous portion of the thumb, but also the small fragment which articulates with the metacarpal bone, in order to save a sufficient amount of skin to protect the stump. But this would have completely destroyed the function of the

* Cases presented to the German Medical Society of New York, November 7, 1904.

FIG. 2.—Skiagraph of gangrenous thumb, showing lateral displacement in fracture of first phalanx.

thumb, and the patient might have been compelled to give up his occupation. I determined, therefore, to save the fragment and to borrow the protecting flap from somewhere else.

Encouraged by previous efforts of the same nature, I first thought of utilizing the skin of the anterior thoracic wall, but in view of the success of von Eiselsberg, as well as of von Mikulicz, I preferred to try the transplantation of a toe phalanx. I explained to the patient that he

FIG. 3.—Thumb covered by the flap, and thoracic incision line.

might gain a new phalanx, and what was more, a nail, while he would run the risk that the whole procedure might turn out a failure.

Two months ago, at the Postgraduate Hospital, I made the experiment. It was not very difficult to attach the thumb fragment to the second phalanx of the toe of the same side and to immobilize arm and leg by a well padded plaster of Paris dressing. For still greater security, I fastened the ball of the thumb to the dorsum pedis and connected the region of the elbow with that of the knee, by stout silk. In spite of these precautions too much tension was exerted on

the stump; the patient was rather nervous, and nutrition was inhibited. Failure convinced me that a secure apposition cannot be guaranteed by suturing the soft tissues only, but only by

FIG. 4.—Hand shifted under the thoracic skin-flap after removal of stitches (ninth day).

connecting the adjoining bones with a silver wire suture.

I then returned to my first proposition, lifting a fold of skin together with a few fibres of the pectoralis major muscle. To get muscular tissue easily, the anterior axillary line just below the mamilla is to be preferred as best for that

FIG. 5.—Flap healed, six weeks after separation.

FIG. 6.—Defect in frontal bone, showing diameter of skull in semilateral exposure.

purpose (see Fig. 3). The direction of the semilunar incision should be transverse, and as some shrinking of the flap is to be anticipated, it should be liberally outlined. The width of the pedicle of the flap amounted to less than an inch. About three fourths of the circumference of the thumb

FIG. 8.—Osteoperiosteal flap filling the frontal and lateral flaps covering the skull gap.

could be protected by the flap. A relaxation suture was carried between the ball of the thumb and the sternal region, and the whole arm immobilized by a thoracic plaster of Paris dressing. A fenestra was left in the region of the wound in order to control its course.

FIG. 7.—Defect of forehead healed by granulation.

FIG. 9.—Final result of osteoplastic operation.

After nine days I removed the thoracic flap, united the tissues, and sutured the cut surface of the flap to the gap in the stump.

As can be seen, the stump is now amply covered. There is enough projecting material left

FIG. 10.—Defect in forehead filled up with osseous tissue, nine months after transplantation.

FIG. 11.—Four fingers grown together in a shapeless mass.

to permit grasping with this stump (Fig. 3). The defect left at the toe could be partially covered with skin taken from the dorsum of the foot, and has not disturbed the patient.

FIG. 12.—Skiagraph of Fig. 11.

Regarding the fact that the thumb possesses a value equal to the remaining four fingers, it seems to me to be of the greatest importance that the possibility of saving even so small a portion should be thoroughly considered before operation.

The second case is analogous to the first. A laborer, 40 years of age, had sustained severe burns, all of the third degree, in a fire. The wounds of his forehead healed without difficulty, but the dorsum of the left hand became extensively necrotic, and a large defect remained, for which Dr. I. M. Rottenberg, who treated the patient at the time, recommended transplantation of skin.

Four months ago I followed this proposition by forming a large flap in the anterior thoracic wall, so as first to make two longitudinal incisions, and after undermining the outlined area,

FIG. 13.—Denuded fingers shifted under the thoracic flap.

to give protection to the necrotic area of the hand. The hand, as indicated in Fig. 4, was shifted below the undermined flap and fastened to the margins of the denuded area of the hand. A large piece of xeroform gauze was placed be-

who gave a history of infection. Originally she came to my clinic at the Postgraduate Hospital to be treated for enormous necrosis of her frontal bone. I removed the os frontis in its totality, as can be seen by the bone fragments I present here, and tried to heal up the large defect by the open antiseptic wound treatment, keeping the absorbent gauze saturated with a strong solution of bichloride of mercury. At the same time constitutional treatment was administered.

Although the bone was removed in its entirety, as can be seen from the skiagraph (Fig. 6), which by slight lateral exposure shows the diameter of the bone at this area, no brain symptoms were ever observed during treatment. The extent of the lesion is shown in Fig. 7. Nine months ago I covered the lacuna by taking an osteoperiosteal flap from the top of the skull and implanting it into the defective surface by turning it forward. The large defect produced on the top of the skull was covered by extending the incisions sideways and downwards, thus forming two lateral flaps, which were drawn together in the middle of the

FIG. 14.—Index and small fingers covered by thoracic skin at the dorsum of the hand, four weeks after division.

FIG. 15.—Appearance of palm four weeks after separation of thoracic flap

low the palma manus in order to protect the exposed thoracic wound portion. The region of the wrist, as well as that of the elbow, was secured by strong relaxation sutures. Arm and thorax were surrounded with a plaster of Paris dressing, leaving a fenestra open for the treatment of the wounds. After a week I severed the upper integumental bridge and after another five days the lower. Fig. 5 shows the flap six weeks after the separation of the lower flap portion. The cosmetic, as well as the functional result may be called good.

The dorsum of the right hand shows considerable cicatrization, so that I am still undecided

FIG. 17.—Result three weeks after additional transplantation from thigh.

FIG. 16.—Fenestrated plaster of Paris dressing for transplantation from the anterior aspect of thigh.

whether epidermization will not be indicated. The larger thoracic wound is perfectly healed and causes no disturbance. Without transplantation the hand would, I dare say, have become contracted, which would have caused complete functional disability.

The third case is that of a woman, 38 years old,

denuded area. In front of the flaps, as well as behind, a small gap remained which could not be protected by scalp tissue; it filled up by the granulation process (Fig. 8). The small cicatricial area remaining is now fully covered by the hair. The frontal flap is also covered by hair, which does not worry the patient, since this arrangement corresponds with the latest fashion (Fig. 9).

Fig. 10 shows the gap nearly filled up with osseous tissue. On percussion it has been noted that the frontal defect is amply protected by new bone.

Case IV is that of a laborer, 53 years old, whose hand was caught in a printing press two years ago. It seems that his fingers were stripped of their skin, and no effort at epidermization and keeping the fingers separate being made, the four

FIG. 18.—Contraction caused by burn of the third degree.

fingers grew together in one confluent mass (Fig. 11). The skiagraph (Fig. 12), taken in July, 1904, that is two years after the accident, shows the phalanges tightly forced together. The outlines of the phalanges do not show distinctly, which is due partially to inflammatory atrophy of the bones, and also to compression and overlapping. Further up towards the wrist the bones appear to be normal.

FIG. 19.—Axillary flap transplanted from back.

This formidable stump was not only useless, but also an encumbrance to the patient. After ascertaining by the Röntgen method that the phalanges were still in existence, a fact which was by no means made evident by simple palpatory examination, I determined to separate the phalanges, even at this late period, and to try to cover them by transplanted skin. I began this task three months ago at St. Mark's Hospital; first removing the cicatricial tissue from the fingers, and then separating the little finger and the index finger. Then two longitudinal incisions were made after the methods observed in case No. 2, part of each finger being as much surrounded by the skin cover as possible (Fig.

FIG. 20.—Contraction of elbow, caused by burn, cured by transplantation of thoracic flap (at the eighth rib).

13). After nine days the upper, and after another five days, the lower portion of the flap were divided and trimmed around the small and the index fingers. Figs. 14 and 15 show the result four weeks later. Then the middle and fourth fingers were similarly treated. This time the flap was taken from the upper thoracic region, and in view of the necessity of furnishing new skin for the palmar surface, a tongue shaped flap was outlined instead of drawing on the thoracic integument. The base of the flap was at the left sternal margin and its top at the anterior axillary line. After reverting the flap the palmar surface of the two denuded fingers was sewed to the wound surface of the reverted flap, and the remaining thoracic gap almost entirely united by suture. Relaxation sutures were also used to secure good apposition. The arm and thorax were surrounded by a fenestrated plaster of Paris dressing. After nine days the pedicle of the flap was divided, and its wound margin sutured to

the palmar region below the upper ends of the middle and fore fingers. After another week the two fingers were separated, and as an abundance of skin was still left I was able to surround a portion of each finger with skin, thus furnishing a barrier to the tendency to an undesirable union.

The patient is now able to move his fingers well, and while their appearance does not satisfy aesthetic standards, he at least has fingers, and is able to use them. I would suggest that in cases of such injuries transplantation should be tried shortly after the injury is sustained; if possible as soon as the first reaction is over.

OSTEOARTHRITIS OF THE SPINE; REPORT OF A CASE.

By H. F. STOLL, M. D.,

HARTFORD, CONN.

This case is reported as it demonstrates the rather common mistake made, in considering the leg pains of spinal osteoarthritis to be sciatica. That diagnostic error would scarcely be made if patients were subjected to complete physical examinations before an opinion was given. It also shows the great amelioration of the symptoms following spinal fixation.

Charles F., aged 38 years, married, a baker by occupation and a native of Germany, was admitted March 5, 1904, to the surgical side of the Hartford Hospital under the service of Dr. Bunce, the writer being house surgeon at the time. Family history, negative. Past history: Many years ago he received a bullet wound of the abdomen from which he made a good recovery; four or five years ago he had "muscular rheumatism" in his left thigh, which lasted only a few days. Otherwise he has always been well until his present illness. He drinks several glasses of beer a day, and occasionally to excess. He has had gonorrhoea, but not syphilis.

Present illness: In May, 1903, ten months before admission, he first noticed a "heavy feeling" in the small of his back. About six weeks later he began to have cramps in the back of the right thigh and leg. Soon similar pains were experienced in the left leg. His business necessitated working nights and the pains were always more severe when he first arose in the afternoon. At first they would wear off as he "got limbered up," but in about three months they became nearly constant, shooting down the right leg at one time and down the left one at another.

Since November 1st, the pain has been wholly in the right side; about this time he first noticed a "swelling" of the right hip. He has not been able to work for seven months as the pain is now so severe that he cannot walk a block without stopping to sit down once or twice on the curb. Many physicians were consulted and with one exception the diagnosis was sciatica. The last one told him he had a "tumor of his hip," and he comes to the hospital for x ray treatment.

Physical Examination.—The patient, a well nourished man, walked into the hospital limping with the right leg. As he stands the body is inclined forward and towards the left, the weight being borne by the left leg. The right one is held slightly in advance of its fellow with the foot abducted. The plantar arches are normal. The right hip is so held that there appears to be considerable fullness extending from the crest of the ileum to the right trochanter major. The gluteal folds are equal. There is a double scoliosis, the smaller one with its concavity to the right being in the upper dorsal region, and the large one in the lower dorsal and lumbar regions. Flexion of the vertebral column is much limited (see figure), especially in the lower half

Normal spine.

Osteoarthritis of the spine.

"Poker Back."

of the dorsal and lumbar regions. Flexion to the left is normal, but much limited to the right. Extension is also somewhat limited. When in dorsal decubitus the position of ease is with the right leg flexed on the thigh, and the thigh on the pelvis, the whole extremity being rotated outward. There is no shortening of the legs and no atrophy. There is no limitation of movement at the hip joint, nor is there any tenderness over the sciatic nerve. The prominence observed over the right hip when erect is not present in ventral decubitus. The knee jerks are equal and exaggerated. There is no ankle clonus. The heart, lungs, and abdomen are negative.

A plaster jacket was applied and he was discharged with instructions to return for a new cast in a month.

April 19, 1904. The patient returned for a new cast. Since leaving the hospital there has been constant improvement, the pain having largely disappeared, being present now for a short time in the back and legs when he first gets up. Recently a five mile walk was followed by no unpleasant effects. He now walks without limping. He was given a new cast and discharged.

July 13th. He returned for a plaster jacket, having broken the one applied in April. Since his last admission he has worked steadily on the street railroad and been free from pain while the cast was intact. He stands squarely on both feet and does not limp. There is no scoliosis. He was discharged after being fitted with a plaster jacket.

October 17th. The patient was readmitted.

He has worn his jacket constantly until three and a half weeks previously, and has been free from pain. For three days after he removed the jacket he felt as usual, but unfortunately at that time he lifted a heavy weight, and since has had pain in his back and left leg that has been increasing in severity ever since. The cramps in the left thigh are preceded by a burning sensation in the outer aspect of the left leg.

The mobility of the spinal column does not seem to be materially increased since the first examination made seven months before. The accompanying photograph was taken during his last admittance. It shows the extreme limit of flexion and should be compared with the normal spine in the same picture.

A new cast was fitted and in a few hours he remarked that he "felt as well as ever."

Through the courtesy of Dr. Philip Bunce the writer was permitted to report this case.

417 ALBANY AVENUE.

GONOCOCCUS INFECTIONS IN CHILDREN, WITH ESPECIAL REFERENCE TO THEIR PREVALENCE IN INSTITUTIONS AND MEANS OF PREVENTION.

By L. EMMETT HOLT, M. D.,

NEW YORK,

PROFESSOR OF DISEASES OF CHILDREN, COLLEGE OF PHYSICIANS AND SURGEONS (COLUMBIA UNIVERSITY).

(Concluded from page 527.)

MEANS BY WHICH THIS FORM OF INFECTION IS SPREAD.

These will of course differ somewhat with the age of the children. Our patients have been mostly infants and children under three years, nearly or quite all wearing napkins. At this age direct contact, sexual or through the hands, plays no part.

The first and most obvious means of infection is through the medium of napkins. I have no doubt that gonococcus vaginitis is more frequently spread among young children in this way than in any other, especially in such institutions as day nurseries and homes for foundlings. Thorough disinfection of napkins is seldom followed in such places. For several seasons almost our entire efforts to arrest the spread of the disease were directed toward the handling of napkins. These were soaked in disinfectants, boiled in suds, and put through a steam sterilizer. At one time we even went so far as to abolish ordinary napkins and to use only gauze and cotton pads, which were burned as soon as soiled. Yet in spite of all these measures the infection spread unchecked. Thermometers were suspected and a separate one for each child employed, kept in 50 per cent. alco-

hol when not in use. Bottles and nipples were kept separate with the greatest care. Sponges were early abolished; wash cloths likewise were dispensed with, and only pieces of gauze or absorbent cotton used for bathing, which were immediately destroyed. Bathing in tubs was interdicted, yet, notwithstanding, case after case developed so long as children remained in the ward with those who were infected. These children came into no direct contact with one another, and even autoinfections, such as ophthalmia from vaginitis, were exceedingly rare. There could be but one explanation, viz., that infection was carried by the nurses in the process of bathing and feeding, but particularly in the changing of napkins. When it is realized that this is a thing which must be done from twelve to fifteen times every day the possibilities will readily be appreciated. Not only was it found impossible to keep infected children in the wards with others, but they could not be cared for by the same nurses. Quarantine of both children and attendants was therefore demonstrated to be the only means by which spreading could be checked.

What seems to be conclusive proof that the disease can be carried by nurses has twice been seen in the hospital. On the fourth floor was a ward containing cases of gonococcus vaginitis; on the seventh floor a child in quarantine for suspected diphtheria. Owing to a shortage of night nurses it became necessary for the same nurse to change napkins in the ward containing the cases of gonococcus vaginitis and of the child in quarantine three floors above. This child developed gonococcus vaginitis and no other communication than through the night nurse could be traced. There was no gonococcus vaginitis on the fifth and sixth floors, the day nurses were separate, different thermometers were used, and the napkins did not go to the same laundry. It seemed therefore conclusive that the nurse had conveyed the disease. The same thing occurred again a few months later under circumstances precisely similar. The night nurse now wears rubber gloves if she has to change napkins of gonococcus cases and others at the same time.

One of the most interesting as well as the most difficult questions to solve has been the portal of entry of the organism in the cases of gonococcus arthritis. It will be recalled that of these 26 patients 19 were males, and that only one of these had ophthalmia. In none was a urethral discharge observed. Many cultures were made from urethra, eyes, nose, mouth of these children—all with negative results. The time after admission when the symptoms of gonococcus arthritis were

first noticed is worth recording. In 5 cases they appeared during the first week after admission and in 11 cases during the second week; the others varied from the fourth to the eleventh week.

I do not think we can state definitely just how these children were infected, but I have a strong conviction that it was through the mouth. Most of these patients were very young infants, many suffered from marasmus and also from thrush. In one fatal case an abscess in the tracheal wall was found, the pus from which contained the gonococcus. The method of cleansing the mouth formerly employed in the hospital was that now in vogue in many institutions, and consists in the use of the nurse's little finger upon which is wound absorbent cotton. From the facts cited above I strongly suspect that this was the mode of infection, though we were never able to recover the gonococcus from the mouth by culture. This use of the nurse's finger has now been abolished and a small swab made with a wooden toothpick and absorbent cotton substituted, a method in every way to be preferred.

The possibility that either nurses or servants might be the origin of the house infection in children, was constantly in our minds. Yet, although the closest watchfulness was constantly maintained no evidence whatever could be found to support this opinion. Routine microscopical examination of vaginal discharges in nurses were not made; but this was done in several cases where some suspicions attached to wet nurses or servants, but always with negative results. I do not think that this could have been the source of infection in our institution. In every ward epidemic of gonococcus vaginitis we were able to trace the infection to one or more children admitted with the disease.

It is also worthy of record that during the entire eleven years we could find no evidence that any nurse or servant contracted gonococcus vaginitis from the children; the only case of infection among nurses being one of ophthalmia already mentioned.

PROPHYLACTIC MEASURES.

In a disease so difficult to cure and so highly contagious the utmost importance must be attached to measures of prevention. In the light of our experience two things are essential in institution practice: First, cases of gonococcus vaginitis must so far as possible be excluded. In the second place, if admitted by accident or otherwise they must be quarantined. In excluding cases only one thing can be depended upon, viz., microscopical examination of a smear from the vaginal secretion before the child is received.

This rule has been followed in the Babies' Hospital now for nearly a year with the effect of practically ending our difficulties. Certain cases can no doubt be recognized without a microscopical examination, but there are many others in which this is not possible. Mothers or others desiring admission of children frequently bathe them carefully before applying, especially if they have been refused admission elsewhere because of the discharge, and at the time of the application none may be noticed. Again, the milder forms cannot be detected by a gross examination. We must regard as dangerous not only cases with much pus and the gonococcus present, but also those with little pus and the gonococcus, and as very suspicious and requiring the closest kind of observation, cases with a moderate number of pus cells, even though no specific organisms are found. Of course at a general hospital children often apply with conditions, such as pneumonia and appendicitis, where they must be received, even though suffering from vaginitis. In special hospitals for diphtheria or scarlet fever also they must be received. For such children isolation wards should be provided. They should never be placed in the general ward with other children, the danger to boys being of course very much less than to girls.

Cases to be excluded from general wards should be not only those of vaginitis, but of ophthalmia and acute gonococcus arthritis as well; the latter may at first thought possibly seem quite unnecessary. No infection is possible from the joints themselves unless they have been opened. But such cases no doubt acquire the disease through some mucous surface, and if so acquired it may spread from the same one. In fact, we have one instance in which a boy with gonococcus arthritis of the elbow and with no lesion of the mucous membrane discoverable was apparently the source of infection for others in the ward. At present, therefore, and until the exact mode of entry of the gonococcus in these cases is positively known, I believe it is safer to isolate them.

Even with the rigid entrance conditions imposed, we have found that occasionally a case escapes detection. In order that such may be discovered and any spreading of the infection prevented, we have adopted the rule of examining microscopically once a week a smear from the vaginal discharge of every girl in the house. In a hospital where the admissions amount to from 50 to 100 children each month such frequent examinations seem to be necessary; they are certainly an added safeguard. In institutions which serve as homes for young children, where the ad-

missions are fewer, less frequent general examinations may suffice, but they are very desirable. In institutions where microscopical examinations are not possible, the use of the labial fold of gauze mentioned previously will be found valuable to detect slight discharges in infants; if these are purulent the case should be regarded as specific unless shown by microscopical examination to be otherwise.

If children are isolated, the quarantine must extend to their nurses and attendants. Not only should the day nurses, but the night nurses, be separate. The latter are I believe a not infrequent cause of spreading infection of all kinds in hospitals. On no account should napkins, underclothing, or sheets from infected children go into the general laundry of the institution.

The duration of quarantine it is difficult to fix accurately. It is not enough to continue it until all inflammation has subsided and a single negative examination for the specific organisms has been made; such children must be closely watched for two or three weeks longer and even then we may err.

In addition to the methods already considered, prophylaxis should include the most scrupulous care with reference to the napkins and clothing, especially the underclothing, of infected children. Napkins should be worn by all children with gonococcus vaginitis, no matter of what age, in order to prevent infection of the hands and thus a transference of the organism to the eyes or other parts. After their removal, napkins should be thrown into a strong disinfectant solution—we are now using formacol from 2 to 5 per cent.—and should invariably be washed separately from those of the rest of the institution. At present it is our custom to boil the napkins in hot suds, after which they are put through a steam sterilizer. The underclothing and sheets from the beds of infected children should be treated in the same way. In the case of young children special care is to be taken with reference to the toilet. Sponges are an abomination and should never be used in bathing in institutions. Wash cloths also may be a means of conveying infection and should not be employed about the buttocks or genitals, but only muslin, gauze or absorbent cotton, which can be destroyed after once using.

Infection, no doubt, in many cases is spread by the bath water where more than one child uses the same bath, as is not uncommon in many institutions. Even the bath tub may harbor the infection and convey the disease, although the water has been changed. During an epidemic

tub baths should be forbidden. A separate towel for each child is absolutely essential, and since towels easily become mixed these should be frequently sterilized like the napkins.

The most scrupulous precautions should be taken with reference to the nurse's hands; not only on account of the danger to herself but also lest she may by the hands spread the disease in cleansing the mouth or in handling the nipples of the feeding bottles. Nurses' hands should be carefully washed in a disinfectant solution after bathing or changing the napkins of each child.

Thermometers, catheters, syringes, or tongue depressors used for infected children may be a medium of contagion unless boiled or otherwise sterilized after use. It is hardly necessary to add that the system of feeding should be such that there is no possibility of the same nipple being used by different children.

After an outbreak in a ward, general fumigation and disinfection should be employed with as much thoroughness as after an outbreak of diphtheria or scarlet fever. Not only woodwork, beds, and bedding should be washed, but bath tubs, basins, and everything else which comes in contact with the child. The above measures if thoroughly carried out will do much to minimize the danger of ward infection. But we frequently saw all these things thoroughly done and yet the disease spread from one child to another until isolation was practised.

The scope of this paper does not permit me to enter fully into methods of treatment; none has been found by us to be altogether satisfactory.

GENERAL CONCLUSION.

1. We must recognize gonococcus vaginitis as a very frequent disease and one to be constantly reckoned with in institutions for children. It is also very frequent in dispensary and tenement practice and not uncommon in private practice of the better sort.

2. In its milder forms and in sporadic cases it is extremely annoying because so intractable; in its severe form it may be dangerous to life through setting up an acute gonococcus pyæmia or infection of the serous membranes, and in its epidemic form it is a veritable scourge in an institution.

3. The highly contagious character of gonococcus vaginitis makes it imperative that children suffering from it should not remain in the same wards or dormitories with other children. A similar danger though less in degree exists with the gonococcus ophthalmia and acute gonococcus arthritis or pyæmia.

4. It is practically impossible to prevent the

spreading of the disease if infected children remain in the wards with others. They must either be excluded from the hospital or if admitted immediately quarantined.

5. Cases of gonococcus vaginitis can only be excluded from hospital wards by the systematic microscopic examination of smears from the vaginal secretion of every child admitted. If a purulent vaginal discharge is present, such examinations are imperative and should be made as much a matter of hospital routine as the taking of throat cultures in children with tonsillar exudates. In the absence of microscopical examinations a purulent discharge in a young child may be assumed to be due to the gonococcus.

6. The quarantine to be effective must extend to nurses and attendants as well as to children. Furthermore, the napkins, bedding, and other clothing of infected children must be washed separately from that of the rest of the house.

7. Where the gonococcus is found with no vaginal discharge or with a very slight discharge, children should also be quarantined, although it is impossible at present to say to what degree such cases may be dangerous in a ward. One of the greatest difficulties in connection with the gonococcus vaginitis arises from the prolonged quarantine rendered necessary from the fact that these cases are of very chronic character and very resistant to treatment.

8. The danger to nurses from accidental infection, especially in the eyes, is considerable. At the present time they are not sufficiently instructed in this respect.

14 WEST FIFTY-FIFTH STREET.

DISCUSSION.

DR. F. C. WOOD said that some of the methods of the clinical pathologist might be of interest. The practitioner must always depend upon the morphological identification of the organism in smears. He had been accustomed to take advantage of the sharp morphology of the organisms when stained by means of the Jenner blood stain. Smears should be thinly spread and as soon as dry could be stained in the alcoholic mixture for three minutes. The Jenner stain gave a good differentiation because the cell body stained reddish, while the gonococcus took a deep blue stain. There were other cocci which could assume the biscuit shape and were also found in the bodies of the leucocytes. It was advisable to keep some stained smears containing undoubted gonococci to control the microscopical findings. If after some search organisms were found which were in the pus cells but which did not correspond to the morphology of the gonococcus it was convenient to do a Gram stain on top of the Jenner. The slide should be ringed with some waterproof ink or the position of the doubtful cells marked on the coordinates of a mechanical stage, and bet-

ter after a fixation of the slide by heat; a Gram stain could then be carried out as usual. Special care should be taken in obtaining the material so that the difficulties of diagnosis were not increased by the presence of a large number of saprophytic bacteria which were frequently present in the vulvar region. It was better to pass a small platinum loop into the vagina and urethra if possible, as the material would thus be uncontaminated. For preliminary disinfection of linen he recommended formaldehyde or carbolic acid, after which the clothing should be boiled or thoroughly steamed. The gonococcus is easily destroyed, though a non-penetrating disinfectant such as bichloride might leave living organisms inside a mass of mucus or pus.

DR. J. CLIFTON EDGAR said that from the obstetrician's standpoint gonococcus infection in infants concerned the eyes, mouth, stump of the umbilical cord, and the vulvovaginal canal. These are all infections of the mucous membranes excepting the umbilicus, which is an infection directly into the lymphatics or veins of the stump of the umbilical cord. In the experience of the obstetrician gonococcus infection of the eyes is the form of this infection most frequently met with. The delicate mucous membranes of the eye offer little resistance to this infection, and then injury during vaginal examinations or during labor may give rise to abrasions of the mucous membranes which render the occurrence of infection more liable to supervene. He said that we knew very little in regard to gonococcus infections of the mouth, umbilical stump, and vagina in the newly born and that nothing of value had ever been published on these infections. This was probably because the subject was divided between obstetricians, pædiatrists, and ophthalmists, each specialist caring only for a particular aspect of the subject. Recent writers made scarcely any distinction between gonorrhœa neonatorum and the same disease in young infants in general. It had been asserted that vulvovaginal gonococcus infection of the newly born had been recorded only a few times. Dr. Edgar believed that gonococcus infection intrapartum or directly postpartum of the mouth, umbilical stump, and vulva and vagina were very rare conditions. The obstetrician was chiefly interested in the prophylactic treatment of gonococcus infection of the newly born. The vaginal secretions have no bactericidal action on the gonococcus. Where this infection exists the fetus might be infected in utero and be born with a well developed conjunctivitis. If the vagina was usually sterile it needed no preparation for labor, if conditions were otherwise it did. He believed that in hospital practice such preparation was necessary in order to prevent ophthalmia neonatorum. In private practice he was not accustomed to use antepartum vaginal irrigations in deference to the popular belief that there was less gonococcus infection in private practice, yet occasionally he had seen gonorrhœal ophthalmia in spite of Credé's nitrate of silver method of prevention. Antepartum vaginal preparation, and Credé's nitrate of silver method after birth would greatly reduce the percentage of gonorrhœal ophthalmia, but they could

not abolish it. The obstetrician knew of no method that would positively prevent the occurrence of gonococcus infection of the fetus in a woman the subject of such infection. This danger would constantly threaten the child so long as men with gonorrheal infection are permitted to marry and women with this infection to conceive.

DR. R. B. KIMBALL said that he wished to emphasize the point that the only way to rid an institution of this infection was to prevent the entrance of more cases. They should be kept out of the wards. He related the history of an infection which broke out at Seabright in which the cases were carefully isolated and every possible precaution taken to prevent the spread of the disease, yet in spite of all their care the infection spread. He attributed it to the fault of the night nurses.

DR. HENRY KOPLIK said that when he took charge of the Mount Sinai Hospital service for children there was not a female child in the service who was not the subject of this infection. When a child was once infected he thought that child was more or less crippled for life. In his efforts to eliminate the disease he had finally devised a system of prophylaxis and isolation which was very satisfactory. Diapers were destroyed after being soiled. This was expensive, and in visiting other institutions to ascertain what cheaper method could be used he discovered a state of affairs confirmatory of what Dr. Holt had stated. There seemed to be no institution devoted to the care of children in which gonococcus infection was not endemic and epidemic. Dr. Koplik advised that children be bathed in their cribs as one means of preventing the spread of this disease. During the past two and one-half years Dr. Koplik had not had an epidemic of this infection, which he attributed to his prophylactic measures. Every case of gonococcus infection was immediately isolated, given a separate nurse, separate bed, and separate utensils. The beds were marked with red ribbons. Every child had its own thermometer, bed pan, liquid soap, etc. He did not believe that diapers, etc., could be disinfected, chiefly because nurses and help could not be depended upon to carry out instructions.

DR. T. S. SOUTHWORTH thought that it was more difficult to stamp out gonococcus vaginitis than diphtheria, scarlet fever, etc., because the former was clinically and apparently cured and might still be a menace, since the disease might be latent and break out at any time. He confirmed what Dr. Holt and the others had said in regard to the prevalence of this infection in the institutions of the city. Isolation he thought the only way to cope with the trouble, as ordinary nurses were not competent to prevent the extension of the disease from one patient to another. The efficiency of treatment depended upon the thoroughness with which it was carried out. Irrigations of bichloride solution, nitrate of silver, etc., were efficient if properly given. He advised the introduction of a gauze wick soaked in a five to ten per cent. solution of ichthyol, or a four to ten per cent. solution of silver. This prevented the walls of the vagina from coming into appo-

sition, facilitated drainage, kept up continuous medication, and emphasized the surgical nature of the case and the necessity of keeping on a diaper.

DR. ARNOLD KNAPP spoke of the diagnosis of gonococcus infection of the conjunctiva in the newly born, which he said could not always be made early from the clinical picture. There were very severe forms of conjunctivitis due to pneumococcus or streptococcus and quite mild forms due to the gonococcus. A microscopical examination should be resorted to in making a diagnosis. The prophylactic treatment was of the greatest importance. He thought Credé's method was very severe. He advocated disinfection of the parturient canal, careful cleansing of the eyelids after birth as the most important prophylactic measures. In gonococcus infection of the eyes he recommended ice compresses, frequent irrigation of the conjunctival sac and later silver nitrate.

DR. J. E. WEEKS said that the infection of the conjunctiva in children was the most frequent condition met with by the ophthalmologist, although it was not so frequent between the ages of three and ten years as under three. He believed that there was not an institution in New York city that was devoted to the care of infants and young children, but had had an epidemic of gonococcus infection at some time or other.

DR. W. R. TOWNSEND said that from the orthopaedist's standpoint there were three classes of cases, peri-arthritis, simple effusions into the joints, and cases of mixed infection with the gonococcus present. Plaster casts or braces he believed to be always indicated to get complete immobilization of the involved joints. Extensive operations upon the bone, even when involved, were not advised. The prognosis in arthritis occurring in children was better than in adults, because sepsis was better tolerated and recuperative powers were better.

DR. A. JACONI advised that records of gonorrheal infections should be obtained for two or three years at least from the different hospitals and dispensaries, which would give ample material to present to the board of health, and then, but not till then, could the Academy of Medicine expect it to take official notice of it. He did not think any motion should be made at present having for its purpose the presenting of the matter to the board of health.

DR. PRINCE A. MORROW believed that it would be useless to present the matter to the health board, because the board knew of the existence of the evil and regarded it as a *noli me tangere*.

Meeting of the Boston Medical Library.—A meeting was held on March 22nd at the library, and the following papers were presented: A Study of the Objective Methods of Diagnosis of the Stomach in a Medico-surgical Clinic, with Reports of Cases, by Dr. H. F. Hewes; The Recent Surgical Conceptions of Non-Malignant Disease, by Dr. J. G. Mumford. Discussion by Dr. F. Pfaff, Dr. J. C. Munro, Dr. F. B. Lund, Dr. E. P. Joslin, and Dr. C. L. Scudder.

A BRIEF RESUME ON THE ACTION OF SOME OF THE IMPORTANT SOMNI- FACIENTS, WITH CLINICAL NOTES ON A NEW HYP- NOTIC.

By A. P. STONER, M. D.,

DES MOINES, IA.,

PROFESSOR OF PRACTICAL THERAPEUTICS, MEDICAL DEPART-
MENT; PROFESSOR OF PHYSIOLOGY AND ORAL SURGERY,
DENTAL DEPARTMENT, DRAKE UNIVERSITY.

While I do not pretend to champion anything but the clearly defined and legitimate use of hypnotics, I do contend that at times they become as essential in the treatment of the overworked and partially exhausted nerve cells as the rest treatment itself in neurasthenic states, or the splint in certain traumatic injuries. In my own practice I have yet for the first time to regret the careful use of the sleep producers in any case, acute or chronic, when insomnia was a marked feature.

Chloral still holds its place as one of the purest and most effective hypnotics. Its depressing action upon the centres in the cord and medulla, however, is so marked as to preclude its use in some cases of pulmonary and cardiac affections. My clinical experience leads me to believe that it indirectly affects the heart and circulation by diminishing the blood pressure, but numerous experiments prove that it is a direct heart poison. Sudden death has followed its use from paralysis of the heart muscle. Death has also resulted from sudden paralysis of the respiratory centres.

Sulphonal and trional are less dangerous, and in most instances just as effective. The former is slow in action, and in my hands has never proved as satisfactory as the latter. Acute poisoning is less apt to occur from either of these drugs than from chloral. Therefore, as a rule, I have preferred to use them in all cases in which the circulation or respiration was strained or weakened.

Recently a new hypnotic has been brought to my notice, and my experience with it thus far seems to justify the conclusion that it is the peer of chloral in activity, without any of the latter's depressing phenomena upon the respiratory or circulatory functions. It is chemically trichloroisopropylalcohol

and is known as isopral. It occurs as a colorless, shining, crystalline powder, slightly soluble in water, and has a burning taste and a characteristic, pungent odor.

My experience with the drug has extended over a period of one year, and includes only cases in private practice. I herewith append brief notes on some of the cases in which it has been used, all of which I have carefully observed. Cases which I have not been able to follow closely are not included.

CASE I.—Mrs. D. P., housewife, suffering from hysterical excitement and sleeplessness due to the death of her brother; had a neurasthenic history with much agitation. Isopral, one gramme, produced sleep in one hour; excitement was allayed within one half hour. She slept six hours without awaking.

CASE II.—Belle R., domestic, had simple neurasthenia and had not slept for two nights. Isopral 0.65 grammes was ordered at bedtime. Not wishing to take medicine to procure sleep, the patient avoided taking the capsule until a late hour. The action was prompt, and the sleep lasted seven hours, although somewhat disturbed by dreams. About two weeks later the same amount was taken upon an empty stomach, and produced a slight burning sensation in the epigastrium. The sleep which followed was somewhat disturbed. On the following day a dose of one gramme at bedtime procured a good night's rest, the patient feeling refreshed upon awaking.

CASE III.—Walter B., solicitor, had suffered from sexual neurasthenia, and had not slept for three nights. Isopral, one gramme, at bedtime produced a sleep of five hours. On the following night one gramme was given; there were periods of waking and seminal emissions; much weakness (not due to the drug) was manifested on the next morning. On the following night 0.65 gramme gave the patient a restful sleep of about eight hours' duration, without dreams.

CASE IV.—Mrs. L., afflicted with ovarian neuralgia, neurasthenia, and hysteria. Her insomnia was completely overcome by 0.65 gramme of isopral, taken three hours after dinner. Sleep was normal and left no untoward effect.

CASE V.—Mrs. B., housewife, had acute endocarditis, and was unable to sleep during convalescence. Isopral was administered in a 0.65 gramme dose. The patient expressed herself as having had a "beautiful" sleep from its effect. No perceptible deleterious action upon the heart followed its use; slight distress was felt in the stomach, however.

CASE VI.—M. S., suffered from chronic morphinism and had undergone appendectomy. Following the withdrawal of the opiate there was no sleep for four nights. Isopral, 0.65 gramme, produced refreshing sleep. The drug in like doses was repeated upon several subsequent occasions, always with most gratifying results. It was always given upon an empty stomach, and sleep was generally produced within one hour.

CASE VII.—Miss K. B., waitress, had acute salpingitis. During convalescence she was unable

to sleep. A dose of 0.65 gramme had no effect, as it was taken immediately after eating. It was not repeated until the pains became less severe, when 0.45 gramme produced partial rest. The following night 0.65 gramme was followed by good results.

CASE VIII.—M. J. C., railway conductor, had herpes zoster, and had had no sleep for several nights. He took isopral, 0.75 gramme, at 9 p. m., but did not retire until after 10 o'clock. Not being asleep at 11 p. m., the dose was repeated; thus he took one and one half grammes. The sleep resulting therefrom was prolonged until 9 o'clock the next day. This was the largest dose I have given, yet there were no untoward effects following its use. On two occasions this patient took 1.35 grammes at one dose without producing any disagreeable symptoms and with satisfactory results as to its hypnotic action.

CASE IX.—J. E., merchant, suffered from an attack of nerve prostration following pneumonia. There was much general weakness coupled with almost complete insomnia, for which 0.65 gramme of isopral was given at 9 p. m., and repeated in one hour. He slept until 10 a. m. the following day. The sleep was apparently normal, and the patient felt refreshed, and no untoward effects were experienced.

CASE X.—Mrs. L. B., saleswoman, suffered from cystic ovaries and neurasthenia. Following an exacerbation of pelvic inflammation she was unable to sleep. There was mitral insufficiency with marked arrhythmia of the heart's action. Isopral, 0.65 gramme, was given and resulted in a delightful sleep without any apparent depression of the circulation.

CASE XI.—Mrs. John P., housewife, had tuberculosis pulmonalis, giving a history of not having slept for a week. Both lungs were involved; the evening temperature was 103.4°, and the pulse ranged between 95 and 118. Isopral, 0.65 gramme, was given upon an empty stomach at 9 p. m., and she slept until 8 a. m. the following day. A dose of one gramme was administered on the following night, for the purpose of observing its action on the respiration and pulse. The respiration, which had been noted as ranging between 23 and 27, was not affected. Neither were there any perceptible changes in the heart or circulation.

In all cases I have carefully studied the clinical effects upon the circulation and respiration. Thus far, however, in no instance have I been able to note any signs of depression in either. It does not slow the heart beat as does chloral, and I believe it to be equally effective in its action as a hypnotic. It is best given in capsules or wafers. When I first began to use the remedy the dose was not well established. Experiments up to that moment had been carried on upon the lower animals, and in some of the European insane hospitals.

I believe the best results are to be attained in doses of from 0.65 gramme to one gramme, and it should be taken upon an empty stomach. I do not know of any literature upon this product in the English language. Several reports in German, however, have been made, and these are very promising.

221-223 FLYNN BLOCK.

INDICATIONS FOR TREATMENT OF GASTRIC HÆMORRHAGE.

By F. GREGORY CONNELL, M. D.,

SALIDA, COLO.,

ATTENDING SURGEON, D. & R. G. R. R. HOSPITAL; CONSULTING SURGEON, ST. VINCENT'S HOSPITAL, LEADVILLE.

In chronic hæmorrhages some form of medical treatment is indicated, the treatment being directed not so much toward the hæmorrhage as to the healing of the ulcer, the bleeding being merely a symptom of the ulceration.

If after a course of medical treatment, consisting of rest, diet, regimen, etc., the hæmorrhages and the other symptoms of the ulcer have disappeared, the case may be discharged as cured temporarily, but should be kept under surveillance for some time. On the other hand if, after a couple of months of medical treatment, either the small and repeated hæmorrhages or the signs and symptoms of the ulcer persist, then the chances are that a recovery will not be affected by the means adopted. Leube has said: "Ulcers that are not cured in four or five weeks by medical means will not be cured by longer treatment."

The question then presents itself, Shall the ulcer be allowed to remain, with the practical certainty of its becoming the exciting cause of an invalidism, more or less chronic if not including complications which may cause death or require an imperative operation at a time when the conditions will give rise to a much more grave prognosis than will such an operation at this time? Debove and Renault found in 100 cases of ulcer a perfect cure in 50, perforation in 13, foudroyant hæmatemesis in 5, tuberculosis in 20, inanition in 5, and other complications in 7. The answer, possibly involving some operative procedure aiming at the radical cure of the condition in the stomach before more hæmorrhages or other complications arise, must be worked out in each particular case.

In acute symptomatic hæmatemesis, it may be stated in a few words that prophylaxis is the only rational treatment of the vast majority of such cases; that is, in a case with a longer or shorter history of chronic ulcer, radical cure should be instituted *before* hæmorrhage or other complica-

most spontaneous lives. But when such an accident has been allowed to occur, radical procedures should be carried out as soon as possible, because, with our present knowledge of the pathology of the stomach, the findings in these cases do not encourage one in the belief that spontaneous or permanent cessation of the hæmorrhage is likely to occur.

When an ulcer exists with a thick hard base perhaps adherent to adjacent organs, with indurated edges, the blood vessels more or less isolated, with an opening involving but a part of the circumference of a large vessel, hæmorrhage from such a pathological condition as has been found to be present in many cases of acute symptomatic hæmatemesis is not as likely to cease spontaneously as it is to continue, and the sooner direct treatment is resorted to the better will be the prognosis.

In *acute non-symptomatic hæmatemesis*, the lines as to indications for treatment cannot be so closely drawn as in the symptomatic form. Prophylactic measures cannot be instituted. In the symptomatic, it is known, or is very presumable, that the hæmorrhages arise from a distinct, definite, and tangible pathological lesion, probably a chronic ulcer. In the non-symptomatic, the bleeding may originate from the same source as that of the symptomatic, but this is not usual. It more frequently springs from an acute ulcer, a fissure, an erosion of the mucous membrane, or from a condition which often cannot be located, even at autopsy in the most competent hands.

This lack of definite knowledge as to ætiology and pathology makes the indications for treatment necessarily unsettled and indefinite, and the best line of treatment more or less problematic. The fact that these hæmorrhages are many times found to be due to a general oozing of blood, as if the mucosa was weeping blood, and that a large percentage of them recover after palliative treatment, has tended toward making medical treatment the more commonly employed. But the fact that others succumb, and that these hæmorrhages can and do arise from distinct ulcers which have eroded large blood vessels, favors the employment of radical measures.

After *single acute hæmorrhages*, either symptomatic or non-symptomatic, medical treatment is usually advocated and instituted. Dieulafoy's procedure constitutes a marked exception, as he operates after a single bleeding if the blood lost equals or exceeds half a litre. He states that without surgical intervention, after a loss of that amount of blood, the patient will surely not survive, but if the amount of blood vomited is less,

the chances of recovery are fairly good without operation.

It has been conclusively proved, however, that the amount of blood vomited is no indication of the amount of hæmorrhage. A variable amount of blood may be passed into the bowel, only a portion of what is in the stomach may be vomited, or there may be no vomiting and the stomach remain full of blood. Nor may the origin be revealed by the vomited blood. Hæmorrhages sufficient to cause sudden death have been found to be of capillary origin, and in other cases the source has not been discovered even at autopsy.

Again, life and the hæmorrhages may be prolonged for weeks when even the large blood vessels have been opened, as may be seen by the tables of Savariaud.

As a matter of fact, little if anything is definitely known regarding this phase of the subject. There is no method of knowing whether a hæmorrhage is arterial or capillary. It is known that if arterial the chances of spontaneous arrest are slight, but that it may occur; that if capillary, the possibility of a natural cessation is more probable, but that it may continue and cause death. The only available means of attempting to decide upon these points before operation is the very unreliable clinical history, which should lead to a distinction into symptomatic and non-symptomatic acute hæmorrhages. The symptomatic, on account of a more pronounced pathology, will be more liable to repetition than the other, in which, as a rule, the pathological changes will not be so extensive.

From a careful study of cases it has been ascertained that the majority of acute single hæmorrhages are capillary oozings, and that many, but not all, cease as spontaneously as they began. Therefore it may be said that in acute single hæmatemesis, palliative treatment is indicated.

After *acute multiple hæmorrhages*, the question as to the most propitious time for interference will depend upon the history of the case, the character of the hæmorrhages, and the length of the interval. The moot point is whether surgery is indicated after a second hæmorrhage. After three or more bleedings, each profuse and succeeding one another rapidly, it is generally conceded that such an intervention is justifiable. The drawbacks to operating at this time are:

1. That the patient is in poor condition to withstand a severe major operation.
2. That cases do recover after repeated profuse attacks of hæmatemesis under palliative measures.

It will be remembered in considering these

drawbacks more carefully that to the best of our knowledge and belief the conditions will become worse, and in all probability death will supervene, if palliation alone is continued. The fact that death may follow an attempt to eliminate the cause of this poor condition—the bleeding—will not prevent the conscientious surgeon from doing what is clearly indicated, i. e., stopping the bleeding. The fact that the seat of the hæmorrhage is “internal” or “concealed” does not alter the underlying principle. Were it at the rectum, or at the mouth, an attempt would be made to secure the bleeding vessel.

Moullin, in this connection, says: “I may add that I have been consulted with a view to operating in three other cases of recent hæmatemesis, but the condition of the patients was so helpless that I would not take the responsibility, and they all died within twenty-four hours of my seeing them.”

In such cases the responsibility is not with the surgeon, but with the attending physician. Early transfusion, before surgery must be used as a last resort, is to be encouraged by every possible means. Yet it hardly seems fair to remove the last and only chance from the patient by refusing to operate because of this poor condition. Interference in such cases will do no harm, and the possibility of good resulting must be admitted. If only one in even a hundred can be saved, it would be well worth the effort.

There can be no doubt that cases of profuse and repeated hæmatemesis do recover after all attempts to stop the hæmorrhage have failed and the patient is supposed to be rapidly bleeding to death. Such instances appear in the literature of the subject, the satisfactory outcome being explicable by a decrease in strength and number of the heart beats and a lowering of the blood pressure, the results of syncope, aided by the fact that the coagulability of the blood is increased as its volume is decreased.

Such measures are evidently not to be considered as a realizable therapeutical method of producing hæmostasis, and when such a chain of circumstances results in a cessation of gastric hæmorrhage, not followed by death, it is certainly to be considered as a most fortunate accident.

To sum up: It may be stated as a general proposition that after a single hæmorrhage, palliative treatment is indicated; after three or more hæmorrhages, surgery should be resorted to. As to the proper line of treatment to be instituted after a second acute hæmatemesis, there can be found a great diversity of views.

Dieulafoy, again very radical, insists upon op-

erating if the hæmorrhage is repeated within twenty-four hours. Armstrong says: “Operate in all cases in which a second severe hæmorrhage occurs within seventy-two hours.” Mayo Robson advises: “After a second bleeding, even during the course of the hæmorrhage if the patient can stand it, or as soon after as his condition will permit, the operation to be done.” Bramwell, however, says of this advice: “If it is accepted and acted upon, operation for the arrest of hæmorrhage in cases of gastric ulcer will become of every day occurrence, with I fear . . . an increase rather than a decrease of the mortality.”

By far the greater number of operators have up to the present time advocated a waiting policy and a building up medical treatment, in the hope that the hæmorrhage would not be repeated. Russell says that while a second hæmorrhage by no means precludes recovery, it is a serious factor in prognosis, pointing, at least, to a considerable prolongation of the period of active symptoms.

This point, as to the proper mode of action after a second hæmorrhage, is still the burning question, so called by Rodman in 1900. We must continue to look to the future for a better and clearer light upon this part of the subject.

From the limited experience upon which this paper is based no conclusion of value can be deduced, but from the literature we are inclined to concur with Rodman, in advocating that “something should be done to prevent, what are reasonably certain, other hæmorrhages;” and we can reiterate his statement: “I am thoroughly convinced, from a careful study of all reported cases up to date, that none was operated too early, but many were too late.”

Bequest to the College of Physicians and Surgeons.—The will of the late Dr. William E. Griffiths, of 320 Schermerhorn Street, was filed for probate in the Surrogate's office on March 17th. By the terms of the will, Dr. Griffiths gives his household furniture to his mother-in-law, Mrs. Jane Snyder, and legacies to various cousins. To the Brooklyn Institute, engravings by Cláudia Stella of the date of 1640, after paintings by Poussin, a maple top stand made about 1790, and formerly used by his great uncle, Vice-chancellor McCoun, also a box of valuable minerals are given. All the residue of his estate, including his valuable property at the corner of Schermerhorn and Nevins Streets, he leaves in trust for the benefit of his friends George B. Little and Mrs. Harriet J. E. Sheldon, the former to receive four fifths of the income and the latter one fifth, and upon the death of both of these life tenants the whole residue goes to the College of Physicians and Surgeons of Columbia University.

THE DIAGNOSIS AND TREATMENT OF ACUTE PELVIC PERITONITIS OF GONORRHEAL ORIGIN.*

By BROOKE M. ANSPACH, M. D.,

PHILADELPHIA.

The gonococcus, in the production of peritonitis, usually confines its effort to the pelvis; the general peritoneal cavity is but rarely invaded; even though it is, the prognosis of this form of general peritonitis contrasted with other forms is favorable.

It is equally true that pelvic peritonitis due to the gonococcus is not often fatal. Although there may be permanent disability and chronic invalidism as a consequence, there is not *per se* a fatal result. Because of these facts acute pelvic peritonitis of gonorrhœal origin when confined to the pelvis may well be regarded as not immediately dangerous to life and as amenable to palliative treatment.

This form of peritonitis, however, bears in its clinical manifestation a resemblance close enough to appendicitis to make its diagnosis a matter of great importance. Conservatism in the one is justifiable and safe while in the other it is conducive to serious results.

There is probably no intraperitoneal inflammation so treacherous as that of the vermiform appendix; an apparently mild case may quickly become lethal. Sometimes the diagnosis is not made until autopsy or operation. In those cases of peritonitis in which the origin is not evident clinically, the appendix has been very often the seat of disease.

This is without doubt very generally recognized and the physician to-day is more on his guard against overlooking or misjudging appendicitis than any other intraperitoneal inflammation.

It is important then to distinguish acute pelvic peritonitis of gonorrhœal origin from acute appendicitis; and by acute pelvic peritonitis should be understood the inflammatory reaction which marks the initial passage of gonorrhœal pus to the pelvic peritonæum.¹

The subsequent attacks when the tube has begun to close with the formation of pyosalpinx may be just as acute as the primary ones, but usually the pelvic mass found upon bimanual palpation in the secondary attack, makes the diag-

nosis more or less evident. In the cases under consideration, there may be at first no pronounced pelvic mass; a woman previously free from acute pelvic disturbance is seized with sharp pain in the lower abdomen, maybe worse on one or the other side, associated with constipation, distention of the abdomen, fever, increased pulse rate, and more or less prostration.

Such symptoms very often indicate an acute inflammation of the appendix. It is to be remembered moreover that pelvic peritonitis may be and often is accompanied by appendicitis.

When appendicitis exists either alone or with inflammatory affections of the annexa, an operation in the majority of cases is advisable. On the other hand, in acute pelvic peritonitis due to gonococcus infection, operation had better be postponed. In distinguishing between these two, the previous history of the patient often indicates a correct conclusion. Although gonorrhœa in its early stage may escape the observation of the female, inquiries as to the existence of vesical irritability, leucorrhœa, the origin of the symptoms with reference to the marital state, and with relation to the menstrual period, frequently elicit ground for a tentative opinion.

Inspection of the parts, the orifices of Skene's glands, the vulvovaginal glands, and the cervix, gives additional evidence, oftentimes the most positive. Inquiry should be made concerning the classical symptoms of appendicitis. The history of repeated attacks, of habitual overeating, and of chronic indigestion together with the character and location of the pain, as a rule, afford a satisfactory clue. A comparative table of symptoms may be useful.

Gonococcus Pelvic Peritonitis.

History. Leucorrhœa or vesical irritability soon after marriage or suspicious intercourse.

Onset. At or directly after a menstrual period.

Pain in lower abdomen—worse perhaps on one or other side.

Gastrointestinal Symptoms. Nausea, vomiting, constipation, less marked.

Appendicitis.

History. Previous similar attacks. Habitual overeating, chronic intestinal indigestion.

Onset. After indiscretion in diet.

Pain beginning in epigastrium—not well localized at first—later localized to appendiceal region.

Gastrointestinal Symptoms. Nausea, vomiting, constipation, etc., more marked.

There is not so much to be learned by bimanual palpation as would be expected. Because of tenderness and rigidity a satisfactory examination of the tubes and ovaries without ether is frequently impossible. The position of the uterus, however, can be determined as well as the presence or absence of fixation of that organ. At an early stage there is little or no fixation and lit-

* Read before the Philadelphia County Medical Society, December 14, 1904.

¹ There is, of course, another form of pelvic peritonitis—viz., that produced by pyogenic organisms, notably the streptococcus. The history, however, in this form clearly indicates a source of pyogenic infection—the symptoms are all more severe than in the gonorrhœal form, and it very rarely occurs except after evacuation of the pregnant uterus.

the pelvic exudate. So that the examination, although admittedly unsatisfactory, may be entirely negative. In the cases forming the basis of this paper, the initial examination was negative, although the annexa could not be definitely palpated; the uterus was freely movable and there was entire absence of any well defined induration. Bimanual examination in cases of acute appendicitis is also usually negative in the absence of pelvic complications. When the appendix hangs over the pelvic brim a mass may sometimes be felt, but this is rather exceptional unless there is an appendiceal abscess.

Abdominal tenderness and rigidity are present over the entire lower abdomen in acute pelvic peritonitis in contrast to the more localized tenderness and rigidity seen in appendicitis. Occasionally in gonococcus pelvic peritonitis, there is more pain and tenderness on one or the other side; if that side happens to be the right, the resemblance to appendicitis is increased.

Tenderness of appendiceal origin may sometimes be elicited upon bimanual palpation when the right annexa are normal by drawing the uterus downwards and to the left side. This supposedly is due to traction upon the appendix by a fold of peritonæum running between the broad ligament and the mesoappendix.

There seems to be no question that acute appendicitis, especially when it is severe enough to be confounded with acute pelvic peritonitis, should be exposed to operation immediately. It is otherwise with acute gonorrhoeal pelvic peritonitis. Experience has shown that these cases do well if kept quiet in bed and given salines, copious douches of hot salt solution, and applications of heat to the abdomen. Under such expectant treatment the temperature and pulse-rate gradually approach the normal; there is less abdominal pain and distention. All of the subjective symptoms may disappear in four or five days.

At this late stage bimanual examination finds more or less fixation of the uterus, pelvic exudate and enlargement of the annexa. Operation during the acute attack, therefore, appears to be unwarranted and clinical experience bears out this view. Operation could not be followed by any better immediate result than palliation and during the acute stage it would expose the woman to acute general peritonitis.

Later on the gonorrhoeal pus becomes less infectious or inert; the economy has reacted to the toxic products thrown into the circulation, the extent of inflammatory involvement is recognized with less difficulty, and there is not so much like-

lihood of leaving tissues behind which will subsequently give trouble.

One cannot afford to stop here in considering the treatment of this disease, for there is a possibility in every case that the infection may become general. In such an event the danger is much greater and the question of operative interference is of more moment. If the peritonitis does become general, it is best to perform laparotomy without delay.

Hunner, who has collected a series of eighteen cases of general gonococcus peritonitis in which the diagnosis was substantiated by bacteriological evidence, found eleven recoveries and two deaths in thirteen cases subjected to operation; and five deaths in five cases not operated in. He has further reported twenty-one cases in which the diagnosis was positive, but based upon clinical evidence alone; in which there were eight recoveries and three deaths in eleven cases submitted to operation; and eight recoveries and two deaths in ten cases treated expectantly.

He is doubtful as to the advisability of operation, but well says that the exclusion of other sources of infection in these serious cases is sometimes impossible. From the statistics Hunner himself quotes one can see that in the cases positively diagnosed as gonorrhoeal peritonitis there was a large percentage of recoveries following operation (eleven recoveries and two deaths in thirteen cases operated in; five deaths in five cases treated expectantly).

If an opinion is based on this fact, and surely this is a more reliable criterion than the result in those cases in which there was no bacteriological confirmation, the question of operative interference must be answered in the affirmative. Therefore, in gonorrhoeal pelvic peritonitis if distention, vomiting, tenderness, and rigidity show a constantly increasing tendency, if peristalsis diminishes, if the facies of septic intoxication appears, operation is advisable. If upon opening the abdomen the diagnosis of gonorrhoeal peritonitis is confirmed it is best to confine one's efforts to the evacuation of any intraperitoneal collections of fluid. According to Hunner it does no good to attempt to remove fibrinous deposits upon the bowel or to separate adhesions; this is often productive of harm by opening up new avenues for infection and may result in the formation of new adhesions and postoperative obstruction. The diseased tubes, he says, if they contain appreciable quantities of pus should be removed. While the social condition of the woman and her childbearing proclivities must be considered in such cases and no rule can be laid down, I believe

that it is better to remove both tubes if they contain pus, whether they have gone on to the formation of pyosalpinx or not. In other intra-abdominal infections, the source of the trouble requires removal for the immediate good of the patient and why should it not be so here? Moreover, if the tubes are allowed to remain, it is quite probable that they will either subsequently give trouble or that they will be functionally useless.

When the peritonitis remains confined to the pelvis under the palliative measures given, the symptoms will subside, but there remain structural changes which may and usually do call for operative interference.

The temperature of the patient returns to normal, the pulse rate diminishes, and there is no spontaneous pain. At this time a bimanual examination is more satisfactory and gross inflammatory alterations are found about the annexa. Whether an operation should be performed at this time or not and the extent and variety of such operation is an entirely different question from those we have been discussing. Although conservatism is advisable in many of the less serious cases of suppurative gonorrhoeal affections of the annexa, these patients as a class would be better treated if they were exposed to operation as soon after an initial attack of acute pelvic peritonitis as structural lesions could be recognized in the pelvis. Certainly at this time there would be less need of a complete or very extensive operation.

I have selected the following cases, all occurring during the past year, as types of the condition under consideration:

CASE I.—R. H., single, aged 25 years. Two months before admission had sexual intercourse. One month before admission began to suffer from profuse irritating discharge. Present attack began three days before admission at the close of her last menstrual period. Sharp pain in lower abdomen, especially marked on the left side. Admitted May 10, 1904. Temperature, 100°; pulse, 108; respiration, 20. Abdomen distended, marked tenderness and rigidity over lower abdomen, slight nausea, constipation. Condition after 36 hours' treatment: Temperature, 100°; pulse, 120; respiration, 24. Pelvic examination, bilateral pyosalpinx. May 11, 1904, operation, right salpingectomy, left salpingo-oophorectomy. Smears from peritonæum show gonococcus. Recovery complicated by suppuration of right ovary.

CASE II.—M. S., single, aged 21 years. At age of 19 years had miscarriage, 6 months' child. September, 1903, had another miscarriage. Present attack followed closely upon last menstrual period, November 23rd to 27th. Sharp pain in lower abdomen. Admitted November 29, 1903. Temperature, 103°; pulse, 132; respiration, 40.

Abdomen distended, marked tenderness and rigidity, peristalsis diminished, slight nausea, constipation. Condition after five days' treatment: Temperature, 99°; pulse, 100; respiration, 24. Pelvic examination, bilateral tuboovarian masses. Skene's glands, vulvovaginal glands show macula gonorrhoea. Operation, December 3, 1904. Bilateral salpingectomy. Uneventful recovery.

CASE III.—A. S., single, aged 20 years. For past two years has had leucorrhoeal discharge. Last menstrual period ended November 1, 1903. Attack began November 4, 1903. At this time discharge ceased; sharp pain in lower abdomen, continued and grew worse until November 17, 1903, when it was so severe that she was compelled to go to bed. Admitted November 18, 1903. Temperature, 103°; pulse, 110; respiration, 28. Abdomen distended, pain and tenderness and rigidity in lower quadrant, constipation, nausea. Condition after six days' treatment: Temperature, pulse, and respiration normal. Pelvic examination, bilateral pyosalpinx, Skene's glands, vulvovaginal glands show macula gonorrhoea. Operation November 30, 1903, left salpingo-oophorectomy, right salpingectomy. Recovery.

The first case illustrates the difficulty sometimes experienced in deciding when to dispense with expectant treatment and enter the abdomen. After 36 hours of rest in bed, the use of salines and hot douches, the symptoms seemed to indicate that the infection was becoming general; accordingly celiotomy was performed. The infection was found entirely confined to the pelvis and it would have been better to postpone the operation until the acute stage had passed. As a result of this interference during the active period the right ovary which was conserved with the uterus underwent suppuration; the incision also broke down. In both of the other cases the healing was *per primam* and the convalescence was in every way normal.

In conclusion I wish to thank Dr. Clark for the privilege of reporting these cases, all of which occurred in his service at the University Hospital.

2049 CHESTNUT STREET.

Eastern Colorado Medical Association.—Physicians from Morgan, Washington, and Yuma counties met in Dray on March 11th and organized the Eastern Colorado Medical Association. The officers of the association are: President, Dr. E. D. McGill, of Wray; vice-president, Dr. E. J. Bales, of Wray; secretary, Dr. George E. Bilsborrow, of Yuma; treasurer, Dr. N. J. Phelan, of Akron; censors, Dr. A. L. Howe, of Wray; Dr. N. J. Phelan, of Akron; Dr. Turner, of Brush. The next meeting of the association will be held at Akron, April 4th. This initial meeting was called at the instance of Dr. McGill, and the attendance was good.

AN APPARENT CURE OF ADDISON'S DISEASE WITH YEAST.

The diversity of uses to which yeast may be put as a remedy seems still to be growing. Dr. Dumas, of Lédignan (*Echo médical des Cévennes*, 1904, p. 245; *Revue française de médecine et de chirurgie*, February 6th), records a case in which Addison's disease was apparently arrested in its manifestations by the use of the drug. Before proceeding to the points of the case, we cannot forbear calling attention to some remarks of Dr. Dumas's that seem to proclaim him to be the possessor of the humor proper to a country doctor. Remarking that a single cure is a small matter, he applies to therapeutics the legal maxim *unus testis nullus testis*. He must have had a glimmering of a certain Aldine Club dinner joke at the expense of the guest of the occasion, Sir Conan Doyle, when he said, apropos of his making a diagnosis at the first glance, that this phrase from a song was applicable: *Rien qu'en voyant votre habit militaire, j'ai deviné que vous étiez soldat*. Finally, justifying the use of yeast even if it can only prolong life for a few weeks, he says: *Au fond, nous sommes tous des prolongés*.

But to the case. The patient was a widow, fifty-eight years old, who had been out of health for about three months when she applied to him for advice. She had come in a carriage from her

home, distant about five miles, and she entered leaning on the arms of her son and his wife. She sank to her seat exhausted. This exhaustion, coupled with the deep bronzing of her skin and her vacuous expression, led Dr. Dumas to an immediate diagnosis, as has been intimated, but he took the precaution of excluding a pigmentary syphilide, discoloration with silver nitrate, malarial cachexia, and diabetes. He prescribed a coffeespoonful of brewer's yeast, to be taken fifteen minutes before each meal, at the same time advising a diet of milk and vegetables. A fortnight later the patient's condition was improved, and at the end of another month she was to all appearances perfectly well. However, Dr. Dumas did not judge it wise to stop the use of the remedy, but he foresees that it will have to be stopped sooner or later; then, if a relapse occurs, he will resume it. He argues that suppression of the poisoning of suprarenal origin favors a return of the adrenals to their normal state, but he realizes that a permanent cure is not to be expected if the disease is due to organic degeneration of the suprarenals. That, however, he remarks, is quite as true when the suprarenal gland itself, fresh or desiccated, is administered.

SOME RECENT AMERICAN STUDIES OF CANCER.

In our issue for January 21st, commenting upon the experimental transmission of malignant disease among mice in the Gratwick Laboratory of the University of Buffalo, we intimated that the exact nature of the tumors engendered in the inoculated mice was up to that time somewhat uncertain, adding that they appeared to be sarcomatous rather than carcinomatous. The experiments were the work of the Cancer Laboratory of the New York State Department of Health. In a letter recently received by us from a prominent member of the staff of that laboratory the writer says: "I might state to you that this tumor has been seen by Orth, Welch, Councilman, and I might enumerate a long list of other authorities, and in no case has any one raised the question that this tumor is distinctly a malignant adenocarcinoma." Adenocarcinoma is a form of neoplasm described by Professor Jensen, of Copenhagen, from whom the Buffalo laboratory received its first infected mice. In some cases the

mice have recovered spontaneously, and their serum has been employed with a curative, or at least inhibitory, effect upon other infected mice. This being the case, it must be admitted, we think, that the experiments furnish some ground for hope that an efficient serum treatment of malignant disease may yet be elaborated.

It may be possible to reconcile all this with the view of Jensen's experiments presented by Dr. Edward H. Nichols, of the research committee of the Caroline Brewer Croft Cancer Commission, in the commission's third report, recently issued by the Medical School of Harvard University. "In no case," says Dr. Nichols, "has any organism been cultivated from the experimental tumors. All observers agree that the tumors are true transplantations, and that the tumors develop from proliferation of the transplanted cells and not from infection of the fixed cells of the inoculated animals. When tumor cells are excluded by filtering, in no case does the injected cancer juice cause tumors."

A priori, the parasitic nature of cancer seems plausible, and there are many who contend, not only that the disease is caused by a parasite, but, more specifically, that the parasite is a protozoon. But Dr. Nichols makes out a strong argument against the parasitic theory. He remarks that the alleged relative increase of cancer in recent years is disputed and has not been proved, and he thinks that local causes of the origin of cancer are improbable. The metastases in cancer, he avers, although they follow the same routes as those of infectious diseases, are of absolutely different origin and constitute the strongest theoretical argument against an infectious or parasitic nature of the disease. The cachexia, he thinks, is probably not entirely due to the character of the cancer itself, but is often dependent on secondary bacterial infection. He declares that there is no proof of the transfer of cancer from one human being to another by contact, and, although its transplantation from one animal to another of the same species is well verified, the production by any known parasite of epithelial proliferation analogous to that of cancer has not been demonstrated.

Between the confidence of the Buffalo school in the parasitic, even protozoan, origin of cancer and the negative attitude of the Boston school, we must

confess ourselves to be at present in a state of the greatest doubt, but we feel well assured that continued investigation will before long bring us to some positive conviction, and each group of investigators will be entitled to share in the credit of the result.

THE PREVENTION OF CEREBROSPINAL MENINGITIS.

We are face to face in New York with a degree of prevalence of this grave disease that, while perhaps it does not warrant alarm, certainly gives occasion for anxiety. During the week ending on February 25th it caused forty-nine deaths, during the succeeding week sixty, during the next week seventy-six, and during the week ending on March 18th seventy-six. We know that the Health Department is fully alive to the necessity of doing everything in its power in the way of limiting the prevalence of the disease, and we have no doubt that it is doing it. But its field of action is necessarily restricted; its efforts should be supplemented by all possible care on the part of individuals, as is always the case in matters of sanitation.

What, then, can the individual accomplish? It is the opinion of not a few of our rhinologists that the germ of cerebrospinal meningitis is taken into the nasal passages and thence gains access to the cranial cavity through the cribriform plate of the ethmoid bone. On this theory they advise the intranasal employment of germicides. We do not understand that they advocate strong applications or those that are difficult for an intelligent person to use; a simple saturated solution of boric acid, sprayed into the nasal passages twice a day, the throat being at the same time treated with the same solution, is thought to be sufficient, so far as concerns means that may safely be put into the hands of the public.

Much might be said in support of the belief that such simple measures would prove decidedly efficacious as a prophylactic of some others of the infectious diseases, and there can be no doubt that the care of the mouth and nose is generally neglected among persons who in other respects are commendably careful. Many of the pathogenic microorganisms are doubtless temporarily

arrested in the mouth and nose, and might readily be rendered innocuous before reaching more vital parts.

CEREBROSPINAL MENINGITIS AND TYPHUS FEVER.

There is a singular resemblance between the symptoms of cerebrospinal meningitis, which is now of such grave interest to residents of New York, and those of typhus fever that must have led, we think, to frequent confusion in the days before exact clinical diagnosis. Both are believed to be caused by inhalation of a specific germ, both are infectious and contagious, are characterized by similar eruptions, and resemble each other in their onset with fever, nausea, vomiting, delirium, coma, and convulsions. There is of each a fulminating form causing death in a few hours. Both diseases favor dirty and overcrowded places. Apart from the result of lumbar puncture, a procedure unknown until quite recently, the principal diagnostic point seems to have been the facies of typhus; the expression being described as drunken or besotted, while the countenance in meningitis is livid. A century ago, however, a besotted expression must have been common among the class most afflicted by typhus. When we note, moreover, that any clear history of meningitis is lacking previous to the beginning of the last century, while the records teem with accounts of jail fever, ship fever, etc., it is hard to escape the conclusion that many supposed cases of the latter were really cases of cerebrospinal meningitis.

ON PATHOLOGICAL HEREDITY.

The problem of heredity has occupied the critical minds from ancient times. Continuity of life from parents to children, transmission of parental features in physical and mental spheres from generation to generation, is undoubtedly a highly complex phenomenon which as yet is not fully understood. The first scientific work based upon embryological researches begins with von Baer, in the first half of the nineteenth century. Herbert Spencer's works and Darwin's biological observations contributed considerably to the subject, but the most creditable pathological inves-

tigations began with Morel. Since then various biologists have busied themselves with the effects of hereditary influences from the normal and pathological standpoints.

The value assigned to heredity outside of other factors, such, for example, as the capacity of adaptation to changing condition or other factors, cannot be overestimated. In normal conditions the potency of heredity in regard to particular traits and features is of common observation. To the sociologist and physician the study of morbid hereditary influences produced by various deleterious agents is a matter of paramount importance, as the thorough knowledge of their effects upon the human organism and individual tissues and organs will place in their hands powerful means of prevention. It has always been a matter of great practical interest to trace out and to understand the effect of alcoholism, syphilis, tuberculosis, plumbism, or other well known chronic intoxications on the individual and on his progeny.

The evolution of sexual cells in the ovaries and testes is diverted from its normal course when noxious agencies, like alcohol, etc., are introduced into the system. Quite recently it has been proved that the sperm, or germ, cells and the impregnated ovum become affected independently when the parent organism is under the influence of a toxic agent. Facts are abundant in literature testifying to the rôle of noxious agencies in pregnancy. Abortions are frequent; sterility and premature labor are equally frequent and sometimes their frequency is so pronounced that the fear of depopulation is maintained with good reason. According to Legrain's carefully collected personal statistics, over one third of the pregnancies ended with premature labor. But there is a problem of a more profound value to be considered, viz., if the child is born at full term, what will be the stigmata of the inherited pathological influence, and can they be transmitted to several generations? Among all the organs and tissues of our system, the most susceptible to the effect of various extraneous factors is the cerebrospinal system, and this great organ is the bearer of hereditary endowments of various character. It is striking to note that precisely in the

cerebral sphere deviations from normal functions are observed. Epilepsy, meningeal symptoms with or without convulsions, idiocy and imbecility with or without physical stigmata of degeneracy, all degrees of mental degeneracy from simple want of cerebral equilibrium, general nervous irritability, obsessions of various nature, or other varieties of neuropathy showing a special fragility of the nervous system, to total mental debility or insanities—all these facts are of such a frequent occurrence in cases of alcoholic indulgence in parents that no further comment is needed. Also examples of acute intoxication during or shortly before the sexual intercourse followed by these results are abundant. The French school especially, with Pinel and Esquirol of the older times, Bourneville, Legrain, Magnan, and Voisin among the later observers—elaborated the question of alcoholism and heredity. Bourneville, in 1896, investigated 1,000 idiots and found alcoholic parentage in sixty-two per cent. According to Roubinovitch, the distinguished alienist of Ste.-Anne's Asylum, of Paris, in over ninety per cent. of cases of degeneracy manifesting itself in idiocy, imbecility, or various mental derangements, parental alcoholism, and especially that of the father, was the sole factor. Dr. A. MacNicholl published in the *Quarterly Journal of Inebriety* in 1902 an interesting record showing the degenerative effect of alcohol on the progeny for four successive degenerations.

Legrain's investigations show an extremely interesting and significant point concerning the age at which mental disturbances begin to develop. They are usually precocious, affecting the unfortunate victims of parental excesses at the age of twenty and sometimes earlier. In quite a large number of families he observed insanities in infancy or at puberty. In the majority of his cases, viz., fifty-seven per cent., the subjects were idiots and imbeciles, and 44.40 per cent. were classified as insane. The effect of alcoholic heredity is therefore considerable, and with good reason alcohol occupies the first place among all the poisonous or noxious factors capable of producing degenerative conditions in races, individuals, tissues, organs, and cells, which are transmitted to several successive generations.

Next in order comes syphilis. We find here, again, the nervous system to be the greatest sufferer. Idiocy and imbecility are not infrequent consequences of parental transmission to the offspring. We are now familiar with occurrences of tabes or other nervous diseases acquired from inherited syphilis. In the columns of this journal some time ago the writer reported a case of juvenile tabes where specific infection could be traced to the parents. Congenital internal hydrocephalus, various meningeal manifestations, and malformations of brain and cord, such as meningocele, encephalocele, anencephaly, and spina bifida, can all be traced to inherited syphilis. Tuberculosis, various chronic intoxications, and diabetes may all lead to degenerative stigmata in the progeny, particularly in the domain of the nervous system.

The above enumerated facts regarding the maternal and paternal infections and intoxications are, in my estimation, of extraordinary practical importance. They call for our most solicitous attention and care. The safety and the existence itself of society are intimately associated with and depend upon the degree of attention we may give to this side of our life. Inauguration of special regulations concerning marriages is indicated. Efficient hygienic and prophylactic measures concerning various intoxications must be outlined and strictly observed. The evil arising from those factors and the racial extinction with which society is threatened should be unceasingly indicated and emphasized in the press and taught in schools. No man is in a more favorable position to understand and realize the importance of the subject than the physician. It is therefore the physician who is expected to bend all his efforts to spread this knowledge and call the attention of every thinking man to the great problem of pathological heredity. ALFRED GORDON.

THE UNIVERSITY OF PENNSYLVANIA MEDICAL BULLETIN.

This monthly publication, now in its eighteenth volume, has been the medium in which many notable contributions to the advance of scientific medicine have been published, and its recent issues give promise of its long continuing to be a vehicle of the very highest order. The January

number is perhaps conspicuously noticeable by virtue of its containing several valuable articles on neurological subjects. The *Bulletin* is edited by Dr. Charles H. Frazier and Dr. William Pepper.

EXTENSIVE INJURY IN DEFLOURATION.

Reports of injury of the woman in the first coitus are not very uncommon, but such an extensive injury of this sort as is reported by Cealac, of Bucharest (*Revista de chirurgia*, 1904, No. 6; *Zentralblatt für Gynäkologie*, March 11th), must be rare. The woman, twenty-two years old, is described as of delicate build, and her husband's penis was found to be abnormally large. On the nuptial night he made three fruitless efforts at intercourse. In the fourth attempt he perforated the rectovaginal septum, making an opening an inch long, and lacerated the perineum. The woman stated that she had lost a good deal of blood at the time of receiving the injury.

A DANGEROUS PREPARATION.

At the instance of the editor of the *American Druggist*, an analysis has been made of a preparation advertised in certain medical journals under the name of Bonn's passiflora tablets, and the astounding fact is revealed that the tablets contain a large percentage of acetanilide, though there is no mention of this substance in the advertising matter of the company that markets them.

Obituary.

MEDICAL DIRECTOR GEORGE A. BRIGHT, OF THE NAVY.

Dr. Bright, who died in Washington last week, was a native of the State of Maine. He graduated from the Medical School of Harvard University, served on the house staff of the Massachusetts General Hospital, and began private practice in Concord, New Hampshire. In a few months, the civil war having broken out, he entered the navy as an acting assistant surgeon. At the close of the war he joined the regular medical corps of the navy, and, rising by the usual course of promotion, reached the rank of medical director. Not long ago he was retired with the rank of rear admiral. He was a man of engaging personality, and his career in the navy was long and creditable.

The Ladies' Auxiliary of the Society of the Lying-in Hospital offer a reading by Mrs. Le Moyne at Sherry's on Thursday afternoon, March 30th. The proceeds will go into a fund to be used among the East Side poor.

News Items.

Society Meetings for the Coming Week:

MONDAY, March 27th.—Medical Society of the County of New York; Lawrence, Mass., Medical Club (private); Cambridge, Mass., Society for Medical Improvement; Baltimore Medical Association.

TUESDAY, March 28th.—New York Medical Union (private); Metropolitan Medical Society, New York (private); Buffalo Academy of Medicine (Section in Obstetrics and Gynecology); Richmond, Va., Academy of Medicine and Surgery; Rome, N. Y., Medical Society; Boston Society of Medical Sciences (private).

WEDNESDAY, March 29th.—Auburn, N. Y., City Medical Association; Berkshire, Mass., District Medical Society (Pittsfield).

SATURDAY, April 1st.—Manhattan Medical and Surgical Society, New York (private); Miller's River, Mass., Medical Society.

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending March 18, 1905:

	March 18.		March 11.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	383	9	349	10
Diphtheria and croup	321	34	296	26
Scarlet fever	249	25	270	19
Smallpox	1	1	1	..
Chickenpox	149	..	159	..
Tuberculosis	505	198	480	183
Typhoid fever	31	7	30	9
Cerebrospinal meningitis	135	72	..	76
	1,774	346	1,585	323

New York Physician Made a Knight.—At the recommendation of the Italian Minister of Foreign Affairs the King of Italy has made Dr. Antonio Fanoni, of New York, a Knight (Cavaliere) of the Order of the Crown.

Change of Address.—William W. Bostwick, M. D., late first assistant physician Sailors' Snug Harbor, has begun private practice at 551 West One Hundred and Fifty-second Street.

St. Vincent's Hospital, Staten Island.—At the last meeting of the medical board of St. Vincent's Hospital, West New Brighton, Dr. E. D. Wisely, of Port Richmond, was appointed medical attendant to succeed Dr. James L. Devlin, of New Dorp, who resigned on account of the distant location of the hospital from his home. Dr. E. C. Baldwin, of Fort Wadsworth, was appointed pathologist. Dr. W. W. Gilfillian, of Manhattan, was appointed consulting oculist.

A New Training School for Nurses.—A training school for nurses has been started at the new French Hospital, 450 West Thirty-fourth Street, New York. The course is to extend through two years, including a two months' probationary term, and will include experience in obstetrics and diseases of children, as well as all branches of general medicine, surgery, and gynecology. Applicants are not required to speak French, but will receive instruction in the language as a part of their course. The hospital has a capacity of about 130 beds, including private rooms, and both building and equipment are thoroughly modern.

Small Fire in Hospital.—A small fire started on March 17th in the office of the Presbyterian Hospital at 75 East Seventieth Street. It was put out with a hand extinguisher before it had opportunity to spread, and without causing any alarm among the occupants of the building.

Eastern Medical Society.—This society will give a concert and ball on the evening of March 28th at Terrace Garden. The object of the affair is a twofold one, to bring about a social meeting of the members of the society with other members of the medical profession, as well as with those of the allied professions, and to raise funds for the enlargement of the library so as to meet the scientific needs of the professional brethren of the East Side.

Hospital Saturday and Sunday Association.—Charles Lanier, of 50 Cedar Street, general treasurer of the Hospital Saturday and Sunday Association, is desirous that all treasurers of churches or trade auxiliaries who have not yet made their returns to him should do so at their earliest convenience, as the time is approaching when the distributing committee will be called upon to divide the general fund collected. Not only was the collection taken in the churches on the last Hospital Sunday nearly double the amount realized in the previous year, but the aggregate from all sources, which then was barely \$75,000, is now above \$90,000, and it is confidently believed that another year will bring it to the \$100,000 mark.

A Farewell Dinner to Dr. Osler.—Invitations are out for a dinner in honor of Dr. William Osler, to be given at the Waldorf-Astoria, New York, on the evening of Tuesday, May 2nd. The committee is a large one, including well known physicians of Baltimore, Montreal, Toronto, Chicago, St. Louis, Providence, Boston, St. Paul, Minneapolis, New Haven, Buffalo, New Orleans, San Francisco, Augusta, Ga., Ann Arbor, Syracuse, Cincinnati, Albany, Detroit, Richmond, Memphis, Philadelphia, Washington, Pittsburgh, Cleveland, Rochester, Louisville, Denver, Colorado Springs, Saranac Lake, Portland, Me., Nashville, and New York—a body of men, eighty in all, thoroughly representative of the profession. The gathering will undoubtedly be a large one, and the distinguished and amiable guest of the occasion cannot but carry from it to the new scene of his activities the pleasantest of memories.

J. Hood Wright Hospital in Need.—According to the forty-first annual report of the J. Hood Wright Memorial Hospital, just issued, there is a constant increase of service accompanied by a coincident increase in cost of maintenance, without a corresponding increase in reliable income. Taking the records for the last two years, the increase is 231 in patients treated in hospital; an increase of 509 in the number of patients in the emergency ward; 657 increase in days' treatment of patients; 319 increase in days' free treatment; 282 increase in days' treatment partly paid for; 529 increase of patients in dispensary; 358 increase of visits to dispensary; 27 increase in ambulance calls; and 145 increase in number of

operations. The question of increased cost of maintenance without a reliable and corresponding income is regarded as of very serious moment. By the efforts of patrons and members, with the addition of sundry gifts from friends, the hospital has been able to close the year and pay all bills without leaving a deficit. The treasurer's statement, however, shows that it has but \$671.33 available for current expenses with which to begin the new year.

Obituary Note.—Dr. Amos Harrison Brundage, who died Sunday at his home, 1073 Bushwick Avenue, Brooklyn, in his seventy-seventh year, was one of the founders of the New York State Medical Society. He was born at Benton, Pa., and after graduating from the Central College at McGrawville, N. Y., he taught school for several years in Pennsylvania, at the same time being postmaster at Fleetville and conducting a drug store. He studied medicine, and in 1855 graduated from the medical college of the New York University. When the civil war broke out he joined the One Hundred and Seventy-ninth Regiment, New York Volunteers, and later was acting surgeon of the Sixth New York Regiment of cavalry under General Sheridan, and was present at the surrender of General Lee at Appomattox. At the close of the war he moved to Cohoes, N. Y., and in 1881 he settled in Brooklyn. He was a member of the Brooklyn Medical Society. He is survived by two sons, Dr. Albert N. Brundage, of Brooklyn, and the Reverend Henry E. Brundage, of Denver, Col.

The Meningitis Commission.—The commission to investigate cerebrospinal meningitis, appointed by Health Commissioner Darlington, had its first meeting on March 21st, in the Health Department building at Fifty-fifth Street and Sixth Avenue. The commission consists of Dr. W. F. Polk, Dr. W. B. James, Dr. W. T. Northrup, Dr. Simon Flexner, Dr. J. F. Van Cott, Dr. E. K. Dunham, and Dr. William K. Draper. Dr. Polk, who is dean of the Cornell Medical School, has not yet accepted the appointment. He was the only member not in attendance. His place as chairman of the commission was filled, temporarily, by Dr. James. Dr. Draper was appointed secretary. The commission spent some time studying maps of the city with regard to the prevalence of the disease in certain localities, and in considering the conditions peculiar to those localities. They also had before them the tabulated statistics of the disease for several years back. Dr. Northrup, Dr. James, and Dr. Draper, representing the clinical section, and Dr. Flexner, Dr. Van Cott, and Dr. Dunham, the bacteriological section, then considered in groups the points to be investigated under each head. The commission decided to issue cards to doctors in hospitals, with blanks to be filled in with data, as was done by the pneumonia commission last year. While the final list of questions to be asked in these cards was not settled, the commission will want to know, from the bacteriological standpoint, what are the evidences of communicability and what is known of the biology of the disease bacilli, with reference to differentiation, agglu-

tionation, and pathogenesis. Clinically they will inquire about the effect of drying on the bacilli and viability in spray, as bearing on isolation and infection. Complete information about the patients' surroundings and the conditions under which they were stricken with the disease will also be collected. It is probable that the scope of the investigation will be world wide and that information will be sought from hospitals all over the globe. This commission is the second of the kind appointed in New York. The pneumonia commission, appointed last year, is still at work, but expects to publish the results of its labors in a short time.

PHILADELPHIA.

Changes of Address.—Dr. John Hamilton Small, to 914 South Forty-eighth Street; Dr. Robert N. Keely, to Brown's Mills in the Pines, N. J.; Dr. H. R. M. Landis, to 130 South Twenty-third Street.

Marriage.—Dr. Herbert Norris and Miss Harriet W. Frothingham were married on March 15th. After a wedding trip in Europe and a summer spent in Nova Scotia, Dr. and Mrs. Norris will reside at 313 South Eighteenth Street.

Scientific Society Meetings for the Week Ending April 1, 1905.—Monday, March 27th, Mineralogical and Geological Section, Academy of Natural Sciences. Tuesday, March 28th, Northwest Medical Society; Philadelphia Neurological Society.

Nurses' Home Dedicated.—A home for the nurses of the Woman's Hospital was dedicated with appropriate ceremonies on March 15th. Dr. Alice M. Seabrooke, superintendent of the Woman's Hospital, and Miss Margaret P. Saunders, president of the board of directors, received the guests.

Abortive Inquest by a Coroner's Jury.—A coroner's jury has found that Lillian G. Ware died of peritonitis in the Howard Hospital. The inquest failed to reveal who had removed certain of the internal organs after death and had thereby frustrated an autopsy by the coroner's physician.

Personal.—On March 11th, Mr. Henry S. Wellcome, of the firm of Burroughs, Wellcome, and Co., of London, England, who, with his wife, is making a visit to the United States, was tendered a reception at the Philadelphia College of Pharmacy. Mr. Wellcome presented a gold loving cup to the college in memory of his student days, he having graduated in the class of 1874.

Dr. and Mrs. Charles H. Frazier have issued invitations for receptions on March 18th and 25th to the faculty of the medical department of the University of Pennsylvania.

Report of the Kensington Hospital for Women.—The twenty-first annual report of the Kensington Hospital for Women has just been received. During the year 388 patients were treated in the wards, of whom 136 were cases for abdominal section. There were 446 other gynæcological operations performed. In the dispensaries 628

new patients were treated, who made a total of 3,003 visits, and of whom 70 were admitted to the wards. The hospital needs a department for the isolation of septic patients, with an operating room for such cases exclusively; a larger nurses' home; a high pressure steam sterilizing plant; and a modern steam laundry. The finances of the institution, according to the treasurer's report, show a deficit of about \$2,000.

Mount Sinai Hospital Dedicated.—On the afternoon of March 13th the Mount Sinai Hospital at 1407 to 1429 South Fifth Street was dedicated and opened to the public. There were exercises in the B'Nai Reuben Synagogue and an inspection of the new buildings. Dr. M. Y. Belber, Dr. L. Effron, Dr. A. Brav, Dr. B. L. Gordon, Dr. S. J. Gittelson, Dr. Edwin Rosenthal, Mrs. M. Y. Belber, Mrs. David Phillips, Mrs. Henry S. Belber, Mrs. L. Mark, Miss Jeanette Kabat, Miss Ida Sperling, and Mrs. L. Bernstein were of the reception committee.

Deaths.—Dr. A. B. Craig died at his home on March 13th of cerebrospinal meningitis, which he contracted from a patient on whom he had been in attendance. Dr. Craig, who was 33 years old, graduated from the Jefferson Medical College in 1893. He was an assistant demonstrator of surgery in the Jefferson Medical College, where it is proposed to erect a tablet to his memory.

Dr. W. W. Meyers died on March 11th at his home, 1940 North Twenty-first Street, aged 60 years. Dr. Meyers graduated from the Maryland University and Medical College. He was an assistant surgeon in the navy during the Civil War. For twelve years, up to six years ago, he was a medical inspector in the city of Philadelphia.

The Health of the City.—The following cases of transmissible diseases were reported to the bureau of health for the week ending March 11, 1905:

	Cases.	Deaths.
Malarial fever.....	1	0
Typhoid fever.....	178	12
Scarlet fever.....	38	1
Chickenpox.....	55	0
Diphtheria.....	56	11
Cerebrospinal meningitis.....	5	1
Measles.....	20	0
Whooping cough.....	11	3
Tuberculosis of the lungs.....	63	80
Pneumonia.....	92	82
Erysipelas.....	13	1

The total deaths for the week were 599 in an estimated population of 1,438,318, corresponding to an annual death rate of 21.66 per 1,000 population. The total infant mortality was 123; under one year, 102; between one and two years, 21. There were 45 still births; 23 males and 22 females. The following deaths from other transmissible diseases were reported: Tuberculosis, other than tuberculosis of the lungs, 7; dysentery, 3; diarrhœa and enteritis under two years, 11. The increase in the number of cases of typhoid fever, 178 cases this week (ending March 11th) as compared with 92 cases last week (ending March 4th), is attributed by the health authorities to a failure of the people to boil or to filter their drinking water. From the district receiving filtered water exclusively (twenty-first and twenty-second wards) there were 6 cases re-

ported, and from the district part of which receives filtered water (part of twenty-fourth and twenty-seventh wards), 12 cases were reported. It should be remembered that many of the inhabitants of these districts spend the day at work in districts in which filtered water is not supplied. The death of a physician from cerebrospinal meningitis, contracted from a patient, and the closure of a school from Friday night until Monday morning for fumigation, because one of the pupils was reported suffering from cerebrospinal meningitis, has given rise to a great deal of hysterical clamor in the newspapers, none of which is warranted. The weather bureau records show that the climatic conditions are moderating; the maximum temperature for the week was 49° on the 10th, the minimum was 16° on the 5th. The total rainfall was 1.62 inches.

Bureau of Health Statistics.—During February, 1905, the division of medical inspection of the bureau of health made 2,215 inspections, excluding those of schools. There were 25 cases submitted for special diagnosis. There were 4,950 visits made to schools and 823 children were excluded from school. Two hundred and fifty-five cultures were taken, 91 injections of antitoxine were given and 557 vaccinations were done. In the division of milk inspection 3,895 inspections were made of 89,791 quarts of milk, of which 45 quarts were condemned. One hundred and two chemical examinations and 671 microscopical examinations were made. In the division of disinfection 196 fumigations were made for scarlet fever, 252 for diphtheria, 74 for typhoid fever, 68 for tuberculosis, 82 for various other diseases, and 18 fumigations of schools were done. In the bacteriological laboratory 1,800 examinations were made for diphtheria, 330 examinations of blood for the serum diagnosis of typhoid fever, 688 examinations of milk, 104 of sputum, and 961 bottles of antitoxine were supplied. One hundred and forty-eight analyses were made in the chemical laboratory. The following are the statistics of the Municipal Hospital for February, 1905:

	Remain- ing.	Re- ceived.	Dis- charged.	Died.	Remain- ing.
Diphtheria	65	72	72	14	51
Scarlet fever.....	122	51	75	5	93
Smallpox	0	0	0	0	0
Other diseases.....	0	1	0	0	1

Henry Phipps Institute Report.—The first annual report of the Henry Phipps Institute for the study, treatment, and prevention of tuberculosis has been issued and one of its features was commented on in our editorial columns.¹ The report is a carefully prepared record of the work done by this institution and its excellent staff during its first year of activity. It shows that 2,039 cases were treated during the year, of which 254 were treated in the hospital wards. These cases are then classified according to nativity, age, social condition, occupation, source of contagion, etc., in a very thorough manner. A summary of the autopsies is made by Dr. Joseph Walsh; the laryngological work is described by Dr. George B. Wood; the neurological report by

Dr. D. J. McCarthy has been noted as indicated above; Dr. Mazzyck P. Ravenel describes an uncommon case of fibroid phthisis with marked bronchiectasis; Dr. H. R. M. Landis makes a report on the colored patients; and Dr. J. W. Irwin gives a valuable statistical study of tuberculosis in Philadelphia. The report also contains the popular lectures delivered during the year under the auspices of the institute by Dr. Edward L. Trudeau, Dr. William Osler, Dr. G. Sims Woodhead, Dr. Herrmann M. Biggs, and Dr. Eduardo Maragliano.

GENERAL.

Detroit Board of Health.—Dr. J. B. Kennedy has been elected president of the board of health of Detroit, to succeed S. T. Douglas; Dr. C. G. Jennings is the new vice-president.

The Erie County Medical Society, of Buffalo, has elected these officers: President, Dr. Arthur Bennett; vice-president, Dr. Grover Wende; secretary, Dr. David E. Wheeler; treasurer, Dr. Adolph H. Urban.

Gift to a Cleveland Dispensary.—Mr. John D. Rockefeller has given \$25,000 to the Women's and Children's Free Dispensary of Cleveland. The conditions have not yet been made public, but it is supposed that the institution is to raise a similar amount.

Bequests to Chicago Charities.—Among the bequests of the late John D. Murphy, of Chicago, were the following: St. Luke's Hospital, \$2,000; Alexian Brothers' Hospital, \$2,000; Mercy Hospital, \$2,000; Home for Destitute Crippled Children, \$500; Presbyterian Hospital, \$2,000.

Medical Society of the Missouri Valley.—A well attended meeting of this society was held at Kansas City, March 23rd and 24th. Twenty-nine papers were read and discussed. An enjoyable "smoker" was held at the Midland Hotel on the evening of March 23rd.

Dr. Osler's Successor.—Dr. William T. Councilman, of the Harvard Medical School, has been elected to succeed Dr. William Osler as professor of medicine at Johns Hopkins Medical School. Dr. Councilman graduated from the medical department of the University of Maryland. He has been professor of pathology at the Harvard Medical School since 1892.

Resignation of Dr. F. W. Draper.—Dr. F. W. Draper, for twenty-eight years medical examiner of Suffolk county, Mass., has tendered his resignation to Governor Douglas, to take effect June 30th, next, at which time his appointed term ends. Dr. Draper was appointed to the position at the time the office of medical examiner was created, and he holds an unimpeachable record during four terms of seven years each.

An Acknowledgment by Dr. Wieder and Dr. Springer.—We regret that our issue of March 18th went to press too early to allow the appearance of the following acknowledgment, which should have formed the concluding paragraph of the communication on Tuberculous Meningitis

¹ New York Medical Journal and Philadelphia Medical Journal, March 4, 1905, p. 447.

and Stricture of the Rectum, by Dr. Wieder, of Philadelphia, and Dr. Springer, of Wilmington, Del. In conclusion the writers wished to express their gratitude to Dr. Roland G. Curtin and Dr. William E. Hughes, in whose ward the case occurred, for permission to publish the same, and to Dr. J. Dutton Steele for his valuable assistance in the preparation of the pathological report. Dr. Wieder and Dr. Springer wish also to express their gratitude to Dr. Striker for permission to report the case of Uraemia and Pericarditis in our issue of March 4, 1905, and to Dr. J. Dutton Steele for his valuable assistance in preparing the pathological report of the same case. This acknowledgment was inadvertently omitted at the time of publication.

The Optometry Bill at Albany.—The Rosenstein bill, which seeks to regulate the practice of optometry in this State, was opposed before the assembly committee on public health on March 15th by a delegation representing the New York State Medical Society, headed by Dr. Frank Van Fleet, of New York, and composed of Dr. M. L. Foster, Dr. Alexander Shaw, Dr. Theodore Mundorff, and Dr. J. R. Schwinzer, of New York, and Deputy Health Officer Edward Clark, of Buffalo. The main contention against the bill was that a man should not be licensed by the State to care for the eyes unless he understood the practice of medicine and was familiar with anatomy. The bill was favored by B. B. Clark, president of the State Optical Society; W. W. Bissell, E. E. Arrington, of Rochester; A. T. Kenney, of Utica; S. Stern, of Kingston; and A. J. Cross, and Alexander Martin, of New York. They contended that the enactment of the bill into a law would preserve the public health, as it would stop inexperienced persons from caring for the eyes. At present they claimed that there is no law to stop peddlers or any persons from fitting eyeglasses, no matter how incompetent they may be.

Special Trains to the Next Meeting of the American Medical Association.—Arrangements have been completed under which the Northern Pacific Railway will run three solid special trains through to the Pacific Coast for physicians who go West early in July to attend the coming sessions of the American Medical Association. The first special will run through from Chicago, leaving June 30th and reaching St. Paul July 1st, proceeding West and stopping at Gardiner, Mont., for a five and a half day tour of the Yellowstone National Park. A second solid special train will leave Chicago July 1st, reaching St. Paul July 2nd, and proceeding West to Gardiner for a similar tour of the Yellowstone. A third special train will leave Chicago July 6th, running through to Portland, with stops at several important points. The Northern Pacific has been designated as the official route for physicians, and the National officers will go West on one of the first two specials, in both of which accommodations are nearly all taken up. Arrangements are now being made by numerous small parties for space in the third special, and it is possible that additional trains will be arranged for if the demand for reservations continues. Each special

will be made up of standard Pullman equipment, with through dining cars and ample baggage accommodations. Every facility which adds to luxurious comfort *en route* is being arranged for, and the train schedules have been worked out with especial reference to the convenience of the travelers. The third special will arrive in Portland the morning before the convention opens. Berth reservations should be made through C. A. Matthews, General Agent Passenger Department, N. P. R., Chicago. Service can best be afforded if physicians will cooperate in this matter, arranging their plans accordingly.

Statement of Mortality in Chicago for the Week Ending March 18, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's estimated midyear populations of 1,990,750 for 1905 and of 1,932,315 for 1904:

	Mar. 18, 1905.	Mar. 11, 1905.	Mar. 19, 1904.
Annual death rate per 1,000.....	14.57	16.41	15.02
Total deaths, all causes.....	557	627	578
By sexes—			
Males.....	324	364	338
Females.....	233	263	240
By ages—			
Under 1 year.....	133	135	103
Between 1 and 5 years.....	51	70	35
Over 60 years.....	98	112	122
Important causes of death—			
Acute intestinal diseases.....	27	28	14
Apoplexy.....	15	13	24
Bright's disease.....	34	38	24
Bronchitis.....	31	30	22
Consumption.....	63	82	74
Cancer.....	22	19	20
Convulsions.....	14	19	19
Diphtheria.....	11	2	10
Heart diseases.....	42	45	32
Influenza.....	8	10	2
Meningitis.....	17	22	28
Nervous diseases.....	17	22	2
Pneumonia.....	103	138	137
Scarlet fever.....	2	1	5
Smallpox.....	3	8	..
Suicide.....	11	8	7
Typhoid fever.....	4	8	7
Violence (other than suicide).....	29	25	26
Whooping cough.....	11	6	2
All other causes.....	108	117	123

A very gratifying decrease of the total number of deaths and of the death rate is noted. The total 557 deaths is seventy fewer than for the previous week and the rate is 14.57 per cent. less. The principal reductions are in consumption—nineteen fewer—and in pneumonia—thirty-five fewer. A wholly unanticipated increase of deaths from diphtheria occurred—eleven, as compared with only two the previous week. There had been no forewarning of this, the laboratory examinations during the previous fortnight showing a marked reduction in the findings of the diphtheria bacillus. Nor was there any common source of infection; on the contrary, the cases were widely distributed over the city. The obvious explanation is that, by some sinister coincidence, the diphtheria antitoxine was not administered in the early stage of the disease or not in sufficient quantity. No child dies of diphtheria to whom 3,000 units of antitoxine are administered within the first forty-eight hours of the attack—repeated, of course, if necessary. And when in doubt as to the nature of a "sore throat," don't hesitate. Give the child the benefit of the doubt—and give it antitoxine at once. If not diphtheria, no possible harm can result. If diphtheria, a life will be saved.

LYON MEDICAL.

February 5, 1905.

1. Cystic Peritonitis with Compression of the Common Bile Duct, By MOUISSET and VALLAS.
2. Mutism Lasting Sixteen Months in a Degenerate Tramp. Cure by Suggestion, By LANNOIS and FEUILLADE.

1. **Cystic Peritonitis With Compression of the Common Bile Duct.**—Mouisset and Vallas describe a case of localized peritonitis which involved the fold of omentum at the level of the bile ducts, called in the French textbooks *l'arrière-cavité des épiploons*, which compressed the common bile duct. The condition was relieved by operation. Unfortunately a fistula from the duodenum resulted.

2. **Mutism Cured by Suggestion.**—Lannois and Feuillade report the case of a man, 26 years of age. His history is followed from birth. He had a remarkable memory for insignificant facts, such as dates, not only of important events, but of the birthdays of the various inhabitants of his native village, the paging of a book, and the exact contents of each page, and had a vagabond spirit which caused him to roam as a tramp. In 1900 he began to stammer. The stammering became worse until in June, 1903, he lost the power of speech. In November, 1904, speech was restored by means of suggestion.

February 12, 1905.

1. The Social Struggle Versus Tuberculosis, By JULES COURMONT.
2. Intravesical Separation and Ureteral Catheterization, By Dr. RAFIN.

1. **Social Struggle Versus Tuberculosis.**—Courmont's argument is that social conditions are largely responsible for tuberculosis, by the crowding together in unsanitary surroundings people who have not been successful in the social struggle. As remedies he considers disinfection of the sputum and sterilization of milk as of great importance, but a reduction of poverty, misery, and alcoholism, with hygienic improvement to be necessary to control the disease.

2. **Intravesical Separation and Ureteral Catheterization.**—Rafin presents the relative merits of these two methods of obtaining the urine from each kidney for examination chemically, microscopically, and bacteriologically. The two methods are compared from various standpoints, the dangers and difficulties are considered and the conclusion is finally reached that neither one is perfect. Intravesical separation, with Luys's instrument, is preferred by those who are unable to overcome the difficulties presented by cystoscopy and ureteral catheterization, as well as by those who dread renal contamination, but the catheterization is preferred by those who are skilled in its performance.

February 19, 1905.

Temporal Abscess of Otitic Origin; Trepanation; Recovery; Clinical and Therapeutical Considerations, By EUGENE VILLARD and LECLERC.

Otitic Brain Abscess.—Villard and Leclerc describe a case of otitic brain abscess. The patient was brought in in a state of coma and exhibited no symptoms of localization. The mastoid was opened at the level of the antrum, the lateral sinus exposed and found normal. The cerebellar fossa was also normal. Finally the bone was trephined 3 cm. above the external auditory meatus and an abscess found situated deeply in the temporal lobe. Recovery was prompt. Six months after the operation the patient's intellect was clear and he complained only of occasional headache and vertigo, the attacks of which were growing less marked.

February 26, 1905.

1. The Antituberculosis Dispensary, By JULES COURMONT.
2. Complementary Note on the Action of Formic Acid on the Muscular System, By E. CLÉMENT.

1. **The Antituberculosis Dispensary.**—Courmont in this article, which is supplementary to the one published last week on the social struggle versus tuberculosis, presents a description of a dispensary of the Calmette type at Lyons, of the division of the patients into contagious and non-contagious, of the establishment of a sanitary barrier about contagious tuberculous cases, and of the routine of management.

2. **The Action of Formic Acid on the Muscular System.**—Clément says that formic acid increases the muscular force and activity, as well as the power of resistance to fatigue, and presents the experimental results from which he has deduced the statement. Acting on the vesical muscle it facilitates micturition and increases the force on emission. It exercises a very favorable effect of diuresis, particularly in combination with alkalies. It increases the tonicity and contractility of the muscles of the larynx. Beneficial effects were observed in three cases of arteriosclerosis with albuminuria. It increases arterial tension when low by its action on the cardiac muscle, but decreases it when high from trouble with the peripheral circulation by its action on the muscular fibres of the arteries. The dose for an adult is 2 to 3 grammes, according to the height and weight of the person. Sodium formate may be used in rather larger doses.

PRESSE MEDICALE.

February 18, 1905.

Syphilis of the Stomach, By GEORGES HAYEM.

Stomachal Syphilis.—Hayem reports several cases in which symptoms of various gastric conditions were counterfeited. The clinical histories, symptoms, and the results of examinations of the contents of the stomach after the ingestion of a test meal are given. His conclusions are that the stomach is not rarely the seat of tertiary syphilis, which can produce serious clinical manifestations and simulate many definite types of stomach diseases. The first type given is that of ulceration with hæmatemesis, symptomatically resembling ulcer of the stomach. The second type is one of benign stenosis of indeterminate cause, without tumor, resembling a stenosis of ex-

trinsic origin. The third is a pyloric or prepyloric tumor, suggestive of the development of a cancer of the pylorus. The fourth simulates a cancerous stenosis. Our knowledge of these conditions is incomplete. The diagnosis is invaluable when it can be made. Analysis of the gastric juice furnishes an important indication, because although its constituents closely resemble those in cases of cancer a difference is found in the absence of the lactic reaction, though it may be objected that this reaction is not absolutely constant in cases of cancer. For treatment he recommends hypodermic injections and washing out of the stomach with a solution of potassium iodide. In cases of stenosis of obscure origin it is wise to try specific treatment first unless the demand for operative relief is urgent.

The Conduct of a Case of Foreign Body in the Œsophagus of an Infant,

By L. BERARD and R. LERICHE.

Foreign Body in the Œsophagus of an Infant.—Berard and Leriche say that radiography should be practised whenever possible to locate accurately the position of the foreign body. Then there are three things which may be done; it may be removed through the mouth, be removed by œsophagotomy, or be pushed down into the stomach. The latter is not a good procedure as it risks not only lacerations of the mucous membrane, but also that the attempt may cause impaction and complete obstruction lower down at a point less accessible by operation. With the aid of the œsophagoscope extraction through the mouth can sometimes be safely practised, but without the aid of this instrument the operation is not safe. External œsophagotomy is usually the preferable procedure. It is a simple operation, more easily performed on a child than on an adult, and less dangerous than has been thought. In all cases the passage of a œsophageal sound is useless and is apt to be dangerous.

By GIULIO TAROZZI.

3. Parkinson's Disease. Postinfective and Family Paralysis Agitans,

By PAPINIO PENNATO.

3. Parkinson's Disease.—Pennato reports two cases of paralysis agitans which developed in two very young members of the same family, both of whom had recovered from typhoid fever shortly

before the onset of the nervous affection. While the infectious character of Parkinson's disease cannot be affirmed with certainty, yet it is unquestionable that it follows infectious maladies, especially dysentery and typhoid fever. Parkinson's disease rarely occurs as a family affection, and for this reason the present cases offer a special interest. Bury reported two cases, while Borgherini reported three cases in one family and Gowers also saw two members of the same family affected. The patient, whose history is given in full, fell ill with typhoid fever at the age of twelve years, and during convalescence began to show the characteristic tremors and the tendency to fall backward. The symptoms grew worse until she was admitted to the hospital at the age of thirty-six years. Her brother was affected in the same way after typhoid fever, also at the age of twelve years. She died of the results of a mitral stenosis which had developed in the meantime. A study of the lesions found convinced the author that the pathological basis of paralysis agitans is not a diffuse senile change in the nervous system. It is in these cases occurring in comparatively young subjects that the theory as to the senile character of these changes in Parkinson's disease can be studied with profit. The lesions found in this case in brain, spinal cord, and peripheral nerves seemed to have been the result of an excessive use of all the organs and tissues of the body for a considerable time. In the absence of vascular changes, however, the case does not confirm the theory that the changes are due to precocious senility.

February 18, 1905.

1. Hemiplegia in a Case of Pneumonia (*To be continued*),
By CARLO FEDELI.

2. Effects of Removal of the Pancreas,
By TORINDO SILVESTRI.

3. Surgical Intervention in Cirrhosis of the Liver with Ascites (*Part II*),
By ORESTE CIGNOZZI.

4. The Biology of Some Anaerobic Germs, and an Easy Method of Cultivating Them (*Part II*),
By GIULIO TAROZZI.

2. Effects of Removing Pancreas.—Silvestri found as the result of experiments on dogs, that the constant effects of removing the pancreas consisted of a transient glycosuria, occurring within twenty-four or thirty-six hours after the operation, and followed afterwards by a slight glycosuria which lasted from forty to sixty days. There were also disturbances of digestion and nutrition, emaciation, polyuria, excessive and abnormal appetite, and thirst. These disturbances were not fatally progressive, but disappeared after a time. The results seem to show that the pancreas has an influence on the metabolism, regulating the processes thereof in some way. This is proved by the fact that injections of the extract of pancreas in these dogs proved of benefit to the general metabolism, but did not have any effects on the glycosuria. The removal of the spleen and of other organs acts in the same way, although less markedly. The results obtained by various observers with animals with removed pancreas vary greatly, and this is the principal difficulty in solving the question as to the action of the pancreas. These differences in

results, the author thinks, are due to the individual predisposition of the animals, as one author has produced glycosuria of various types by experimentally inducing neuritis in the peripheral end of the cut vagus. The differences in results also depend, in a measure, on the ages of the animals used, and also on the presence of various complications, due to the operation, etc. The results which he obtained correspond closely to the symptoms seen in man in severe forms of diabetes. He pleads for a broader interpretation of the term diabetes, and asks that glycosuria should no longer be held synonymous with that disease. The worst clinical forms of diabetes sometimes are accompanied by very little sugar, and the lightest cases show sometimes the largest amounts. He considers diabetes as a disease of autolysis, in which the decomposition of the proteid molecule goes on too fast, in which there is, so to speak, a gangrene of the organism. The bulimia and the polyphagia are only results of this abnormal decomposition.

GAZZETTA DEGLI OSPEDALI E DELLE CLINICHE

February 5, 1905.

1. A Case of Peripheral Paralysis of the Peroneal Nerve due to Measles, By G. B. ALLARIA.
2. How Does Tubercle Develop Under the Direct Influence of Specific Antituberculous Serum? By GIOVANNI GHEDINI.
3. Abnormal Development of the Clitoris, By VIRGILIO MAGGIONI.
4. Two Cases of Atrophy of the Optic Nerve as the Result of Injuries to the Head, By AGOSTINO CARBONE.

1. Peripheral Paralysis of Peroneal Nerve due to Measles.—Allaria reports a case of measles which was followed by paralysis of the peroneal nerve, and which he deemed to be of peripheral origin. The patient was a girl, aged nine years, who began to complain of pain in one foot, "which felt as though she wore a tight shoe" during an attack of measles. After the eruption had disappeared and she was again allowed to walk, it was noted that she dragged that foot. The leg muscles were atrophied and on the affected (left) side, the cutaneous sensibility was diminished and the skin reflexes were abolished. The patient slowly recovered under the use of massage, electricity, etc.

2. Action of Direct Application of Antituberculous Serum on Tubercle.—Ghedini injected virulent cultures of tubercle bacilli into the joints of a number of rabbits. Some of these animals were left untreated, and developed typical and severe tuberculous synovitis and arthritis. Another series received subcutaneous injections of antituberculous serum (Maragliano's) into the skin of the back, while still another set received these injections directly into the joints. In the second group, the rabbits which received subcutaneous serum injections, the reaction to the tuberculous infection was very much diminished, while in the animals which received the antituberculous substance directly into the affected joints the reaction was still more feeble. Ghedini thinks that the direct injections were more effective because the antituberculous substance did not become diluted with blood plasma, nor did it need to travel a long distance before it reached the affected

spot. The practical application of these researches would be in the injection of antituberculous serum into tuberculous joints, or into tuberculous testicles. These injections would have to be given in doses of from two to five c.c. at intervals of two or three days for two or three months.

3. Anomaly of Clitoris.—Maggioni's case of anomalous clitoris occurred in a subject, twenty years old, who presented all the secondary sexual traits of a woman, and who showed regular labia majora and minora. In place of the clitoris there was, however, a large erectile organ which resembled a penis in every respect, except that the meatus urinarius was situated in the vestibule beneath the root of the enlarged clitoris. The enlargement of the organ began when the patient was twelve years old. She began to menstruate at eighteen and the little finger introduced into the vagina could make out the presence of an os uteri. The author cautions against mistaking such cases of enlarged clitoris for hermaphroditism.

February 12, 1905.

1. Diplococcemia with Multiple Secondary Localizations, By ALFREDO ROSSI.
2. A New Method of Serum Diagnosis in Tuberculosis, By E. MARZAGALLI.
3. Experimental Diplococcic Meningitis Due to Inhalation, By V. MARAGLIANO.
4. Contribution to the Study of Intestinal Occlusion Due to the Diverticulum of Meckel, By A. D. MONTINI.
5. Acute Circumscribed Edema in Malaria, By FERRUCCIO BINDI.
6. Acute Mastoiditis with Intracranial Complications of Otitic Origin, By D. PAPI.

1. Diplococcemia.—Rossi's patient was admitted with the signs of acute articular rheumatism. The sensorium was markedly depressed, there were no sweats, and the joint lesions appeared when the disease had already reached a considerable height. On the fourth day after admission, the ninth of the disease, the patient developed a pneumonic focus, which behaved in the regular way. When resolution set in an exudative pericarditis came on. There was also a diastolic-presystolic murmur at the mitral valve and a systolic murmur over the aorta transmitted upward. Bacteriological examination showed the presence of a diplococcus in the blood. The diplococcus of Fraenkel rarely localizes in the aorta as it did in this case. The patient recovered.

2. Serum Diagnosis in Tuberculosis.—Marzagalli gives the details of an interesting new method of serum diagnosis which he has used in tuberculosis. The preparation of homogeneous cultures of the germ is difficult, although Arloing and Courmont and others have succeeded. An easier method which the author proposes is to make an extract or pulp from the protoplasm of virulent and living tubercle bacilli by washing the germs in cold water, so as to remove all traces of culture media, and then triturating them with distilled water and filtering the triturate in Chamberland's filter. The resulting extract is an opalescent alkaline fluid, which is precipitated on the addition of the serum of tuberculous patients.

In order to make the diagnostic test, it is necessary to have tubes of this "pulp" in various dilutions, and to add a varying amount of the serum of the patient or animal experimented upon. If the result is positive, a precipitate will appear within four hours in a dilution of one part in five. The dilutions used should be that just mentioned, also 1:10, or 1:15, etc. The serum may also be poured into a very small test tube, and a little of the pulp fluid may be poured down the sides of the tube. A ring of precipitate will show a positive result at the point of contact of the two liquids. The various exudates may be used for diagnosis, but it is better to use pure blood serum. The method is much easier than that of Arloing and Courmont (with homogeneous cultures which agglutinate). The germ pulp can be kept for some time without deteriorating.

ROUSSKY VRATCH.

January 29, 1905.

1. On Chronic Diphtheria or Diphtheroid of the Larynx,
By A. D. PAVLOVSKI.
2. The Alleged and the Actual Incapacity for Reading,
By R. A. KATZ.
3. The Hedonal-Chloroform Method of Anæsthesia,
By A. G. ZALOGI.
4. A Case of Acute Dermatomyositis,
By M. A. GOLDENBLUM.
5. The Treatment of Scabies with Eudermol,
By V. F. DEMITCH.

1. **Chronic Diphtheria or Diphtheroid.**—Pavlovski discusses the subject of the atypical forms of diphtheria, which are characterized by chronicity, by the absence of the regular diphtheritic lesions, and are recognized as diphtheria only by the presence of the diphtheria bacillus in virulent form. Escherich gave the name *diphtheroid* to these cases. Recent researches have revealed a whole group of diphtheritic affections which have nothing in common with ordinary diphtheria clinically, and which when they attack the larynx are often accompanied by a dry atrophic state of that organ, with chronic hoarseness, or with attacks of croup without membrane. The same class of processes due to the diphtheria bacillus have also been recognized in certain forms of chronic fibrinous rhinitis and of atrophic rhinitis, as well as in some types of chronic fibrinous conjunctivitis. The author suggests that the term *diphtheromycosis* be applied to all the affections produced by the diphtheria bacillus, taken as a group. He reports a number of cases of chronic diphtheria of both the tonsils and the larynx. In one case of what appeared to be a follicular amygdalitis clinically, diphtheria bacilli were found, and remained for two weeks. A relapse of the disease occurred afterward, and the bacilli remained for three weeks longer. In another case there was acute amygdalitis and pharyngitis without membrane. Diphtheria bacilli were found, and antitoxine produced favorable effects. Death, however, occurred on the sixteenth day from paralysis of the heart. A third case was one of typical chronic diphtheria of the larynx with very slight atrophic changes, and no membrane. In this case diphtheria bacilli were found and persisted for a long time.

2. **Real and Imaginary Alexia.**—Katz studies two cases observed among public school children, in both of which there was said to be alexia. He finds that, besides the real inability to read on account of congenital word blindness, there is a pseudoalexia, due to astigmatism and other congenital visual defects. This was the case in a boy who came under his observation and in whom the proper glasses corrected the alleged alexia. Visual defects which give an apparent alexia in children may be due to irregularities in the development of the eye as the result of hereditary syphilis. Real alexia may be divided into the severe form in which the child is letter blind, and the milder form, in which the child is only blind to words. In these children visual memory for letters is developed rapidly, but the child has difficulty in remembering word images. In the severe cases the memory for figures is also affected, as a rule, while in the mild forms the child can memorize figures. Reading, however, cannot go on smoothly, because words are remembered according to the auditory memory or the motor-sensory memory of speech, or the motor memory of writing and not the visual memory. Mild forms of alexia are apt to be confounded with astigmatism or other visual defects which are characterized by extreme slowness and frequent mistakes in reading, as well as by severe and constant headaches. A diagnosis between real and false alexia is of great importance and should be made early, inasmuch as the false type which is due to visual abnormalities can be speedily corrected by glasses, while the real variety, due to cerebral maldevelopment, requires a course of prolonged special teaching and training. The severe cases of alexia are incurable.

4. **Acute Dermatomyositis.**—Goldenblum describes a case of dermatomyositis—that peculiar affection of the skin and muscles which was first classified as a separate disease by Unverricht. An interesting feature of the case reported was the fact that bacteriological examination revealed the presence of streptococci in the muscular tissues of the patient. These germs have been found also in the muscles in other cases of dermatomyositis, and have been connected with the infectious ætiology of the disease. Clinically, dermatomyositis is characterized sometimes by a short sudden rise of temperature, with general malaise, prostration, and weakness, headaches, and sweating. A few days later the pains in the muscles supervene. Sometimes the disease sets in with these pains without any preliminary symptoms. The muscular pains increase in severity until they become well nigh unbearable, and the patient does not dare move or allow any one to touch him. Any muscle may be affected, and the only one thus far known to have escaped is that of the bladder. The respiratory and deglutition muscles are often severely involved and at times the affection may prove fatal. Of fifteen cases, eleven ended in the death of the patient. The prognosis of the disease is very grave. Catarrhal angina often accompanies the disease and sometimes there is nephritis. In the case reported the patient was a man twenty-two years old, with a negative history, except that he had had a previous attack nine years before. The disease began with a maculopapular eruption; later on during the disease, œdema ap-

peared at various points. The patient died of exhaustion and of inanition owing to the involvement of the pharyngeal and respiratory muscles. He never lost consciousness. The author regards this case as one of streptococcus infection, with the tonsils or pharynx as probable portals of entry.

1. On the Surgical Treatment of Diseases of the Bile Ducts (*To be continued*), By M. M. KOZNETSOFF.
2. The Characteristics of Bullet Wounds in the Present War, By N. K. CHOLINE.
3. A Case of Acute Articular Rheumatism in a Nursing Infant, By V. V. SHENGELIDZE.
4. Case of Penetrating Wound of the Abdomen, with Prolapse of the Injured Intestine; Case of Compound Fracture of the Skull with Injury to the Brain, By J. G. DILLON.

2. Character of Bullet Wounds in Russo-Japanese War.—Choline finds from a study of gunshot injuries in the present war, that the Japanese bullet fulfils sufficiently well the requirements of humanity, for the absence of contusion and fragmentation in its track renders the treatment of wounds received by the Russians easy and simple. The wounds as a rule heal rapidly without complications. The majority of the soldiers who received wounds of the skull, the chest, the abdomen, or the spine, required more or less protracted treatment at some place close to the battlefield. He recommends the establishment of as many hospitals as possible close to the battlefield so as to avoid if possible the tedious and dangerous transportation of the wounded. The possibility of late complications, in his opinion, requires that the patients be kept in the hospital for a long time, so as to give the wounds a good opportunity to heal. The present conditions of transporting the wounded are highly unsatisfactory and even fatal to the wounded, and this matter requires immediate and rational correction. Some details in this paper may be interesting to American surgeons: The author begins by saying that the Russian surgeons had been unacquainted with the effects of small calibre rifle bullets before the present war. He himself had charge of 230 wounded at the Hospital of the Nobles in Harbin. Most of the wounded arrived there five or six days after the battle in which they were wounded, so that his experience with fresh wounds was limited. The Japanese bullets have the greatest initial velocity yet attained by any rifle projectile, i. e., 750 metres a second. The worst wounds produced are those made within a distance of from one to five hundred metres. Beyond five hundred metres the wounds are all clean and heal easily. The range is two thousand metres. The bullet is 6.5 mm. in diameter and weighs 10.5 grammes, while the Russian bullet is 7.6 mm. in diameter and weighs 13.7 grammes. The great peculiarity of the Japanese bullets is their straight course and their penetrating power. No tissue of the body deflects them, and they pass through interposed objects, such as thick books in wooden bindings. Their calibre is so small that the opening of entrance is indistinguishable from that of exit. Sepsis was rarely noted in these cases, as no fragments of clothing were

carried in by the swift passage of the projectile. Sepsis was noted usually only in those soldiers who had been probed and examined at the first aid station in the field. The author warns against all such probing as unnecessary and dangerous. The Japanese bullets have a special tendency to wound blood vessels and nerve trunks. Bones suffer comparatively clean penetration. Wounds of the joints healed with remarkable smoothness, and but rarely was an operation required.

3. Acute Rheumatism in an Infant.—Shengeldize describes a case of articular rheumatism of the acute type in an infant aged about two weeks. The mother suffered from the same trouble while nursing this little girl. The infant had the typical swelling, redness, pain, etc., at the ankle, and at one of the interphalangeal joints, fever, etc. The author found but a few similar cases in literature. He thinks that rheumatism may be transmitted by the mother to a nursing infant. Schaefer believes that the disease may be transmitted through the placenta. It is remarkable that heart complications have thus far not been observed in infants with acute rheumatism, but it is possible that they develop later when these infants are no longer under observation. A noteworthy feature in the case reported was an exudate in one of the maxillary articulations.

4. Two Successful Operations.—Dillon's cases (wound of the abdomen and fracture of the skull) are only remarkable because the operations were performed in a hospital at Vilna, where there is no operating room, and it is almost impossible to sterilize anything. The room in which this surgeon operates is used also as a dispensary, an office, and a drug shop.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

March 18, 1905.

1. Clinical Examination of the Urine. A Critical Study of the Commoner Methods (*To be continued*), By RICHARD C. CABOT.
2. Models for Teaching the Anatomy and Operative Treatment of Inguinal Hernia, By DANIEL N. EISENDRATH.
3. A System for the Surgical Correction of Hare Lip and Cleft Palate, By GEORGE V. I. BROWN.

8. The Blood in Lobar Pneumonia, with Remarks Concerning Treatment, By EDWARD C. ROSENOW.
9. Immunity. Chapter VIII (*Continued*).

2. Models for Teaching Surgery.—Eisendrath illustrates and describes a set of models he has devised for facilitating the teaching of the

operative treatment of inguinal hernia. Two kinds of model are recommended: (1) A frame on which are stretched in succession various layers of different colored sweater cloth and muslin. Each of the layers corresponds to a definite component of the abdominal wall. By properly cutting and sewing together the various pieces of cloth an artificial inguinal canal is formed, through which a cord and a sac are thrust. The various steps of any operation can now be easily demonstrated. (2) In the second model a box without ends and with slatted sides is used in place of the frame. The pieces of cloth are stretched on the slats. With this model it is possible to view the structures represented from all sides.

3. **Hare Lip and Cleft Palate.**—Brown advocates the adoption of a more or less formal system for the treatment of hare lip and cleft palate. In his present paper he barely touches on the technics of operation. He occupies himself chiefly with a discussion of the general principles which should be observed in order to obtain good results. He claims originality for the following methods: (1) The reduction in the width of the palatal fissure by means of an appliance which is fastened to teeth on opposite sides of the jaw and which is furnished with a screw which when tightened narrows the palatal cleft. (2) A form of preparatory treatment for infants suffering from lip deformities which tends to overcome the deformity before operation is resorted to. (3) Various minor operative procedures. The article is illustrated, but several of the illustrations referred to in the text are missing.

5. See this *Journal*, Vol. LXXX, page 232.

8. **The Blood in Pneumonia.**—Rosenow asserts: (1) That the pneumococcus can be isolated from the blood of pneumonia patients in about ninety per cent. of all cases. (2) That pneumococci in the blood may be demonstrated, not infrequently, before the advent of typical physical signs. They tend to disappear at or about the crisis and are usually absent after it. (3) Other things being equal, a high leucocyte count is a favorable sign. (4) It seems probable that the pneumococcus, by its growth in the consolidated lung and in the blood of the patient during life, produces acids as it does in the test tube, and that some of the symptoms of pneumonia are due to this acid intoxication. If this is a fact it would probably be well to follow the practice that has recently been adopted by Billings of giving pneumonia patients large and repeated doses of sodium bicarbonate.

Abuse of Medical Charity.

- (a) Medical Charity, By GEORGE W. GAY.
- (b) Some Abuses of Medical Charity, By HASKET DERBY.
- (c) Abuse of Medical Charity in Boston, By J. W. ELLIOT.
- (d) The Private and Public Hospital, By ALFRED WORCESTER.
- (e) The Regulation of Medical Charity, By FARRAR COBB.

- (f) A Possible Remedy, By JOHN C. MUNRO.
- (g) Medical Charity at the Massachusetts General Hospital, By FREDERIC A. WASHBURN, JR.
- (h) The Physician and the Hospital Private Patient, By E. W. CUSHING.
- (i) Certain Faults in Medical Charities, By SAMUEL CROWELL.
- (j) Abuse of Medical Charity in the Suburban Districts, By CHARLES H. COOK.

The Abuse of Medical Charity.—The ten papers on various aspects of medical charity were read at a joint meeting of the Medical Library and the Suffolk District Branch of the Massachusetts Medical Society. The papers do not concern themselves so much with medical charity in the abstract as they do with the alleged abuses encouraged by some of the Boston hospitals. The chief grievance seems to be against the Massachusetts General Hospital. This hospital has a certain number of rooms, ranging in price from twenty to thirty-five dollars per week, to which private patients are admitted. They are attended free of charge by the regular staff and under no circumstances is the attending physician allowed to make any charges for either medical or surgical services rendered. The papers will be chiefly of interest to Bostonians, as it is stated that one half the population of their native city has been pauperized medically, while in New York and Philadelphia only one quarter of the population gets medical service free.

MEDICAL RECORD.

March 18, 1905.

1. Results of Fifteen Hundred Operations for the Radical Cure of Hernia in Children, Performed at the Hospital for Ruptured and Crippled Between 1891 and 1904, By WILLIAM T. BULL and WILLIAM B. COLEY.
 2. Acne and Its Treatment, By GEORGE T. JACKSON.
 3. The Limitations of the Value of Nitroglycerin as a Therapeutic Agent, By H. P. LOOMIS.
 4. Psychological Aids; or the Practical Use of Well Known Laws of the Mind, By EUGENE COLEMAN SAVIDGE.
 5. Report of a Case of Vaginal Cesarean Section with Recovery, By SIMON STRAUSS.
1. **Hernia.**—Bull and Coley give a very complete analysis of the 1,500 cases they have operated in from December, 1891, to October, 1904. We can only give a few statistics. All the operations reported, with the exception of 20, were performed on children under fourteen years of age. Only one tenth of the children under treatment for hernia were subjected to operation. The mortality was three tenths of one per cent. There were six relapses after 1,076 Bassini operations, and five relapses after 125 operations in which the cord was not transplanted.
2. **Acne.**—Jackson believes that it is probable that acne is due to a parasitic infection of the skin. In order that the disease get a foothold it is necessary for the soil (the skin) to offer a favorable habitat for the offending organism. If these views are accepted the indications for treat-

ment are: (1) Improve the condition of the skin, so that it will no longer be a suitable culture ground for the bacillus. (2) Empty the follicles of the skin of the colonies of bacilli. (3) Keep the skin constantly aseptic, so that any bacilli that escape on it will be killed, and no new infection of the skin will be possible. The author meets these indications as follows: (1) Constitutional treatment and regulation of the diet with a view to placing the patient in as perfect a state of general health as possible. (2) Mechanical cleansing of the skin by means of the curette, the acne lancet, and the comedo expressor. (3) Chemical disinfection of the skin. The drugs that are of greatest service in acne are sulphur, resorcin, mercury, and salicylic acid. Lotions are better than ointments, and the old fashioned *lotio alba* is often of the greatest value. The author has not as yet met in private practice a case of acne which he would have been willing to treat by means of the x ray.

3. **Nitroglycerin.**—Loomis, as the result of clinical and laboratory observations, reaches the following conclusions regarding the therapeutic value of nitroglycerin: (1) The usual dose of nitroglycerin ($\frac{1}{100}$ grain) is too small to produce any effect in pathological conditions; $\frac{1}{50}$ grain is a minimum dose. (2) It is a perfectly safe drug to use. Even in the large and repeated doses used he has never seen any ill effects. (3) High arterial pressure in man is not perceptibly affected by it, nor is dilatation of the blood vessels apparent. (4) Its effects are very transient as shown by the experiments on dogs, and the ordinary dose of $\frac{1}{100}$ grain every four hours could not possibly have any effect on the arteries. (5) Nitroglycerin is said to increase the quantity of urine in chronic Bright's disease, but after keeping accurate records of the daily amount of urine passed, he was never able to satisfy himself that any increase seen was due to this drug. (6) He believes that in conditions due to arterial spasm so called, such as angina pectoris, migraine, and asthma, nitroglycerin may be of benefit, in full doses often repeated, but not in arterial sclerosis where the arteries themselves are more or less changed. For relaxing the arteries and reducing the blood pressure in arterial sclerosis there is nothing equal to five grains of chloral given every four hours.

MEDICAL NEWS.

March 18, 1905.

1. The Fresh Air Treatment of Surgical Tuberculosis,
By LINSLEY R. WILLIAMS.
2. Aural Affections in Children; Necessity of Their Early
Recognition by the Family Practitioner,
By HERMAN JARECKY.
3. The Widal Test for Practising Physicians,
By JOHN H. BORDEN.
4. The Technic of Perineal Prostatectomy,
By GEORGE RYERSON FOWLER.
5. Superficial Inguinal Hernia, with Report of a Case,
By ALBERT E. SELLENINGS.
6. The Importance of the Physical Examination of the
Back in General Diagnosis, By JOHN P. ARNOLD.

7. Local Anæsthesia, by Cataphoresis and by Mechanical
Pressure,
By WILLIAM JAMES MORTON.

1. **Surgical Tuberculosis.**—Williams reviews the work that has been done abroad, specially in France, to test the value of the seaside open air treatment of surgical tuberculosis. The reports from Europe are very encouraging. In the summer and winter of 1904 similar experiments were conducted at Coney Island. The author tells in detail the history of this American experiment. With regard to results, it may be said, in a general way, that they were satisfactory. The author holds that it has been proved that constant fresh air and good food, with the aid of orthopaedic and conservative surgical treatment, is the only way of treating surgical tuberculosis. He believes, but cannot prove, that sea air is the best air. The cost, including repairs and equipment, was \$2.44 per diem a patient. For maintenance of patient only, \$1.13. Sixty-three children were cared for during a total of 4,926 days.

2. **Ear Affections in Children.**—Jarecky calls attention to the importance of promptly diagnosing and vigorously treating the ear affections of children. The possible consequences of neglect are emphasized.

3. **The Widal Test.**—Borden does not discuss the real Widal test, but the method of testing for typhoid fever based on the precipitation of dead typhoid bacilli, held in suspension in a proper medium by means of the serum of typhoid patients. The author gives (1) a method of making the suspensions of dead bacilli and (2) a method of using it. The paper is based on original work performed at the Presbyterian Hospital. The author concludes: (1) The method is to be adapted to use by the practising physician because its technics is simple and free from danger, and because the reading of the reaction is absolute. It is either positive or negative. For the diagnosis laboratory it seems specially fitted because requiring so little time for its application. (2) It is possible that a similar suspension of characteristic bacteria may be used in the diagnosis of diseases other than typhoid fever. (3) The methods of collection and dilution suggested are thought to be simpler and more rapid than those heretofore employed.

4. **Prostatectomy.**—Fowler asserts that no hard and fast rule can be laid down for guidance in choosing between suprapubic and perineal prostatectomy. The latter method is, however, generally to be preferred. The author describes briefly his method of doing an enucleation and a resection. He does not believe that any instrument is ever needed for the purpose of dragging the prostate into the wound. It is probable that the instruments which make pressure upon the prostate from within the bladder are at times responsible for the paralysis of the vesical sphincter so frequently observed.

6. **Examination of the Back.**—Arnold asserts that in every case of disease, whether acute or chronic, marked indications will be found by a

careful examination of the spine in the region supplied by the posterior primary divisions of the spinal nerves corresponding to those segments of the spinal cord from which the affected parts derive their innervation. No part of the body can be functionally or structurally diseased without there being a disturbance either primarily or secondarily in those segments of the cord from which the part receives its nerve supply, and these diseased conditions invariably express themselves by indications which can be readily detected along the spinal column by a careful examination. The author gives general directions which will enable any one to test the truth of his assertions. As it is somewhat difficult to find in the ordinary textbooks the data essential to the location in the spinal cord of the nervous mechanisms of different parts of the body, he has appended to his paper a brief description of the nervous mechanisms of the different parts of the body and the segments of the cord from which they arise.

AMERICAN MEDICINE.

March 18, 1905.

1. Cholecystitis as a Complication of Lobar Pneumonia: with a Report of Three Cases, and Remarks on Icterus in Pneumonia, By J. M. ANDERS.
2. Primary Tuberculosis of the Female Breast, with Report of a Recent Case, By G. W. SPENCER.
3. A Dissertation on Temperament, Diathesis, Dyscrasia, Predisposition, Cachexia, Susceptibility, Idiosyncrasy, and Heredity (*To be continued*), By HOMER WAKEFIELD.
4. Surgical Treatment of Bright's Disease, By W. HERSHEY THOMAS.
5. Ætiology and Pathology of Bright's Disease, By W. E. ROBERTSON.
6. Postoperative Nasal Hæmorrhage; Calcium Chloride; Secondary Anæmia: Rapid Recovery, By REYNOLD WEBB WILCOX.

1. **Cholecystitis and Pneumonia.**—Anders presents notes of three cases of pneumonia complicated by cholecystitis. Two of the patients recovered and one died. The diagnosis was based entirely on the clinical pictures presented. It would, therefore, be unwise to draw too definite conclusions. Jaundice in pneumonia has been observed not infrequently. Opinion varies as to its origin. It has been assumed to be due to blood destruction. This is not probable. Most reliable modern opinion is to the effect that icterus is a symptom or complication of pneumonia only when a catarrhal (mechanical) obstruction of the biliary passages occurs. This obstruction may be confined to the intrahepatic biliary canaliculi. Similarly, the jaundice accompanying cholecystitis is caused by the associated catarrhal infection of the bile ducts.

2. **Tuberculosis of the Breast.**—Spencer reports one case which he believes was primary. Diagnosis is at times difficult before operation, the condition resembling closely a chronic mastitis of indefinite origin. In the author's case tubercle bacilli were demonstrated in the excised tissues. According to the author proper treatment consists in removal, in one piece, of the entire breast, together with the skin overlying

the diseased focus, and the glands, fat, and fascia from the axilla.

4. **The Surgical Treatment of Bright's Disease.**—Thomas reviews the history of the surgical treatment of Bright's disease from the time of Harrison's first publication in 1896. The bulk of the paper is an exposition of the views set forth by Edebohls. The author concludes that with the exception of nephrotomy for renal calculi and the drainage of abscess, and nephrectomy for the excision of renal tumors, renal decapsulation is to be preferred to all other surgical procedures upon the kidney, for the following reasons: 1. No damage whatsoever is done to important secreting structures. 2. It involves less danger from hæmorrhage. 3. Other things being equal, it is to be preferred on account of the greater simplicity of wound treatment. It should also be noted that renal decapsulation has now been employed between 200 and 300 times, and that so distinguished a surgeon as Roswell Park advises decapsulation of every kidney operated upon for any reason.

6. **Calcium Chloride.**—Wilcox reports the case of a man who four days after an intranasal operation began to bleed profusely from the nose. Packing did not control the hæmorrhage and the patient's condition soon became desperate. He was then placed on calcium chloride, forty grains in one dose, each day. Soon after this treatment was instituted the bleeding became controllable. The author has always had good results from the use of calcium chloride when it is administered in single large daily doses either by the mouth or by the rectum.

LANCET.

March 4, 1905.

1. The Changes Produced by Inflammation in the Conjunctiva. (*Hunterian Lectures, I*), By M. S. MAYON.
2. Peritonitis, a Bacteriological Study. (*Erasmus Wilson Lectures, II*), By L. S. DUDGEON and P. W. G. SARGENT.
3. Plastic Surgery, By C. R. B. KEETLEY.
4. The Treatment of Severe Curvatures in the Tibiæ by Means of Manual Osteoclasia, By T. H. OPENSRAW.
5. The Cause of Pain in Cases of Gastric Ulcer and Its Bearing Upon the Operation of Gastrojejunostomy, By C. W. M. MOULLIN.
6. A Case of Recurrent or Successive Ovarian Papilloma with Sequent Ventral Hernia, followed by Cervical Epithelioma; Two Abdominal Cæliotomies; Operation for Ventral Hernia; Vaginal Hysterectomy; Recovery, By E. S. BISHOP.
7. The Medical Man as Expert Witness, By W. B. RANSOM.

1. **Conjunctivitis.**—Mayon begins the Hunterian lectures on the changes produced by inflammation in the conjunctiva, with an account of the development of the conjunctiva, passing on to the histological changes which occur in inflammations. The result of his investigations has been to lead him to agree with Whitfield's opinion that the endothelial and perithelial cells play an important part in the production of mononuclear leucocytes and plasma cells.

2. **Peritonitis.**—Dudgeon and Sargent, in the second of the Erasmus Wilson lectures, take up the bacteriology of appendicitis. The chief interest in this subject centres around the colon bacillus. Many observers, however, hold that the colon bacillus is an organism which is very easy to cultivate and grows very rapidly and, therefore, the more delicate but more virulent organisms are never isolated. It is the streptococcus pyogenes, the pneumococcus, and the "staphylococci" which are supposed to be most easily outgrown by the bacillus coli. In not a single instance among their cases did the writers obtain the streptococcus pyogenes from the peritoneal cavity in acute diffuse non-perforative peritonitis due to appendicitis. Further, in those cases in which the streptococcus is found in the peritoneal cavity the prognosis is practically hopeless. If this organism were, therefore, frequently present in the peritoneal exudate in appendicitis the mortality would be very much higher than it is at present. In only one case was the pneumococcus isolated, and then in association with the colon bacillus; so that the pneumococcus cannot be the important organism in appendicitis that it has been assumed to be by some. The usual tendency of the pneumococcus is to produce diffuse peritonitis without any of the changes which are met with in perforative peritonitis. As regards the pathogenic staphylococci they have found the white staphylococcus in almost every variety of peritonitis; it is by far the most common organism met with in the peritoneal exudate at a distance from the site of origin of the acute lesion, and is frequently found in the peritoneal cavity in the "interval cases" of appendicitis. The important bearing which it is found to have on the prognosis of a case of peritonitis when present in the peritoneal exudate alone or some time previously to the arrival of the colon bacillus, cannot be overestimated. It does not appear to have any influence in the prognosis of those cases which are due to the streptococcus pyogenes or bacillus pyocyaneus. The chief results which arise from injecting the white coccus into the peritoneal cavity of animals are the production of an extensive phagocytosis and also a selective action of the body fluids. In only one instance did the authors find an anaerobic organism. This was the bacillus aerogenes capsulatus of Welch, and was isolated from the pus of an abscess in which the appendix was found to be gangrenous. The bacillus pyocyaneus appears to be extremely virulent when present in the human peritoneal cavity. It does not produce the green pus in the peritoneum, such as is often seen in a local abscess. Virulent cultures which kill the patients in a few days do not usually produce any chromogenic staining of the pus. In the large majority of cases the bacillus pyocyaneus causes death when present in the peritoneal cavity, and is only less virulent than the streptococcus pyogenes in that it takes a little longer to cause death. In every variety of appendicitis the colon bacillus is the most important pathogenic organism. In nearly every instance more than one strain of this bacillus is present, either in the abscess, peri-

toneal exudate, or elsewhere. And these various strains differ in virulence. If during an interval operation for appendicitis the colon bacillus be allowed to escape into the peritoneal cavity probably fatal peritonitis will ensue. The colon bacillus will not grow in the presence of the bacillus pyocyaneus, being always outgrown and destroyed by the latter. The colon bacillus is less virulent than the bacillus pyocyaneus and much less so than the streptococcus pyogenes. If present alone in the peritoneal exudate "at a distance" then the prognosis is extremely grave, while if the phagocytes are all degenerated then the prognosis is practically hopeless. The co-existence of the staphylococcus albus renders the prognosis less grave, though still very bad. As regards the rôle of the phagocytes in peritonitis, the authors assert that they are able to show that the coarsely granular eosinophile cell, which most observers have considered to be non-phagocytic, is one of the most important phagocytes in the early stages of peritoneal infection, while the finely granular polynuclear cell becomes the important phagocyte in the later stages of peritonitis. Washing out the peritoneal cavity in cases of peritonitis does harm in that the phagocytes are washed away, new organisms are allowed to enter, and the original infecting organism is carried still further into the recesses of the peritoneum. The small lymphocyte was also shown to possess phagocytic powers.

5. **Gastric Ulcer.**—Moullin states that the reason for the intensity of the pain in so many cases of gastric ulcer is because the inflammation, starting from the lymphatics that drain the region of the ulcer, spreads to the parietal peritoneum and makes it infinitely more sensitive. And the cause of the pain is the pull of the stomach on these inflamed sensitive areas, so that it is naturally felt most severely when the pyloric end of the stomach is at work.

BRITISH MEDICAL JOURNAL.

March 4, 1905.

1. The Prospects and Vicissitudes of Appendicitis After Operation, By SIR F. TREVES.
2. Some Peculiarities of Appendicitis in the Female Sex, with Special Reference to Appendicitis Occurring During Pregnancy, By G. HEATON.
3. The Relationships Between Colitis and Appendicitis from a Surgical Point of View, By C. B. LOCKWOOD.
4. The Operative Treatment of Certain Severe Cases of Indigestion, By W. B. CLARKE.

1, 2, 3. **Appendicitis.**—Treves, in his article on appendicitis, discusses the degree of imperfect relief or of imperfect recovery after operation, and the complications which may attend operation and are independent of the direct surgical results of the case. He first suggested, in 1887, the removal of the appendix during the quiescent period. Since then he has observed a number of cases in which attacks occurred after the removal of the appendix: of forty-five such cases, there was coexisting ovarian trouble in nine, persisting or relapsing colitis in eight, persisting local pain

in seven, and neurasthenia in five. It is almost impossible to distinguish between chronic appendicitis and chronic oophoritis. In operations upon women the right ovary should be systematically examined when the appendix is being removed: a somewhat larger opening than usual should therefore be made in these cases. The association of colitis and appendicitis is common. The colon trouble may be primary and lead, by extension, to inflammation of the appendix. Or in cases of chronic appendicitis, the appendix may act as a culture tube for bacteria, the contents of which are emptied from time to time into the cæcum, setting up trouble there. Ventral hernias are quite common after evacuation of perityphlitic abscesses: other imperfect results are persistent sinuses, recurring abscesses, recurring attacks of appendicitis, and fecal fistulæ. The persisting sinus, in the majority of instances, is due to a diseased appendix, or to a retained concretion. The relapsing abscess is due, almost without exception, to the same causes. The original collection of pus is evacuated and drained; the wound heals; after a varying period of time the patient has pain and tenderness in the part with fever and constipation; a second abscess appears and is opened. The writer has known the abscess to appear ten times before the patient was dealt with by radical operation. In a few instances there is no apparent abscess, but in its place a troublesome inflammatory mass in the iliac fossa or pelvis. While fecal fistulæ exist another attack of appendicitis is exceedingly uncommon. The fistula, unless due to cutting or tearing of the bowel, has a tendency to close spontaneously. The fistulæ which appear some days after the evacuation of the abscess do better than those which are evident at the time of the operation. A still diseased appendix or a retained concretion is often the cause of the persistence of the fistula. While the appendix should be removed in every case in which it gives the least trouble, yet the following facts are urged against its removal in every case of abscess: 1. Only seventeen out of a hundred cases ever have a second attack. 2. The mortality of second attacks is comparatively small; about seven per cent. 3. The operation is often not only very difficult, but distinctly dangerous. With the exception of fecal fistula, intestinal obstruction, and persisting or extending abscess, the principal complications which may attend operations for appendicitis are those only of septic infection. Pylephlebitis occurs, and also pleurisy and empyema from direct local extension of inflammation from the original seat of infection. The parotiditis is probably due to oral sepsis. The common thrombosis of the left femoral vein cannot be readily explained: it may be due to the increased use of the left thigh after the operation, as compared to that of the right side. Of ten patients who were the subjects of appendicitis, and were operated on for acute intestinal obstruction, six died. After an appendix abscess has been opened and drained, other abscesses may form: these fall into three groups: 1. The residual abscess, in which a reaccumulation of pus takes place underneath or close

to the operation scar: no signs of another attack of appendicitis. 2. The secondary abscess, the result of the direct extension of the inflammatory process from the primary abscess. 3. The abscess which accompanies subsequent attacks of appendicitis.

Heaton discusses appendicitis as it occurs in women, especially during pregnancy. The disease is much commoner in men than in women. Pregnancy does not seem to predispose to a primary attack of appendicitis, but may light up a secondary one, by stretching and breaking down old inflammatory adhesions. Pregnancy greatly increases the risks and dangers of the disease: the further advanced the pregnancy the worse the prognosis. If suppuration takes place the risk to life increases enormously; miscarriage almost invariably takes place, and the risk of general septic peritonitis is extremely grave, all limiting adhesions being broken down. The attack may occur at any stage of pregnancy, and may be of all degrees of severity. The mild cases may be mistaken at first for the vomiting of pregnancy. These cases of appendicitis in pregnancy seem to run an unusually rapid course, and it should be an invariable rule to operate at once, without waiting for the evidence of pus formation. The uterus and pelvic viscera are to be disturbed as little as possible. When general septic peritonitis already exists the prognosis is almost hopeless. It is not necessary or advisable to empty the uterus after opening the appendicular abscess. But abortion takes place in 86 per cent. of the cases. In all cases of miscarriage a history of appendicitis should be sought for. The appendix is also probably responsible for many so called attacks of right sided pelvic peritonitis in women. In relapsing appendicitis in young women the attacks of pain frequently occur just before or at the menstrual period, and are determined by the congestion of the tube and ovary. Appendix, ovary, tube, and omentum are frequently found at operation adherent to one another.

Lockwood discusses some of the forms of colitis from a surgical point of view, and especially in their relation to appendicitis. The relation of simple mucous colitis to appendicitis is a mere question of extension by proximity, and the bowels soon recover when the appendicitis has ceased. But where the mucous colitis is primary and due to coprostasis, the colitis does not disappear with the appendicitis, but only when the fecal lumps have been removed.

4. **Abdominal Operations.**—Clarke discusses the operative treatment of severe indigestion, and lays down the following propositions: 1. Ruptured gastric and duodenal ulcers should always be treated surgically without delay. 2. Severe cases of hæmorrhage which threaten life should likewise be treated by opening the belly and securing the bleeding point or points. 3. When chronic ulcers of the stomach and duodenum cease to improve under medical treatment, surgical interference is indicated and is capable of affording much relief.

Proceedings of Societies.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Meeting of February 1, 1905.

The President, Dr. ARTHUR V. MEIGS, in the chair.

Recent Advances in the Technics of Röntgen Therapy.—Dr. CHARLES LESTER LEONARD read a paper with this title. In considering the apparently antagonistic results published in reference to Röntgen therapy he said it must be remembered that positive evidence was more valuable than negative. Cures could not be alleged as yet, but an inhibitory action had been absolutely demonstrated. The apparent variation in results he explained by variations in the technics and experience of the operator. The effective dose he considered difficult to arrive at, because it must be strong enough to injure pathological cells and yet not too strong for normal tissues. In addition, varying qualities of the Röntgen ray produced different effects, and the quality must be adapted to the individual lesion. The physiological action was stimulant and alterative. In large doses it stimulated the autolytic ferments within pathological cells, which resulted in their dissolution and absorption. The difficulty in administration lay not only in adapting the proper quality of ray and dose to the individual lesion to be treated, but also in the fact that the clinician must know how to produce the dose with a complicated mechanism and must be able to recognize when the right quality and quantity were being employed by their clinical effects. While any dose and any technics would produce some effects, exact dosage was essential to the efficient employment in difficult cases, and, as with all other powerful remedies, clinical experience in adapting the dose to the individual patient counted in the final result. Increased knowledge and improved technics had recently made marked advances in treatment possible and promised greater efficiency.

The Treatment of Non-Malignant Diseases by the Röntgen Ray.—Dr. RUSSELL H. BOGGS, of Pittsburgh (by invitation), presented this paper. He called attention to the necessity of distinguishing between the non-malignant diseases which should and those which should not be treated with the x ray. While the continual cry of technics might become tiresome to some who thought the subject could be mastered speedily, the method of application of the rays and the judgment of the operator accounted largely for successful or unsuccessful work. It was just as essential to administer a therapeutic dose when applying Röntgen rays as it was when prescribing powerful drugs. It should be remembered that it was not so much the x ray that cured as the judgment with which it was employed. He considers the x ray one of the best therapeutic agents known for the treatment of acne and many other skin diseases, but he thought it not necessary in many instances to treat the trivial and

less obstinate cases by this method, since cures might be effected with other treatment causing less inconvenience to the patient. For the treatment of lupus he regarded the x ray, supplemented by the Finsen light, as the most efficient therapeutic agent. He also considers the use of the x ray the most efficient treatment for tuberculous glands, Hodgkin's disease, and selected cases of goitre.

The X Ray Treatment of Malignant Growths.—Dr. ENION G. WILLIAMS, of Richmond, Va. (by invitation), read this paper. He said that the results of the practical use of the ray as reported by the different operators had differed greatly; the general profession had been misled by the over-enthusiastic as well as by the pessimistic operators, so that the true value of the ray had yet to be found out. To determine the therapeutic value of the ray, it was necessary to consider, first, the factors concerned in its production and variation and the methods of the application in treatment; secondly, the histological changes due to it; and, thirdly, the nature and situation of the growth to be treated. The tissues most influenced by the ray were those having a large proportion of cells whose vital processes were very active, tissues as were found chiefly in malignant tumors, carcinoma and sarcoma. Benign tumors, composed largely of intercellular substance with a small proportion of cells not actively proliferating, were therefore only slightly or not at all influenced by the ray. From his observations he concluded that the prognosis depended upon the character of the growths and upon their accessibility to the proper quantity of radiant energy. He believed that the ray was indicated in superficial growths. For deep growths, until there could be shown more uniformly good results, radical surgical procedures should be recommended, to be followed by sufficient x ray exposure to destroy malignant cells several inches from the surface. "Inoperable" cases should be treated, because of the remarkable results in the relief of pain which had been noted.

Dr. GEORGE C. JOHNSTON believed the time had come to make inquiry concerning the merits of the x ray as a remedial agent. Many of the allegations put forth he attributed to over-enthusiasm and inexperience. On the other hand, there was a mass of evidence put forth by some of the best men of the profession, men of age, experience, and mature judgment, whose opinions were worthy of acceptance. The success or failure in the application of the agent depended upon the dose, and the dose of the x ray was composed of several factors: (1) The length of time the agent was allowed to act; (2) the distance from the source of the ray to the patient; and (3) the degree of vacuum of the tube emitting the ray. The third factor was incapable of any accurate measurement short of actual observation of the radiation itself. Another factor was penetration, and this must be adapted to the depth it was desired to reach. Since some tubes produced a burn easily, Dr. Johnston advised beginners to test every tube in radiographic work before using it on a patient. The test might cost them fifty cents; if tested on

the patient, possibly \$50,000, if the operator had it. In radiographic work the x ray man must have a certain technics, with every detail of which he must be familiar. In radiotherapeutic work he must have a technics more exact and capable of immediate variation to suit individual cases.

Dr. Johnston's position was that the legitimate x ray man did not consider himself the successor of the obsolete surgeon, but was proud to be accorded the position of qualified assistant to the surgeon, believing that he had at his command an agent which would afford the surgeon better results in his malignant cases. A postoperative radiation was frequently effective in removing a possible focus of disease, and he had demonstrated to his own satisfaction its power of inhibiting the growth of malignant tissue. The management of postoperative radiation should not be left to an assistant or nurse, but be under the charge of a thoroughly qualified x ray operator.

The future of malignancy, Dr. Johnston believed, depended upon the general practitioner, because he saw the cases first. Personally, he found that each month he had more of the early cases of cancer, such as cancer of the breast, sent to him for treatment. His recommendation in such cases was a Halsted operation and radiotherapy to prevent recurrence. He had cases *apparently* cured by this method, which remained so. He preferred to call them cases of inhibition, more or less permanent, with the hope that it would remain permanent. The need of x ray workers, he said, was the cooperation of the surgeons and pathologists. As soon as all worked together in harmony, malignancy and other diseases would present a brighter future.

Dr. JOHN B. SHOBER said that in his experience with x ray work he had seen mostly the cases of malignant disease in women, and in six or seven cases of "inoperable" carcinoma of the cervix he had noted the inhibitory action of the agent. In one case of recurrence following hysterectomy for carcinoma of the uterus, treated by the x ray and radium, the growth, which was of the size of an English walnut, disappeared in the course of ten weeks and there was no sign of recurrence. In a case of carcinoma of the breast in which the patient had positively refused an operation, Dr. Shober undertook the treatment by the x ray, with the understanding that the patient would consent to an operation if the growth developed under treatment. The growth increased in size, but softened and then diminished in size, and there ultimately remained no sign, except a small induration, possibly the result of an accumulation of fibrous tissue in the site of the disease.

Dr. GEORGE EREY SHOEMAKER considered that after the surgeon's work was finished he owed the duty to his patient of having the x ray applied for a definite time. From his own experience with cancer of the uterus he would advise, first, the cautery, after that, surgical excision of the part, including the cautery scar, and after that, the x ray. This treatment, he thought, offered the most hope in a field which had been discouraging.

Dr. W. S. NEWCOMET referred to the value of the x ray as shown in desperate cases. He showed on the screen the picture of a case of trachoma in a girl of about sixteen which had existed since the age of three months. She had been able to count fingers only in the light. As the result of the x ray treatment she could now see a distance of two or three blocks.

Dr. LEONARD said that the papers of the evening showed the results achieved. Since the development of the technics he felt that much more might be expected from the treatment, and he believed that the future was brighter than the past in regard to the value of the x ray. An agent which showed itself capable of inhibiting a growth should be carefully studied, not only by the x ray men, but by the general profession.

Book Notices.

The Diseases of Society. (The Vice and Crime Problem.) By G. FRANK LYDSTON, M. D., Professor of Genitourinary Surgery, State University of Illinois, etc. Philadelphia: J. B. Lippincott Company, 1904. Pp. 626. (Price, \$3.00.)

The author states that this work has been in preparation for many years, and that he presents what he believes to be truths that have been gleaned from study and observation of sociology, criminology, criminal anthropology, and penology in so far as they bear upon social disease in its various manifestations.

After a general consideration of the subject in the first chapter, which is entitled social pathology, the author considers the principles of evolution in their relations to criminal sociology and anthropology. In discussing the relation of theology and religion to social evolution he commends the Salvation Army for its excellent work, and properly holds that some expounders of peculiar and fanatical creeds, by diverting vacillating minds into safe channels, are powerful factors for practical moral good.

The author concludes that no single factor operates alone in the production of a special form of social disease, but that several of some twenty different causes are usually combined. We shall all agree to this dictum in the section on suggestion and crime: "It would certainly be illogical and unfair to the press to hold it responsible for the flotsam and jetsam among its readers. It should, however, be held responsible where it takes advantage of the specific gravity of morals and caters to the baser elements of normal man, and, more especially, the morbid tastes of the degenerate."

The chapter on neuroses in their relation to social diseases is a very interesting review of brain development, the criminal skull and brain, several mental diseases, and suicide.

Under the heading of the chemistry of social diseases is described the relation of alcoholic, narcotic, and autogenetic toxemia to vice and crime.

There is much that is suggestive in the chapter on anarchy in its relations to crime, the author holding that there is a governmental, political, and municipal anarchy, an anarchy of capital as well as of labor, and even an anarchy of law.

The profession must cry *peccavi* to the charge, in the chapters on sexual vice and crime, that: "Reputable medical men have ever been remiss in their duties to the public so far as instructing it in sexual matters is concerned." We agree with the author that it is unjustifiable and false to accuse the medical profession of aiding and abetting prostitution by advising fornication. It is the duty of the physician to suggest continence rather than prophylaxis. Experience has proved that the regulation of prostitution and inspection of prostitutes do not decrease the spread of venereal diseases; if the medical profession ignores this fact and endorses the former measures, it will, by minimizing the fear of disease from promiscuous intercourse, remove one of the most powerful checks on the spread of the social evil. There are those who will think that the author is simply in advance of his epoch in advocating the desexualization of certain criminals.

Dr. Lydston believes that genius is abnormal, that it is both a product and a cause of degeneracy, and that it is correlated with other phenomena of degeneracy that are recognized generally as social diseases, so he has written an entertaining chapter on genius and degeneracy.

While in the chapters on the characteristics and on the types of the criminal the author professes an agnostic attitude, the impression one has from the reading is that he inclines to the school of Lombroso in attaching importance to the so called stigma of degeneracy.

The final chapter, on the therapeutics of social disease, is most interesting, and there are few physicians who will not agree as to the academic value of the remedial measures that are advanced, though their practicability is hampered by the prejudices and conservatism of society. The book is worthy of the author's reputation, and it deserves and is likely to have a wide discussion.

Miscellany.

Hallucinations.—Dr. William A. White, in the *Journal of Nervous and Mental Diseases*, for November, 1904, gives the clinical history of ten cases which leads to four conclusions:

1. Hallucinations are false perceptions. This implies that there must be something to perceive and that something is in the environment and can enter as a factor into the mental life only through the intermediation of sensations. Ideas cannot be perceived.

2. Hallucinations are secondary sensations either arising in the same sensory field, in which case they might be described as illusions in the sense of Esquirol, or arising in other sensory fields, in which case their secondary character is quite clear.

3. The mental state in illusions and hallucinations is the same.

4. Given the sensory elements the falseness in their perception is due to central derangement. The several theories of hallucinations, particularly those which attribute their origin solely to centric disturbance with reverse currents in the sensory nerves, go a long way around, and take great pains to find an explanation which in real-

ity is close at hand. Titchener estimates that there are more than 44,435 elementary sensations or sensation qualities appreciable by the various sense organs, and says, furthermore, "each one of these 40,000 qualities is a conscious element, distinct from all the rest, and altogether simple and unanalysable. Each one may be blended or connected with others in various ways to form perceptions and ideas. A large part of psychology is taken up with the determination of the laws and conditions which govern the formation of the sensation complexes."

The sensory elements of perception in whole or in part have but a marginal or subconscious value. But because they may have been displaced from the focus of clear perception, relatively or absolutely, because perhaps they cannot be replaced except by a special effort, or perhaps not at all, they are none the less real. Many sensations are normally not appreciated at all, either because of their weakness or because of the preponderance of some other sensations. In fact, this is an absolutely necessary condition for mental concentration. If it were otherwise and all sensory impulses were appreciated at their full value, coherent thought would become impossible. Thus it is that sensations that under ordinary circumstances would hardly, if at all, rise above the threshold of consciousness, may acquire an unusual value, and being thus out of harmony with the actualities they represent, a false perception is the result. This is especially well shown in the phenomena of dream consciousness.

It is necessary, in order that the particular sensory stimulus receive the specific interpretation that stamps it as a hallucination that there be a certain state of preparedness on the part of the mind. The mind of the patient with tinnitus aurium who hears a voice is especially attuned to respond in that particular way.

The author has never failed to find a peripheral pathological process in all hallucinated cases which he has examined which could explain directly or indirectly the hallucinatory phenomena. The peripheral process need not be pathological in order to account for a hallucination, as in the dream hallucination and the hypnotic hallucination, but it is hardly conceivable that the auditory hallucinations of a paranoiac which are practically constantly present, unless the patient's attention is distracted, could be produced by other than a constant irritant, which would necessarily be pathological in origin. Hence the necessity of careful and painstaking examination of all hallucinated cases. With all the possibilities in view the author would be unwilling to accept other than a peripheral explanation of any hallucinated case.

The Circumstances and Treatment of Movable Kidney.—Treves, in the *Practitioner*, for January, 1905, refers to this condition as a malady of modern times. Glénard says it occurs in 22 per cent. of adult females, and is more frequent on the right than on the left side.

The first reliable clinical description of this condition was made by Rayer in 1839. It is com-

mon in women with weak muscular development and especially in those who have borne many children. In the majority of cases it is attended with diminution of the circumferential fat. It may result from injury, from violent exercise, etc. In making a diagnosis the patient may lie on the back while the examiner presses the loin in front and behind, just below the costal arch, with the extended fingers of the two hands, the right in front and the left behind. As the patient takes a deep inspiration, the movable organ slips downward, and as the fingers close upon it, it may be felt to glide away. The patient may then lie upon the sound side when the movable organ will be found near the median line by the compressing fingers of the two hands. A further examination should also be made in the standing position. Glénard observes four degrees of descent of the organ. In the fourth or extreme degree there is rotation and almost a transverse position of the organ. A kidney which is displaced may become the seat of hydronephrosis, while its ureter may be bent or twisted. A distended gall bladder is sometimes mistaken for a movable kidney, but the two conditions may co-exist. Symptoms may be absent, or there may be severe pain, irritability, nausea and vomiting, a sensation of dragging in the abdomen, flatulence, constipation, indigestion, etc. Nephrorrhaphy is not demanded in the great majority of cases, and though the risk to life from the operation is small, and success attends the large majority of operations, it should be the last and not the first resource.

It is imperative when there are torsion symptoms and when ordinary methods of treatment have failed to bring relief, such methods including rest in the recumbent position, with careful feeding, careful attention to the digestive organs, and general massage.

If a truss is properly made, and so adjusted that pressure is directed upward and outward upon the organ, the kidney may be kept securely in position. The author has made use of such a truss in more than 300 cases with perfect satisfaction, and has abandoned the operative treatment of this condition, except in urgent cases or those in which the truss could not be satisfactorily worn.

Official News.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended March 17, 1905:

Smallpox—United States.			
Places.	Date.	Cases.	Deaths.
Dist. Columbia—Washington.	Mar. 4-11.	3	
Florida—Jacksonville.	Mar. 4-11.	1	
Georgia—Macon.	Mar. 4-11.	1	1
Illinois—Chicago.	Mar. 4-11.	6	
Illinois—Danville.	Mar. 4-11.	16	
Kentucky—Louisville.	Mar. 2-9.	4	
Louisiana—New Orleans.	Mar. 4-11.	17	
Five imported.			
Michigan—Detroit.	Mar. 4-11.	1	
Michigan—At 187 places.	Feb. 4-11.	38	2
Missouri—St. Louis.	Mar. 4-11.	38	
New York—Mount Vernon.	Mar. 4-11.	1	

New York—New York.	Mar. 4-11.	1	
Ohio—Zanesville.	Jan. 25-Feb. 4.	1	
South Carolina—Charleston.	Mar. 4-11.	2	
South Carolina—Greenville.	Feb. 25-Mar. 11.	20	S
Tennessee—Memphis.	Mar. 4-11.	7	
Tennessee—Nashville.	Mar. 4-11.	1	
West Virginia—Wheeling.	Feb. 25-Mar. 4.	1	
Wisconsin—Milwaukee.	Feb. 25-Mar. 11.	28	

Smallpox—Foreign.			
Brazil—Bahia.	Jan. 21-Feb. 16.	27	2
Brazil—Paris.	Jan. 29-Feb. 12.	47	Present.
Brazil—Rio de Janeiro.	Jan. 29-Feb. 12.	47	22
China—Shanghai.	Jan. 22-Feb. 4.	15	foreigners, 55 deaths, natives.
Ecuador—Guayaquil.	Feb. 14-21.	2	
Ecuador—Porte Viejo.	Feb. 23.	Present.	
France—Paris.	Feb. 18-25.	23	
Great Britain—Birmingham.	Feb. 18-25.	3	
Great Britain—Glasgow.	Feb. 27-Mar. 3.	2	
Great Britain—Hull.	Feb. 4-11.	2	
Great Britain—Leeds.	Feb. 18-25.	4	
Great Britain—Leith.	Feb. 18-25.	1	
Gt. Britain—Newcastle-on-Tyne.	Feb. 18-25.	11	
Great Britain—Nottingham.	Feb. 18-25.	1	
Great Britain—South Shields.	Feb. 18-25.	5	
India—Bombay.	Feb. 7-14.	124	
India—Calcutta.	Feb. 7-14.	2	
India—Karachi.	Feb. 5-12.	3	
India—Madras.	Feb. 4-10.	2	
Italy—Catania.	Feb. 18-25.	1	
Norway—Christiania.	Feb. 11-25.	3	
Russia—Moscow.	Feb. 4-18.	13	4
Russia—Odessa.	Feb. 11-18.	2	1
Russia—St. Petersburg.	Feb. 4-11.	5	
Spain—Barcelona.	Feb. 10-9.	20	
Turkey—Constantinople.	Feb. 12-19.	4	
Uruguay—Montevideo.	Feb. 7.	Epidemic.	
West Indies—Grenada.	Feb. 9-23.	10	

Yellow Fever.

Ecuador—Guayaquil.	Feb. 14-21.	4	
Panama—Panama.	Jan. 1-Mar. 4.	33	14

Plague—Foreign.			
Brazil—Rio de Janeiro.	Jan. 27-Feb. 12.	20	6
India—Bombay.	Feb. 7-14.	587	
India—Calcutta.	Feb. 4-11.	106	
India—Karachi.	Feb. 5-12.	54	52

Public Health and Marine Hospital Service:

List of the Changes of Station of Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending March 15, 1905:

BARNES, W., Acting Assistant Surgeon. Granted leave of absence for two days from March 15th.

BERRY, T. D., Assistant Surgeon. To report to chairman of board of examiners at Washington, D. C., March 27, 1905, for examination to determine his fitness for promotion to the grade of passed assistant surgeon.

BILLINGS, W. C., Passed Assistant Surgeon. Granted extension of leave of absence for five days from March 17th.

BOGESS, J. S., Assistant Surgeon. Granted leave of absence for four days from March 21st.

EBERSOLE, R. E., Assistant Surgeon. Granted leave of absence for ten days from March 15th.

FRANCIS, EDW., Assistant Surgeon. To report to chairman of board of examiners at Washington, D. C., March 27, 1905, for examination to determine his fitness for promotion to the grade of passed assistant surgeon.

HAMMOND, A. P., Acting Assistant Surgeon. Granted leave of absence for five days from March 7, 1905, under paragraph 210 of the regulations.

LONG, J. D., Assistant Surgeon. To report to chairman of board of examiners at Manila, P. I., May 15, 1905, for examination to determine his fitness for promotion to the grade of passed assistant surgeon.

MATHEWSON, H. S., Passed Assistant Surgeon. Granted leave of absence for five days from March 13th.

McCoy, G. W., Assistant Surgeon. To report to chairman of board of examiners at Manila, P. I., May 15, 1905, for examination to determine his fitness for promotion to the grade of passed assistant surgeon.

MCLAUGHLIN, A. J., Assistant Surgeon. To report to chairman of board of examiners at Washington, D. C., March 27, 1905, for examination to determine his fitness for promotion to the grade of passed assistant surgeon.

STONER, G. W., Surgeon. Granted three days' leave of absence under paragraph 191 of the regulations.

WALKLEY, W. S., Acting Assistant Surgeon. Granted leave of absence for two days from March 16th.

WARREN, B. S., Assistant Surgeon. To report to chairman of board of examiners at Washington, D. C., March 27, 1905, for examination to determine his fitness for promotion to the grade of passed assistant surgeon.

WICKES, H. W., Passed Assistant Surgeon. To rejoin station at Reedy Island Quarantine.

WILSON, R. L., Passed Assistant Surgeon. Relieved from duty at the Hygienic Laboratory. Bureau letter of February 8th, granting Passed Assistant Surgeon Wilson leave of absence for one month from March 1, 1905, amended so that said leave shall be for twenty-three days.

Boards Convened.

Board convened to meet at Washington, D. C., March 27, 1905, for the examination of assistant surgeons. Detail for the board—Assistant Surgeon General G. T. VAUGHAN, chairman. Surgeon D. A. CARMICHAEL. Passed Assistant Surgeon JOSEPH GOLDBERGER, recorder.

Board convened to meet at Manila, P. I., May 15, 1905, for the examination of assistant surgeons. Detail for the board—Passed Assistant Surgeon V. G. HEISER, chairman. Passed Assistant Surgeon CARROLL FOX. Passed Assistant Surgeon C. W. VOGEL, recorder.

Bureau letter of March 8, 1905, convening a board to meet at San Francisco, Cal., April 3, 1905, for the examination of assistant surgeons, revoked. March 13, 1905.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending March 18, 1905:

BARTLETT, C. J., First Lieutenant and Assistant Surgeon. Left Army and Navy General Hospital, Hot Springs, Ark., on ten days' leave of absence.

BOURKE, JAMES, First Lieutenant and Assistant Surgeon. Reported for temporary duty at Medical Supply Depot, New York city.

DE LOFFRE, SAMUEL M., First Lieutenant and Assistant Surgeon. Reports change of status from duty to on leave of absence for thirty days.

PIERSON, R. H., First Lieutenant and Assistant Surgeon. Left the General Hospital, Fort Bayard, N. M., on forty days' leave of absence.

PORTER, R. S., First Lieutenant and Assistant Surgeon. Leave of absence extended ten days.

REILLY, JOHN J., First Lieutenant and Assistant Surgeon. Granted six months' leave of absence.

SNYDER, HENRY D., Major and Surgeon. Ordered to proceed from Fort Sam Houston, Texas, to Governor's Island, N. Y., as witness before retiring board.

WILSON, WILLIAM H., Captain and Assistant Surgeon. Granted four months' leave of absence, with permission to go beyond the sea.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending March 18, 1905:

ANDERSON, F., Medical Inspector. Detached from the *Brooklyn* and ordered home to await orders.

BACKUS, J. W., Assistant Surgeon. Detached from the Naval Hospital, Portsmouth, N. H., and ordered to continue duties on the *Southerly*.

BISHOP, L. W., Assistant Surgeon. Detached from the Navy Yard, New York, N. Y., and ordered to the Naval Hospital, Portsmouth, N. H., with additional duties on the *Southerly*.

FOSTER, T. G., Assistant Surgeon. Ordered to the Naval Hospital, Norfolk, Va.

FURLONG, F. M., Passed Assistant Surgeon. Detached from the *New York*, when placed out of commission, and ordered home to await orders.

NASH, F. S., Surgeon. Appointed a surgeon in the United States Navy, from February 23, 1905.

NORTON, O. D., Surgeon. Ordered to the *Olympia*.

ROTHGANGER, G., Surgeon. Ordered to the Naval Hospital, Norfolk, Va.

SCHWEIN, L. H., Acting Assistant Surgeon. Ordered to the *Hancock*.

SMITH, G. T., Surgeon. Detached from the Naval Hospital, Norfolk, Va., and directed to await orders.

STEELE, J. M., Surgeon. Detached from the *Olympia* and ordered to the *Brooklyn*.

Births, Marriages, and Deaths.

Born.

WHALEY.—In Manila, Philippine Islands, on Monday, January 23rd, to Dr. Arthur M. Whaley, United States Army, and Mrs. Whaley, a son.

Married.

CARL—YATES.—In Kansas City, Missouri, on Tuesday, March 7th, Dr. Samuel T. Carl and Miss Alice Yates.

GALLAGHER—CALVEY.—In Cleveland, Ohio, on Tuesday, March 7th, Dr. John V. Gallagher and Miss Matilda Calvey.

NORRIS—FROTHINGHAM.—In Philadelphia, on Wednesday, March 15th, Dr. Herbert Norris and Miss Harriet Frothingham.

Died.

BRIGHT.—In Washington, D. C., on Sunday, March 12th, Dr. George A. Bright, United States Navy, in the sixty-eighth year of his age.

COMSTOCK.—In Binghamton, N. Y., on Tuesday, March 7th, Dr. James Clinton Comstock, in the forty-seventh year of his age.

CRAIG.—In Philadelphia, on Tuesday, March 14th, Dr. Albert B. Craig, in the thirty-fourth year of his age.

DOOLITTLE.—In Paris Hill, N. Y., on Thursday, March 9th, Dr. Carlos V. J. Doolittle, in the thirty-ninth year of his age.

DUNLAP.—In Cincinnati, Ohio, on Thursday, March 9th, Dr. William T. Dunlap, in the sixty-first year of his age.

EAMAN.—In Gaines, N. Y., on Saturday, March 4th, Dr. W. F. Eaman.

FRAZEE.—In Rochester, N. Y., on Saturday, March 11th, Dr. A. B. Frazee, in the forty-sixth year of his age.

GREGG.—In Boston, Massachusetts, on Tuesday, March 14th, Dr. John A. Gregg, in the fifty-seventh year of his age.

HALL.—In Rochester, N. Y., on Tuesday, March 7th, Dr. W. S. Hall, in the forty-fifth year of his age.

HOWE.—In Newark, New Jersey, on Tuesday, March 14th, Dr. Edwin J. Howe, in the fifty-sixth year of his age.

JOHNSON.—In Brockton, Massachusetts, on Thursday, March 2nd, Dr. Elizabeth Ann Johnson, in the seventy-seventh year of her age.

KEENE.—In Providence, Rhode Island, on Monday, March 13th, Dr. George F. Keene, in the fifty-third year of his age.

LOSEY.—In Rochester, N. Y., on Monday, March 13th, Dr. Charles Hamilton Losey, in the forty-third year of his age.

MEYERS.—In Philadelphia, on Saturday, March 11th, Dr. W. W. Meyers, in the sixty-first year of his age.

MOORE.—In New Haven, Connecticut, on Saturday, March 11th, Dr. James A. Moore.

MUELLER.—In Baltimore, Maryland, on Thursday, March 9th, Dr. Edward D. L. Mueller, in the seventy-second year of his age.

PRINTZ.—In St. Louis, Missouri, on Thursday, March 9th, Dr. Felix C. W. Printz, in the twenty-ninth year of his age.

RUSSELL.—In Duluth, Minnesota, on Wednesday, March 8th, Dr. Hugh Russell, in the eightieth year of his age.

SCOFIELD.—In Cincinnati, Ohio, on Tuesday, March 14th, Dr. A. W. Scofield, in the forty-sixth year of his age.

VAIL.—In St. Louis, Missouri, on Monday, March 13th, Dr. E. J. Vail, in the eighty-fifth year of his age.

WELDON.—In Paris, Tennessee, on Tuesday, March 7th, Dr. A. J. Weldon, in the seventy-fourth year of his age.

SATURDAY, APRIL 1, 1905

WHOLE No. 1374.

Original Communications.

CONCERNING THE NEW ELECTRO-CYSTOSCOPE.

By WILLIAM K. OTIS, M. D.,

NEW YORK,

PROFESSOR OF GENITOURINARY DISEASES, NEW YORK SCHOOL OF CLINICAL MEDICINE; CONSULTING SURGEON TO CHARITY HOSPITAL, ATTENDING SURGEON TO ST. MARK'S HOSPITAL, AND TO THE WEST SIDE GERMAN DISPENSARY; FELLOW OF THE NEW YORK ACADEMY OF MEDICINE, OF THE AMERICAN ASSOCIATION OF GENITOURINARY SURGEONS, OF THE AMERICAN UROLOGICAL ASSOCIATION, ETC., ETC.

The invention of the electrocystoscope, an instrument which completely revolutionized our methods of diagnosis in vesical disorders, even extending to a determination of some of the lesions situated in the kidney itself, giving definite information regarding the existence of conditions which formerly could only be surmised, or accurate knowledge acquired by means of a serious operation, may well be considered one of the great advances of modern surgery.

The credit of this brilliant invention and the perfecting of the original idea in its minutest details belongs to Dr. Max Nitze, of Berlin, and to him alone.

It differs entirely in principle, design, and scope from any method for the ocular examination of the bladder which preceded it, while subsequent instruments have been modifications only of Nitze's original conception.

Nitze conceived the idea of the modern cystoscope as early as 1876, and in 1879 presented to the profession a working instrument which, owing principally to the difficulty of obtaining proper illumination, attracted attention only among a few specialists. It was, on account of the imperfect electrical knowledge of the time, complicated in construction, its illumination being derived from an incandescent loop of platinum wire, protected from the fluid in the bladder by a piece of quill. This quill being only translucent, cut out a very large amount of light, while the

hot platinum loop necessitated a cumbersome water cooling apparatus and delicate rheostat, to prevent burning out the wire or causing injury to the bladder wall, or burning the quill, causing it to become still more opaque.

This crude affair, however, had the telescope and embodied the principles found in the best types in present use. As this instrument was exceedingly difficult to manufacture, Nitze sought the aid of Josef Leiter, an expert instrument maker of Vienna, who undoubtedly lent him valuable assistance in the construction of the cystoscope, but in no way altered its fundamental characteristics. Had it not been for the subsequent invention of the incandescent electric lamp, by Thomas A. Edison, which permitted a brilliant illumination, with a heat so gentle that it was readily conducted away by the fluid medium in the bladder, without the necessity for the accessory water cooling apparatus, the cystoscope would never have attained the position as a practical instrument which it occupies to-day.

Although it had been suggested by von Dittel in 1883, it was not until 1887 that this method of illumination was utilized. About this time a disagreement occurred between Nitze and Leiter, resulting in the appearance of two incandescent lamp cystoscopes, differing from each other only in minor details, that of Nitze, manufactured by Paul Hartwig, of Berlin, and that of Leiter of his own make.

Over twenty-five years have passed since the invention by Nitze of the electrocystoscope, and although many modifications of it have been presented during this period *no one has succeeded in improving the ocular apparatus, and the cystoscopes of to-day are no better than those manufactured by Hartwig or Leiter in 1887.*

Some six or seven years ago it was even impossible to have disabled cystoscopes repaired in this country, and the necessity of sending them abroad for this purpose was often a decided inconvenience.

About this time I was fortunate enough to make the acquaintance of Mr. Reinhold Wappler, a most skillful electrician, who had already

acquired an enviable reputation for the manufacture of medicoelectrical instruments, and together we began a series of experiments in the attempt to develop the possibilities of the cystoscope by enlarging the field and improving the illumination.

It must be remembered that the electrocystoscope presents many difficulties in the making, for not only does the workmanship require a most experienced and skillful mechanic, but in addition one who thoroughly understands the construction of electrical instruments, and above all must he have a thorough knowledge of optics and the ability to construct and even originate a complicated ocular system.

We were confronted at the outset by the inability of obtaining suitable lenses, the principal manufacturers of microscopes refusing to aid us in this, although Messrs. Bausch and Lomb finally consented to construct some prisms of a peculiar pattern, which were never used. In this dilemma we managed to secure the services of a competent lens grinder who was willing to devote his time on Sundays and holidays to us, and from whom Mr. Wappler acquired the art of grinding lenses and soon became far more adept than his instructor. Improvements were also made in the insulation of the lamp, so that in 1900 I was able to present before the American Association of Genitourinary Surgeons, in Washington, the first electrocystoscope manufactured in this country.

In the meantime certain instruments which I had ordered in Berlin, one of them having a calibre as large as 30 French, arrived, and although they were very beautiful in construction, and gave somewhat better results than the ordinary instruments, they failed entirely to secure the advance I had expected.

It then became apparent that the difficulty in securing a larger field was due to the presence of the prism in the ocular system, *which was apparently an essential portion of the apparatus.*

From the opening of the window, or upper face of the prism, the rays of light must always travel a distance within the prism equal to its depth, so that if the angle of the lens of the telescope is widened with a view to enlarging the field, this increase will unavoidably be cut off by the sides of the prism. In other words, if you attempt to increase the size of the field by increasing the angle of the lens you simply succeed in seeing the sides of the prism. Moreover, it is necessary to have the prism proportionally so large that the telescope can have but a small lumen, compared with the outside calibre of the instrument, and

thus a large quantity of valuable light is lost. The projecting edges and flat surface of the prism also form some hindrance to its easy introduction.

After many experiments and many failures this obstacle was finally overcome by *entirely eliminating the prism and substituting in its place a hemispherical lens*, the plane surface of which is silvered, a portion of the circumference filling and closing the window in the tube of the instrument as in the case of the prism.

A glance at the diagram will show that the substitution of this hemispherical lens is equivalent to the addition of two planoconvex lenses, one to the superior face of the prism which collects the rays at a wide angle and brings them together on the hypotenuse, the other on the anterior face of the prism which corresponds to the first lens in the telescope. It is not within

FIG. 1.—Hemispherical lens and the angle of its plane surface.

FIG. 2.—The Otis electrocystoscope, one half actual size.

the scope of this article to deal with the minute details of the optical apparatus, but the result of this manoeuvre proved eminently satisfactory, overcoming the objections pertaining to the use of the prism as a means of diverting the rays, enlarging the field, and increasing the illumination.

This instrument resembles in general the cystoscope of Nitze, but differs from it entirely in several most important features. It consists of two separate parts, the external catheter or sheath carrying the illumination, and the internal or telescope, in which the entire optical apparatus is contained.

The distal extremity of the external portion consists of a short beak (one half inch) set at an obtuse angle, containing the electric lamp in its tip. This lamp is of peculiar construction and deserves special consideration on account of its wonderful brilliancy and its almost entire freedom from heat. It is set so as to form the extreme end of the instrument; the light, unimpeded by any metal hood, illuminates the whole interior of the bladder. Its size is equal to the full external calibre of the instrument, and it is set in a metal socket or tip which screws in place after the manner of the lamp in the Nitze model, which a long experience has

demonstrated to my satisfaction to be more convenient when changing the lamp than the method of Leiter, also used in the French instrument.

One pole of the lamp is carried on the metal of the shaft itself, the other by a specially insulated wire, which does not encroach upon the internal calibre of the shaft and permits the use of a telescope several sizes of the French scale larger than that of other instruments, thus allowing the passage of a greater amount of light with a corresponding brilliancy of field.

(Note.—In order to appreciate the difference in insulation, it is necessary to know that a dissection of the Leiter instrument shows the insulation to be effected as follows: One pole of the lamp is carried on the metal of the shaft as before, then follows a thin tube of some insulating material, then a metal tube which carries the second pole of the lamp, another tube of insulating material, and again a metal tube to finish off the interior, so that we find an external calibre of 23 F. with a telescope of only 17 F.)

The shaft has a working distance of eight inches (i. e., from the centre of the window to the apex of the ocular funnel) and in the commercial instrument a calibre of 20 F. (three sizes smaller than the ordinary cystoscope). At the angle where it is joined by the beak on its superior surface, an oval window is cut through the metal to expose the lens of the telescope when in place.

On the superior surface of the proximal end is a short screw, at right angles to the shaft, on top of which a small ball is fixed, which indicates the position of the beak when the latter is in the bladder. A thumb nut on this screw serves to clamp the telescope firmly in position. On the inferior surface of the proximal end of the shaft is a metal post with an insulated core, which carries the electric terminals of the lamp and connects with the cords from the battery by a screw socket. A turn of this screw permits the lamp to be lit or extinguished at the will of the operator. For the sake of simplicity, this post has been made immovable and not working in a collar as in some instruments. Small stopcocks communicating with the internal calibre of the shaft have been placed just above the post, for the introduction of air, when it is considered desirable to use air instead of water as an examining medium.

The telescope contains the entire ocular apparatus and fits easily in the sheath. On the superior surface of its distal end is a window, cut in the form of the upper opening in a whistle, in which is set the hemispherical lens.

The proximal end consists of a funnel eyepiece with a movable metal collar at its apex, to which is fastened a small flat fork or crotch, the prongs of which pass on either side of the screw on the shaft, and serve to clamp the telescope firmly to the sheath with the thumb nut, at the same time allowing the telescope to turn on its own axis. A partial rotation of the telescope in this collar causes the lens at the end to slide from the window of the sheath, the opening then being filled by the back of the telescope, the lens facing the back of the sheath. In this way the cystoscope is introduced into the bladder, the lens being entirely protected from any contact with blood, pus,

or lubricant, which is most desirable when using a fluid medium and absolutely essential when air is employed.

After the instrument is well in the bladder the lens is brought into the window by rotating the telescope, a small knob on the ocular funnel indicating its correct position. Should the fluid in the bladder become clouded at any time on account of bleeding or the presence of pus, it is only necessary to remove the telescope, the sheath acting as a large catheter which permits the rapid withdrawal of the fluid contents of the bladder, which can be refilled, the telescope replaced, and the examination continued with but little loss of time and without removing the instrument, a much more effective method than that employed in the so called irrigation cystoscopes, all of which are necessarily feeble and ineffective.

To give a technical description of this instrument without becoming prolix and entering into tedious and uninteresting detail, is exceedingly difficult, and as it is the practical advantages which interest most surgeons I shall enumerate these as they occur in this cystoscope:

FIG. 3.—The outer circle (A) represents the field of the author's instrument at a distance of one and a half inches from the bladder wall, the inner circle (B) the field of the Nitze instrument at the same distance.

A field having an area four times as large as that of any other rectangular cystoscope, so that it is practically impossible to overlook any pathological condition in the bladder which might easily escape the smaller field of other instruments. Not only is this accomplished without loss of definition, but the field of this new instrument is rendered clearer and brighter, on account of the more powerful illumination of its lamp, the greater calibre of the telescopic tube, and the arrangement of the lens system.

After an extended practical experience with the cystoscopes of European manufacture, I do not hesitate to say that the field in none of them compares in distinctness and brilliancy with the picture as seen through this cystoscope, which cov-

ers a four times greater area. Nor have they the penetrative power or the ability to see distinctly at a distance from the object, as no matter how much the bladder may be distended, a clear image may be obtained with this instrument from any part of its interior.

Without referring to the optical formulæ by means of which these comparative areas have been arrived at, the size of the fields in the illustration (Fig. 3) were obtained by the commonplace method of clamping the instruments at a given distance from a highly illuminated sheet of paper and beginning at the extreme upper edge of the field, as seen looking through the telescope, drawing a line through the centre, from a point where a pen first came into view to a point just opposite in the circle where the pen point disappeared; the resulting line being used as the diameter of a circle representing the field of the instrument.

The instruments used for comparison were made in Berlin, Vienna, and Paris, and were found to be practically alike in area.

The arrangement and quality of the lamp and the large calibre of the telescope, rendered possible by the special device for insulating the second pole of the lamp and the elimination of the prism, give an illumination of field better than that in other cystoscopes, on the principle that more light will pass through a large tube than a small one.

The lamp has such a low ampérage that it emits very little heat so that it is practically impossible to scorch or, as has happened, seriously burn the bladder wall.

This cool, powerful lamp, together with the protection of the lens from being smeared during introduction, permits the use of air as the examining medium when this is considered advisable.

The short beak and absence of the flat top and sharp angular sides of the prism render it easy of introduction and less liable to cause bleeding.

Should the medium in the bladder become clouded, it may be rapidly withdrawn and replaced without removing the instrument.

Moreover the exquisite workmanship displayed in the construction of this instrument certainly appeals forcibly to me, and will challenge comparison with foreign cystoscopes of the first class, while Mr. Wappler assures me that it can be manufactured at a moderate cost.

5 WEST FIFTIETH STREET.

Civil Service Examinations for the New York State and County Service.—The New York State Civil Service Commission announces general examinations to be held April 8, 1905, including the following positions, for which application must be made on or before April 3rd: Assistant in clinical laboratory, Pathological Institute; pupil nurse, Erie County Hospital; physician, fourth and sixth grades, State hospitals and institutions, regular and homœopathic schools; woman physician, homœopathic school. Full particulars of the examinations and blank applications may be obtained by addressing the Chief Examiner of the Commission at Albany.

THE TREATMENT OF ACUTE TUBERCULOUS SPONDYLITIS IN INFANTS AND YOUNG CHILDREN.

By DEXTER D. ASHLEY, M. D.,

NEW YORK.

Physicians with clinical experience in the treatment of tuberculous spondylitis occurring in children from one to five years of age have frequently been disappointed in the results obtained with the generally used plaster of Paris jacket or variously modified brace. The child at this age is frequently so short and fleshy, and the pelvis so small, that it is difficult to adjust a brace so as to hold the diseased spine from progressive deformity.

In this country during the last twenty-five years, the so called "American, or ambulatory, treatment," which permits the child to be on his feet, facilitating exercise in the fresh air and sunshine with the idea of promoting digestion, has been held to be of such paramount importance that any device for the treatment of this disease which necessitates the recumbent posture has not met with general approval by the profession. In conservative Europe, where the pendulum of any movement does not swing so fast or so far, we find the old treatment by confinement still in vogue, though seldom in a manner to be commended.

Those members of our profession who are making a special study of tuberculous affections, have demonstrated by a long series of cases that such patients are benefited by limiting the amount of exercise to the minimum, while paying due regard to fresh air and easily digested and nutritious food. All admit that acute tuberculosis in any form is a disease in which the maintenance of the nutrition of the body is of primary importance, while exercise to the point of fatigue is found to produce a loss of weight and an abnormal increase of temperature. (See Report of the New York Academy of Medicine, February 5, 1903.)

We have several devices, each having its peculiar advantage, for treatment of spondylitis in horizontal confinement, such as the Sayre cuirass, the Phelps pappoose bed, the Bradford frame, the Lorenz plaster of Paris bed, etc., etc. Of all of these, the lightest, most cleanly, and efficient according to my judgment, is the modified Bradford frame, suggested by Dr. Royal Whitman. These modifications both in form and in use are so numerous as to amount to a distinct instrument, and I think it should be called the Whitman frame. For the benefit of those who are not acquainted with this frame, I shall give a description of it in this paper.

In 1900 it was my privilege to have under observation 127 cases of tuberculous spondylitis in

patients from one to five years of age, most of these with Dr. Royal Whitman in the out patient department of the Hospital for the Ruptured and Crippled. A study was carried out with the idea of ascertaining the relative benefit to be derived by these young patients from treatment by confinement upon the frame, the spine in superextension,

FIG. 1.—Steel or gas pipe frame with transverse bar to give rigidity.

compared with the ambulatory treatment in the plaster of Paris jacket. My departure from Europe in the early part of 1901 prevented the completion of my study in this direction. Dr. Whitman gave the results of his observations to the American Orthopædic Association at Buffalo in June, 1901, and these are recorded in the transactions of the association, Vol. 14.

About fifty of these patients were treated upon Whitman's frame. This frame is made of steel or gas pipe covered with heavy canvas, with lacings behind and canvas straps at the ends, which draw the cover tightly over the iron frame, making a firm support. It is made about three inches longer than the patient, and corresponds in width with the distance between the extreme ends of the coracoid processes, so that the ordinary child's frame is

was tops made for each frame, that one may be removed and cleansed. At the point of the kyphosis strips of saddle felt are usually so adjusted as to make pressure upon the transverse processes, and the frame is bent backward, moderately superextending the spine of the child lying upon it. This superextension is gradually increased, with an idea of separating the diseased surfaces in the bodies of the vertebrae by *gravity traction* of the parts below and above the diseased area, thereby facilitating repair and differing, I believe, in this respect, from any other plan of treatment in horizontal fixation in use in this country.

To secure rigidity, Dr. Whitman wraps bandages around the frame, under the position of the trunk, before applying the canvas cover. I have found it possible to secure greater rigidity by the introduction of a light, transverse steel bar at the point of the kyphosis, with a convexity backward,

FIG. 3.—Anterior view of covered frame, showing apron and oil-cloth under region of buttocks.

FIG. 2.—Posterior view of covered frame, showing transverse bar, apron, manner of lacing, etc.

from 33 to 38 inches long, from $5\frac{1}{2}$ to 7 inches wide, and weighs from $3\frac{1}{2}$ to $4\frac{1}{2}$ pounds. Rubber sheeting is sewed to the canvas in the position of the buttocks, and the child is secured to the frame by an apron extending from the top of the sternum to the symphysis pubis. It is well to have two can-

so that it will not come in contact with the top canvas. (See Figs. 1, 2, and 3.)

The results in the main were satisfactory in these fifty selected cases under observation on the frame. The kyphoses became less prominent, the spasms were markedly lessened or entirely subsided. The children's growth, which is so frequently impaired in this disease, proceeded normally. Their general appearance and weight were improved. The thorax was frequently, in very young children, apparently flattened anteroposteriorly, which is not an undesirable result, since, as Dr. Whitman remarks, "it is quite the reverse of the natural tendency of the deformity."

The following disadvantages are apparent:

First, treatment by this method necessitates frequent supervision by the surgeon. At least once in two weeks the patient must be seen for the adjustment of pressure pads, increase or decrease of superextension, and, most important of all, for the

supervision and instruction of the mother or nurse in the handling of the child, since it is desirable to remove the patient from the brace every day, to lay him on a pillow face downward, the back being rubbed with pure alcohol, and powdered. This handling of the child by the mother jeopardizes the advantages of this treatment, the mother failing fully to comply with the instructions, through lack of comprehension, neglect, or oversympathy for the child, thus laying this treatment open to the common criticism of any brace that is removable by the parent.

Second, the lateral motion of the spine is only imperfectly restrained.

Third, the motion of flexion at the time of changing of soiled clothing, with consequent irritation of the diseased spine, can hardly be avoided.

Fourth, patients having extensive deformity find the gravity traction exceedingly painful, if not intolerable.

During the past year I have had several very acute cases of tuberculous spondylitis, which in spite of my best efforts with the Whitman frame alone, continued to have abdominal and thoracic spasms, these spasms being apparently increased in frequency and severity during the effort to superextend the spine by gradually bending the frame. I attributed this failure to obtain beneficial results largely to the fact that the parents had not the fortitude to keep the child upon the frame until the spasm of the muscles had been overcome by the gravity traction, and farther, that the kyphosis was so sharp in some cases that the spinal muscles in spasm preventing superextension really increased the pressure upon the diseased surfaces of the vertebrae.

With an idea of relieving this spasm, and encouraged by the testimony of Robert Jones, of Liverpool,¹ and J. R. Goldthwaite,² of Boston, I gave the patient an anæsthetic (although this is not always necessary) and submitted him to a modified Calot operation.

I do not intend here to advocate the universal resort to the modified Calot for the reduction of the kyphosis in tuberculous spondylitis. My experience has been too limited to give conclusive data. Mr. Jones had reported 83 operations in 1902, in patients from 18 months to 22 years of age. He has modified Thomas's hip splint, and uses it to secure immobilization in the superextended position. He uses no plaster of Paris. Mr. Jones is inclined to approach the original Calot, sometimes operating upon extensive and long stand-

ing deformities. According to his judgment, kyphoses reducible by this method are: those occurring in the young, those in which active disease is present, and those in which the angle of deformity is changing.

Dr. Goldthwaite, as I understand it, uses the gravity traction for the reduction of the deformity, at the time of the application of the plaster of Paris jacket, and is then content with the ambulatory method.

The method which I have employed in treating these young children differs in some particulars from any procedure heretofore described.

The child is supported face downward in the horizontal position, the body at right angles to a table, the upper third of the thighs resting near

FIG. 4.—Position of patient in extension and counterextension during application of plaster. (Note position of operator's hands making pressure just as plaster hardens.)

the edge of the table. Extension is made upon the head and arms, the arms at right angle to the body, and counterextension upon the feet, always sufficient to overcome any sagging of the body in lordosis. The kyphosis is gently pressed down until nearly or quite obliterated, no considerable force being employed. (See Fig. 4.)

The child is held in this superextended position while a snugly fitting stockinet shirt is applied over a rubbing bandage. Over this is adjusted a felt pad about three inches wide, extending the length of the spine, and felt pads cover the anterior superior spines. These are secured by one layer of sheet wadding bandage, and over all is applied a light, closely fitting plaster of Paris jacket, extending from the top of the sternum to the symphysis pubis. The spine is held in superextension until the setting of the plaster, by one hand pressing down upon the region of the kyphosis, and the other pressing upward upon the upper part of the sternum, slightly flattening the thorax, if anything. I prefer this method to suspension in applying jackets to children, it being less harrowing to parents and

¹ The Immediate Obliteration of the Deformity in Pott's Disease.

² The Immediate Correction of the Deformity Resulting from Pott's Disease.

patient, and the movements of the child being more easily controlled.

The patient is then transferred to a Whitman frame, which is bent to conform to the plaster. The cast is trimmed like an ordinary jacket, except that it is left longer than usual in front, there being no

and adjusted well to the occiput, the neck being moderately superextended, and the head secured in this position by a coronal band. The plaster is then cut out, exposing the top of the head, the face, and the ears.

The patients are confined upon the frame for from six to eight months, after which they are permitted to assume a semisitting position by elevating the head of the frame. The plaster is changed at intervals of from three to four months, the skin being kept clean in the mean time by the rubbing cloth.

If on changing the plaster a distinct spasm of the muscles of the back is found, which would indicate the continuance of the acute stage, it is best to continue the gravity traction. We are apt to err in the direction of too short confinement rather than too long. If the kyphosis was large, and considerable

FIG. 5.—Position upon frame in gravity traction, showing abdominal fenestra, the stocknet rolled up on corset at upper end.

intention that the child shall assume the sitting position. After the jacket is well hardened, usually on the day following its application, an oblong fenestra is cut out in front, extending from the centre of the gladiolus to from $1\frac{1}{2}$ to 2 inches below the umbilicus. In case any considerable kyphosis has been reduced, a small fenestra is cut out at the back over the knuckle, this cutting being facilitated by the one layer of cotton. (See Figs. 5, 6, and 7.)

The child is confined to the frame by the usual

FIG. 7.—Child with paraplegia due to cervical spondylitis, with head in superextension, immobilization, and gravity traction.

FIG. 6.—Stocknet everted, covering fenestra.

apron. If the point of disease is in the lumbar or lower dorsal region, one or both limbs are included by a short spica in order to secure immobilization of the diseased part. (See Fig. 8.) If high dorsal or cervical, the plaster is extended to the head,

force was used at the time of operation, a longer period of fixation in recumbency is necessary than if the kyphosis was small and little force was employed.

In one case a psoas abscess presented in four months after the operation, which so far as I could discover had no relation to that procedure. There being no constitutional symptoms, it was permitted to gravitate downward, somewhat below Poupart's ligament. Later there appeared signs of spontaneous evacuation in the inguinal region. To prevent this an incision was made some two inches below and external to the anterior superior spine, through the fascia lata, and upward and inward through the healthy tissue to the site of the abscess, which was thoroughly drained, flushed, and gently wiped out, after which strong compression was made over its lower course, and the incision sewed up to prevent mixed infection. Much to my satisfaction, after eighteen months no reappearance has

occurred. If it should do so, I should again evacuate and sew up.

If the jacket is properly applied, the flexion deformity having been reduced and the spine placed

FIG. 8.—Lumbar Pott's as treated by Vulpius. Picture taken in Heidelberg.

in superextension with a felt pad extending the entire length of the spine, there should be relief from pain. I have found that there was some fault in my technique when this condition was not attained, and have always reapplied my jacket if the pains did not subside within a short time. The apparently prevailing idea that a plaster of paris jacket may be applied by any one is fallacious. In my work, while exercising the greatest care in application, I find that each jacket varies in efficiency of support, as proved by the comfort or discomfort of the child, by the prevention or correction of the deformity, or the permission of greater deformity. A jacket may be applied smoothly, and yet be entirely inefficient, or even injurious. It is not enough to wind a plaster bandage upon a deformity. With no more skill the variously modified brace is frequently bent to conform to the deformity which it is supposed to arrest or support. The spine should be placed in a position tending to correction, and the jacket so adjusted as to maintain that position. Only a minute knowledge and attention to detail can bring these patients through their disease without a hideous deformity. The time should be past when the general practitioner will essay to apply a plaster of paris jacket by the aid of a nurse and swing borrowed from an instrument maker, to the inevitable detriment of the patient. With quite as much reason might the same general practitioner, without special surgical preparation, attempt an operation for appendicitis.

Patients confined upon the Whitman frame should have careful attention to prevent any disturbance of digestion. The child must have the advantages of fresh air and sunshine. These may be obtained even in the crowded districts by the utilization of the fire escape or the house top. Even

the street is better than a dark room. The frame should be adjusted to a baby carriage, and the child kept in the fresh air all day in pleasant weather.

The diet should be confined to nutritious and easily digested food, consisting especially of raw milk, fresh eggs, raw, rare or partially cooked beef well salted, oysters, clams, breakfast food with plenty of milk and cream, stale bread with plenty of butter or olive oil, potatoes sparingly and only boiled or baked, plenty of fresh, succulent vegetables such as string beans, peas, and cauliflower. Baked apples and stewed prunes may be given, and oranges and bananas sparingly. The diet may be varied along these lines.

I cannot urge too strongly the advantage of the use of appropriate fats in the diet of these cases. For this purpose the forced milk feeding, combined with cod liver oil emulsion, is to be highly recommended. In this combination, it will be well to administer castor oil daily, sufficient to induce two copious stools, and small doses of calomel (from one tenth to one fourth of a grain) with soda, every week or ten days, followed by oil, or citrate of magnesia, with occasional flushing of the colon with warm soapy water. Digestion may be further aided by administering light massage to the abdomen through the fenestra. Above all, give the child plenty of water to drink.

To aid constructive metamorphosis, I occasionally advise the administration of the triple phosphates, the syrup of the iodide of iron, beef, wine, and iron, and other forms of iron, especially for anæmic patients. The chief dependence, however,

FIG. 9.—DR. E. B. Young's device for measuring the antero-posterior deformity.

should be placed upon fresh air, diet, and immobilization in superextension.

I have never found it necessary to use opium in any form for abdominal spasms, and think that its use is to be condemned.

One of the most important considerations in caring for a patient suffering with this disease, in order

to judge the efficacy of the treatment, is the making of accurate tracings at regular intervals, and recording the same so that they may be carefully compared. I have found that the generally used lead tape is so easily bent while lifting it from the child's back to the tracing paper, that one may be deceived by his own tracing. I have been using for five years the device invented by Dr. E. B. Young, of Boston. (See Fig. 9.) This is better than the lead tape, and has the advantage that it may be quickly adjusted to the deformity. Mistakes may be made with this instrument, however, in tracing the irregular slots' surface. With a docile patient, the most accurate measure may be obtained by the use of the plaster

FIG. 10.—Tracings showing deformity, and after-tracings for two years, showing correction and growth of patient: A, March, 1903; B, June, 1903; C, July, 1904; D, February, 1905.

of paris bandage. To secure uniformity of posture at the time of measurement, place the patient in the prone position, upon a firm, flat surface, arms at right angles to the body, hands under the forehead. Smear the surface to be covered with glycerin, thus preventing the adhesion of the plaster. This may be easily removed by warm water, being superior in this respect to vaseline. Apply the bandage over the spinous processes from the occiput to the dip of the sacrum, the bandage being folded upon itself and smoothed down neatly, and retained until the plaster is set. If S. S. White's quick setting dental plaster is used, this will take but a moment. If we use a three inch bandage, we shall have a record of the lateral curvature as well, which the other devices do not record. The dried strip, bearing the date and name, may be preserved, or cut or sawed down through the center at the point of touching the spines of the vertebrae, when from either half we may make an accurate tracing of the deformity in the record book. (See Fig. 10.)

In addition to the advantages obtained by the use of the Whitman frame, I claim the following advantages for the use of the plaster of paris jacket

and the modified Calot procedure in the cases under consideration:

First, the deformity and spasm are immediately overcome, and the spine is at once placed in the position which is most conducive to the healing process.

Second, the spine is securely held in this position, the pressure pads are adjusted by the surgeon, and remain in the desired relation.

Third, no lateral motion of the spine is permitted, nor any undue flattening of the pelvis.

Fourth, the necessary handling of the child is done with the least possible disturbance to the spine. The skin may be kept clean by means of the rubbing cloth.

Fifth, it conserves the labors of the surgeon and permits the treatment of patients from a distance, where frequent observation is impossible, it being sufficient after the treatment is well established, to see them once in from one to three months.

Sixth, by the modified Calot procedure we increase the capacity of the thorax, relieving pressure upon vital organs.

Seventh, paraplegia, with hardly an exception, becomes less or entirely disappears. Sometimes the improvement may be seen within a few hours.

Eighth, in marked deformity, where the angle of flexion is so great as to render the supine position almost intolerable, the reduction of the kyphosis makes this position at once comfortable.

It is quite evident that if we keep the spine from tipping forward above the point of disease until partial ankylosis has taken place, it will then be much easier to control the deformity otherwise caused by the dropping forward of the superincumbent portion of the body. After the pelvis has developed sufficiently to support a jacket, and when the absence of spasm of the muscles of the back indicates that the healing process is proceeding satisfactorily, the child may gradually assume the erect position with appropriate support.

337 LEXINGTON AVENUE.

Magazine Note.—The *Century* has in its April issue the first of two articles by Anita Newcomb McGee, M. D., on The American Nurses in Japan. Dr. McGee was acting assistant surgeon in the United States Army during the Spanish War, the Philippine insurrection, and the Boxer campaign, serving directly under Surgeon General Sternberg. At the head of a band of American Red Cross nurses, Dr. McGee worked for six months last year in the hospitals of Japan, services recognized by the Mikado and honored by the entire nation. Dr. McGee is the wife of Dr. W. J. McGee, the anthropologist and geologist, and daughter of Professor Simon Newcomb, United States Navy, retired, the eminent astronomer,

RECENT ADVANCES IN ELECTROTHERAPEUTICS.*

By WILLIAM JAMES MORTON, M. D.,

NEW YORK.

My first thought this year in attempting to portray for the third time before the association at our annual meeting, recent advances in electrotherapeutics, is, that in general, a great and almost revolutionary advance has recently been attained, by leaps and bounds, so to speak, in the domain of physics. This advance consists in the dethronement of the atom as an ultimate concept of our knowledge of small things. Ordinarily, the physician has not been expected to know much about general physics. His studies have been more particularly confined to botany, inclusive within recent years of bacteria, to chemistry, and to zoology. But to-day the importance of general physics with the medical man holds its own fairly with the importance of the special physics of chemistry, his principal physical pursuit up to the present time. The revolutionary advance in physics which I refer to, is, of course, familiar to you all in connection with the new theories of our conceptions of the constitution of matter, and so far as the science of medicine is concerned, this revolution redounds almost exclusively to the glory of electrotherapeutics, for it is precisely these new doctrines that have enlarged the possibility of the treatment of disease by agencies now admitted to be fundamentally electric, and yet how different to the electricity referred to in our older works of electrotherapeutic lore.

In general the trend of the new order of thought is somewhat as follows: It has long been an established doctrine that electricity exhibits energy under the form either of strain or of motion, affording in the former case an instance of "charge," and in the latter an instance of "current." But this does not define what electricity is. The new provisional thesis promulgated by Sir Oliver Lodge with his usual brilliancy is no more nor less than this, that matter itself consists of electricity, not of an ill defined, mysterious, pervasive, and subtle something, but of actual particles, corpuscles or electrons, capable in their grouping, of correlation to the well known laws of chemical affinity and of explaining the production of the radiation or vibrational phenomena like light and x radiations. According to Dr. Lodge, positive electricity exists as small particles, the size of an ordinary atom of mat-

ter. Negative electricity exists in still more minute particles termed electrons. Such an electron is a unit of electricity and not a material particle plus an electric charge. Each electron has a mass which is about $\frac{1}{800}$ of that of an atom of hydrogen. This fact, namely, that masses actually smaller than atoms exist, has been experimentally demonstrated by Professor J. J. Thompson. That, at least negative electricity, in its ultimate analysis, is a small charge or a small charged body, is now a doctrine definitely accepted. It would, for instance, require 800 hydrogen negative electrons to make up a mass weighing as much as an atom of hydrogen. Each substance known, however, has its own specific number and arrangement of electrons, and therefore, each kind of atom as at present conceived of in ordinary chemistry may hold a diverse number of these electrons. Uranium and radium, for instance, since they are very heavy chemical atoms may contain as many as 200,000 electrons. From these heavy atoms some electrons fly off and thus we have radioactivity as discovered by Becquerel and demonstrated by the Curies in the case of radium.

In the differing number of electrons to each chemical substance we have an exact correlation to the atomic weights. For if, quoting Lodge, a substance has twenty-three times as many electrons as hydrogen has, we call it sodium, and if it has two hundred times as many as hydrogen, we call it lead or mercury, and if it has still more it exhibits instability, and the substance exhibits what is termed radioactivity as in the instance of uranium and radium.

Corpuscles or electrons as described, may, on occasion, fly off at nearly the speed of light from the positive mass. Flying off from the negative terminal of a vacuum tube and striking a massive target (anticathode) they set up an ethereal pulsation which we call x rays, while equally owing to their smallness they themselves penetrate other forms of matter. Likewise, the same particles fly off from unstable elements like radium and by impingement upon each other set up again ethereal pulsations (gamma rays). Such radiations are of the same nature as light.

Metallic conduction is believed to be the permeation of these little particles through the substance of metallic conductors, each particle as Lodge describes it being handed on from one atom of the metal to the next. In liquid or electrolytic conduction, on the other hand, the particle and the atom travel on together and at the same rate of speed; by reason of the junction of the two, the speed of travel is slow. In rarefied

* Read before the annual meeting, American Therapeutic Society.

gases, on the other hand, the speed approaches that of light.

These opinions relating to our fundamental conceptions of the nature of matter and of electricity as composing matter, while astounding to physicists and in a sense tentative, reflect at the same time a new light and a new interest upon electrotherapeutics. For if matter may break up into corpuscles or electrons, which are particles of electricity, then also the same corpuscles or particles of electricity, must have once formed into matter. This leaves us in the position of claiming that electricity in one of its forms constitutes matter. If it should turn out that the material substance of our bodies, of our tissues, of our muscles, nerves, and glands, are of electric constitution, it follows according to the laws of action and reaction, that the extraneous and applied electricity common to electrotherapeutics must exert upon these tissues a most natural reaction and constitute at the same time a most natural, scientific, and explicable form of therapeutics.

We may roughly tabulate some of the new order of facts relating to radiations as follows:

RAY.	SOURCES.	THERAPEUTICAL EFFECTS.
Hertzian waves.....	Electrostatic.....	Physiological
Dark heat and u rays.....	Heated substances, etc.....	Physiological.
Radiant heat.....	Incandescence, etc.....	Physiological and inflammatory.
Visible spectrum.....	Arc lamp.....	Physiological and inflammatory.
Ultra violet.....	Arc lamp.....	Bactericidal, etc.
Alpha (emanations).....	Radium.....	Chemical, physiological, cal, bactericidal, inflammatory, electroscopie, photographic.
Beta (corpuscles).....		
Gamma (ether pulses).....		
Cathode rays.....	Crookes's tube.....	Chemical.
X rays.....	Crookes's tube.....	Chemical, electroscopie, bactericidal, physiological, inflammatory, photographic.

This new electrotherapeutics includes the application of radiations in medicine. The entire gamut of radiations is called upon, running from the longer Hertzian waves onward through the dark heat waves, the heat, ultra red, red, and visible spectrum rays, the ultra violet and to the x ray, and back of the radiations themselves, is the disintegration of the atom with its corpuscular bombardment of alpha and gamma rays, as demonstrable in the instance of radium and other allied substances.

We may also mention specifically the high potential, high frequency current, not only as a part of the above enumeration, but by itself, as being at the present moment a specially attractive method of procedure. We do this to point out that there is great danger of confusing a mere brush discharge with a true high frequency current. As first pointed out by myself in 1881 and 1891, the true high frequency current is to be derived from what I named at that time the static

induced current, a terminology admitted to-day by highest authority to be accurately descriptive of the phenomena involved. There is a tendency at the present time to sacrifice to the more spectacular effluve or brush discharge the true physiological effects which really only belong to the real high frequency, high potential current, or, if we prefer the term, to the static induced current.

In connection with the high frequency current referred to, Sir Oliver Lodge, in a recent lecture to physicians, speaks as follows: "Very small electric oscillations can be made to run to 50 millions a second. The Leyden jars we shall have next time will give a frequency of 30 to 100 millions." In this connection, I may be pardoned if I point out that in 1891, long before the distinguished physicists, Tesla or d'Arsonval, had written a word upon this subject of oscillatory discharges, I used the following language: that "computing the spark interruption to be at least two hundred a second and the oscillations of each spark to be one hundred millions a second, we have a current giving twenty billion alternations a second (remarking at the same time, in regard to the nature of the physiological results produced, that 'in the great rapidity of the alternating (oscillating) currents of the spark discharge, particularly in the rapid series . . . we find the reason despite smallness in the quantity, for accomplishing work in producing nerve and muscle stimulation. . . . The conditions may be compared to a bullet shot from a rifle, or the same bullet gently rolled across the floor.'" ¹

Dr. Lodge also points out that "the brush discharge is often spoken of as the high frequency current, though it is often not of a high frequency at all." It is evident many solenoids now in such common use in connection with my original high potential, high frequency current called the static induced current, must act as "choke coils," and serve to dampen out the oscillations or frequency. Many of our recent and modern high frequency apparatus could more properly be called *potential raisers*.

The recent advances in the use of the high frequency currents appertain mostly to the very greatly increased use of these currents, and to an attempt to decide upon their effects in the treatment of disease. In the main the early contentions of myself and of d'Arsonval as to these physiological effects have been sustained. Dr. Chisholm Williams, of England, has applied high frequency currents with great benefit in the treatment of tuberculosis and is continuing his stud-

¹ Medical Record, January 24, 1901.

ies along that and other lines. Dr. Horace Manders is also carefully investigating the high frequency treatment, as are many others in England, in our country, and elsewhere.

So far as apparatus goes, the writer has published an account of his new solenoid-condensor-resonator. (*Second Report of the Committee on Current Classification and Nomenclature*, American Therapeutic Association, September 24, 1903.)

Röntgen Ray.—It would be interesting to review the historical growth of radiations in their relation to medical practice. Suffice it to say that the Röntgen ray was the first to be used in electrotherapeutics, and the experience thus gained most naturally led to the use of radium in the same manner.

Of the continued use of the x ray in the treatment of cancer and of lupus, it can, in the opinion of the writer, be very truly said that the x ray has considerably increased the percentage of cure in cancer. The cure of the rodent ulcer is generally admitted. Similarly, some cases of deeper epithelioma and of carcinoma of the breast can be cured by the x ray, when it is doubtful if this could be done by excision. As to deeply seated cancer of internal organs, it cannot be said that much can be accomplished. But if a carcinoma of the stomach is of a superficial type there is little doubt but that some cases are cured. The same statement holds true also of some cases in the upper air passage. Some cases also of cancer of the uterus have been cured and many retarded in their progress.

Dr. Leopold Freund has published a classical work upon radiography, bringing the subject up to date, while Dr. Carl Beck in our country, has embodied his own brilliant original work in a volume of great value. To Dr. Beck radiography in its applications to surgical diagnosis owes much of present high position.

Radium.—The use of radium from a therapeutic standpoint has been most interesting, and an entirely complete method of procedure has not yet been agreed upon. The first applications were of radium salts in glass tubes, but it was quickly pointed out that only the gamma rays, which resemble Röntgen rays, could escape through the glass. Aluminum tubes were then substituted. These allow of the escape of the beta rays, corresponding to the cathode rays, and greater effects were produced. But perhaps about ninety-five per cent. of the corpuscular projection of radium consists of alpha rays, which are positively charged atoms of electricity and possess little penetrating power. In fact, these alpha rays behave as do gases, and may be col-

lected in receptacles, or become attached to other substances, and may also in their turn give forth radiations. This quickly suggested the capture of these gases in solution in fluids, and led to the use of radioactive water. It has often been denied that water can be rendered radioactive, but in some tests which Professor Pegram and Professor Halleck, of Columbia University, were kind enough to make for me of some water which I had prepared, it was perfectly evident that the water was strongly radioactive. The radioactivity of the water, according to Professor Pegram's data, kindly secured for me at my request, was about one half that of uranium oxide.

Radium exerts, as does the x ray, a decided effect in retarding growth in some cases and some stages of cancer. But while neither the x ray nor radium comes up to the extravagant expectations of cure early entertained, it must nevertheless be generally conceded:

1. That both have increased the percentage of possible cure of cancer, and
2. As an outcome of their success, all cases will be treated in any event by radiation after operation.
3. Or that, as I have always advocated, a combined or composite plan of treatment will be adopted, in accordance with which the patient will be treated by the x ray or by radium, both *before and after* a possible operation.

Artificial Fluorescence of Living Tissue.—Among the recent advances in electrotherapeutics, I may mention the plan proposed by myself of saturating the living human body with harmless fluorescent substances, like quinine, fluorescin, eosin, etc., and then subjecting the body thus saturated, to the x ray or to radium, whereupon these fluorescent substances are excited to give off their characteristic fluorescent light. We thus treat the patient, or some part of the patient, or any part of the patient desired, with *interior light*. This method means that light is developed within the very tissues themselves in among the cells and fibres and cavities, and there effects its specific result. Whatever has been found to be true in greater or lesser degree in phototherapy of the external applications of light is here produced internally, and in intimate relation to parts, like the liver, spleen, lungs, etc., to which light has not hitherto been caused to penetrate. In such a combined treatment the x radiation and the radium radiations lose their identity, because they become absorbed in the act of producing fluorescence. The x ray and the radium are merely exciting causes, while the effective agency is the light.

This treatment is giving excellent results in my hands, and has been followed by others very successfully. I am happy to note that my idea has been adapted to the purpose of illuminating the cavity of the stomach, by filling this organ with an innocent fluorescent fluid, and then swallowing the usual stomach lamp.

Among substances which give fluorescence to light are quinine, æsculin, rhodamin, eosin, petroleum jelly, or vaseline, petroleum in general, paraffin, tumeric indigo, stramonium, naphthalin red, litmus, henbane, gentian, fluorescent copper, potassium chromate, fluorescent cochineal, etc. I have found by experiment, however, that some of these substances which are beautifully fluorescent to light, are not correspondingly fluorescent to the x ray and radium, while on the other hand, substances which are not fluorescent to light are highly fluorescent to the x ray and radium. For instance, benzoate of sodium is fluorescent to the x ray and not fluorescent to light. Among fluorescent substances, there is one I have lately discovered, which I believed to be æsculin of silica. Certain it is that a sodium glass test tube in which æsculin in solution has been retained for one or two weeks produces a shadow picture upon a photographic plate quite equal to that produced by a quarter of an inch of lead. It would seem here as if a new law of Röntgen skiagraphy could be expressed in these terms, namely, that contour shadows may be caused upon photographic plates due to fluorescent absorption, rather than to the arrest of the x ray by the density of the intervening material. Many other experiments prove beyond question that this law holds good of fluorescent substances at least in their dry state and probably also in liquid form.

My principal therapeutical treatments have been with quinine, æsculin, and fluorescein. Fluorescein is particularly desirable on account of its non-toxic properties.

The special application that I am now making of this method is in tuberculosis, in the treatment of lupus, of tuberculous glands, or other tuberculous deposits. My cases of lupus are now healing with greater rapidity than I have ever seen before, and my cases of tuberculous glands get well quicker than before. Cases of tuberculous lungs are making really remarkable progress with diminution of cough, cessation of night sweats, gain in flesh, diminution of the bacilli discovered in sputa, etc. I expect at an early date to make a specific report of these cases.

Cases of chronic malaria under this treatment, under the use of fluorescein and not quinine, have recovered. In a recent case of *amœba coli* in which

two abscesses had been opened and in which to stem the progress of disease, it had been proposed to open the colon and to inject ice water, the parasites have been absolutely destroyed. This case was recently reported by Dr. Stieglitz. (N. B. Subsequently, however, a relapse occurred.)

On the whole, the prospects for this new method seem to be most brilliant and we may note a distinct advance, namely, an advance where light is developed in the interior of the body instead of as previously, from the exterior.

The method of the production of light in the interior of tissues possesses two practical applications, which may in conclusion be mentioned here.

If we administer to a patient twenty drops of an aqueous solution of fluorescein, one part of fluorescein to thirty of water, and, say, forty minutes later on make an x ray exposure to a photographic plate, we obtain a radiograph of superior contrast and definition. In a similar manner, fluorescopic examination of this patient, particularly of the thorax in tuberculosis of the lungs, is greatly aided.

An advance which should not pass without notice here has been made by Professor Stephan Leduc, of Nantes, France, who has shown in the most scientific and conclusive manner that a profound general insensibility to pain, namely, general anæsthesia, may be produced by electricity alone and safely also, that is to say, that the animals experimented upon come out from the anæsthetic state without any impairment of their functions. Dr. Leduc employs the usual battery currents, namely, currents of low voltage and high current strength, interrupted slowly. Prior to falling into the anæsthetical sleep, animals experience a series of epileptiform and convulsive seizures, which soon cease. It yet remains to apply this practice successfully to general anæsthesia in human beings, but the possibility remains that this may be done. Dr. Leduc's contribution to the subject is certainly one of the remarkable features of the year's progress.

19 EAST TWENTY-EIGHTH STREET.

Measles in Albany.—Albany is in the midst of an epidemic of measles, and there are scores of cases. It is not confined to any one section of the city, but is widespread. Up to the present time there have been no deaths from the disease, and it is probably not as bad as it is in some other sections of the State. There are said to be 500 cases besides 330 in the adjoining city of Troy.

TWO DIPSO MANIACS; ILLUSTRATING
TWO DIPSO MANIAC PHASES.By T. H. EVANS, M. D.,
PHILADELPHIA.

The difference between voluntary and involuntary drunken habits is the difference between simple inebriety and dipsomania. The latter is a condition growing out of some fundamental taint which expresses itself as a neurotic explosion of a peculiar character, namely, an overpowering desire to numb consciousness with the poison of alcohol, which, when arrived at, produces fear and disgust in the patient for his achievement. The attack in the end clears the sky and the storm sweeps out the toxins and waste products, with the patient to start again free, for a time, of the shadow that had intensified up to the attack.

The variations in temperament and effect are as many as the cases, so that each one is to be studied as a distinctly personal manifestation. William Lee Howard (1) suggests that many patients are of intelligence and social position; meaning, I suppose, the same as has been said, that it "takes brains to go mad." I am not ready to admit that cases cannot appear among the ignorant and originally degraded. However, with their lack of incentive and self respect the malady will not present itself in a typical light, since it is the despairing struggle of the patient that gives the picture its Dantean effect of misery and remorse; the suffering of the patient's friends is equalled only by their obtuseness to the nature of his shortcomings.

Why they continue to preach to him, to threaten him, to have him arrested, as wives do, in the daily sittings of the police court, I realize, but hope for better when the lay community is instructed as it should be. The efforts of prohibitionists fail utterly to impress a scientific and satisfactory meaning on the public. School textbooks omit important facts, in an anxiety to explain to the children the secrets of hob nail liver, cirrhotic kidney, etc. In school the useful is often replaced by the ornamental and curious; there is little time to teach the dignity of work, the value of money, the need of asking for receipts for money paid, and countless other essential things; they are taught not to know things, but only to know about them. This is bringing up the child in the way he is not to go. The defect in the public school system is the attempt to force children of divergent personality along identical paths. Little reference is held to physical or mental peculiarities, temperament, heredity, or physical adaptability; e. g., all human beings are

certainly not fitted for doing eye work, but civilization has set us all at the task. Hence, eye strain is present and real enough even if it is not just the factor some writers assert.

Backward and truant children are, perhaps, more sinned against than sinning. I think their rights of choice are to be regarded, as well as their physical and mental competency, instead of practically throwing them under the Juggernaut of education.

A survival of the idea of children inheriting the social rank of their parents crops out in efforts to educate all our children up to or above the parental standard. Plato's "iron men, silver men, and gold men" is not to be overlooked in this connection. Specialization and division of labor should make an honorable place for men of all grades of intelligence and capability. But we are mistaken in thinking education, at least of a fixed type, is a panacea for the ills of civilization; or that it is the process of running all children through the same mould to that end. Such and other similar mistaken attempts in cases of neurotic or degenerate temperament is largely at the root of the increase of morbid processes among which to-day dipsomania is prominent.

CASE I.—Mr. John D., aged 47 years. Born near Glasgow, Scotland; married, having four children.

Is a weaver and expert at his trade. From youth has always been considered of good intelligence; he is well read and discusses questions with an unusually broad viewpoint and native logic. His father was wealthy, as wealth goes in the country districts of North Scotland. The boy grew up surrounded by the best moral, social, and intellectual influences. His mother died in his youth, and a second marriage introduced a disturbing factor in the home. He has the belief that his efforts were never valued as those of his brother; to a sensitive and bright child this was disheartening. At school and in play the unequal rivalry was continued with the result of unhappiness and disagreement.

He does not remember just how the drink habit fastened itself, for liquor was not forbidden as he grew up and the tendency came gradually. After awhile frequent indiscretions made it necessary for him to leave the father's employ, bringing his family with him to America.

Here, at first, things went better. He came under the influence of the settlement work of the sister of Dr. Kelly, of Baltimore. This noble woman devotes the best part of her time in Philadelphia to the Kensington mill district, where every effort is made to improve the living conditions and add to the morals and happiness of the workers.

For a year Mr. D. was a leader in prayer meetings, and a steady enough fellow. This was but a glimpse of better things.

Again and again he had to fight off tempta-

tion, finally to sink; and in shame he left America. He could not do better on his return to Scotland, and leaving his family there he returned to Philadelphia. They have since come over to him and he is making the fight again. Within a few months he has sworn off twice, and twice I have heard that he has taken clothing out of the house to pawn for drink. His wife has a slight income and his father sees that they do not absolutely want, but his home is a four room building on a small street, and destitute of the refinements to which he and his wife were originally accustomed, and a sad commentary on the effects of what is not a depravity, but a disease, and which is only to be controlled when so recognized.

He has been twice in jail, an event pernicious to all self respect; but his wife could not control him in the house. Twice has he been in the county hospital, whence he was dismissed after the four or five days in which his state of alcoholism subsided. Now, why was he not detained in the wards provided for mental affections; could it not be seen that this was no ordinary alcoholic case? Simply because the county must be saved expense, and patients are not looked upon as souls struggling in torment so much as wretches who may as well have their course to run, in the end to add to the supply of hob nailed livers and sclerosed stomachs in the museum jars. As a matter of fact money could be saved to the community in properly caring for its dipsomaniac cases.

His appearance, now, is that of a neurasthenic and broken spirited individual. He speaks in a high pitched drawl which tells of depression and the shame of defeat as borne in upon what was a mind of no common intelligence. His complexion is sallow. He is about 5 feet, 8 inches in height, large boned, nearly brachycephalic, uncertain in mandible, with shifting glance of eye and nervous walk. Altogether a pathetic specimen. Even under the influence of alcohol his apologetic manner is preserved.

A defect in the right eye and anisometric astigmatism add to the elements against which he has had to make his fight. He is a good workman, and when he works steadily seems better able to resist the desire for alcoholic intoxication. Three times I have seen him in the paroxysms.

I have sat up with him through the night. While his wife lay ill with erysipelas, I have kept him from stealing the clothing and furniture from the house. I have suggested to him, I have threatened him, I have argued with him, "hyoscined" him, fed him, and travelled with him.

The cry is "just one more drink, just one; then I will never touch it again." It is no use to believe him. He has been in my office, and gone straightway out to a saloon after telling me how well and strong he felt and how determined to put it out of his thought.

I discourage his talk of the matter. I believe a certain despair compels these people to assure themselves and others that they will leave it alone, comparable to a man's trying to lift himself into the air.

He calls himself a "bad boy," in his meek, apologetic way and high pitched voice, when I find him being led home from some saloon by a couple of his children—who, poor little ones, have learned some of the bitterness this world can show.

There is, before attacks, a rise of blood pressure; possibly an attempt to wash out the faulty metabolism. The patient experiences a choking up of ideas and a false sense of increased power. He is hypertonic and hyperæsthetic. Peculiar emotional values become established, so that what is extraneous and superficial excites when no deeper feelings are aroused. In this state such patients could do murder for a drink—but would not tear or soil some valued paper or book; they cannot bear to hear a discord, perhaps, or see a false color harmony. The "will to be" is exalted and powerful, the patient believes. He can do some great work. He can resist temptation. Then comes the fear of failure. He braves it off. In desperation he attacks some work to do which is beyond him. His strength is spent. Then "just one drink, to rest me; that is all."

With the narcotic comes a heavenly sense of repose; now he will be all right and take no more. But the effect passes. He must go on. For a while relief is strong, then comes nervous reaction. Let the world die, but he must go on, on. There comes no stage of complete narcosis.

He lives in a state of peculiar quiescence, and belief of action that never occurs. He plans and proposes, but accomplishes nothing. The circuit of certain ideas is clear, but execution is wanting. He comes to a sense of double personality. He pities himself. He watches himself do those things he never thought to dare do. He gambles and frequents low dens. He is at variance with all he formerly held high and honorable; but not that he is changed.

I believe at the root of the man all this evil nature lay, and under the disorganizing stimulus the cloak is thrown away to reveal actuality.

Then, as the storm increases, if life is to continue, the force spends itself sweeping clear all the unholy accumulation. His desire vanishes in a moment, and disgust seizes him. It is not exactly repentance, for he can scarcely figure to himself his diseased condition in the calm of the clearing, although he recognizes certain of the evil effects.

A well dined person can scarcely picture to himself a state of extreme hunger—the dipsomaniac, once through a paroxysm, cannot imagine the state or causes of his failure.

"That is for the last time!" He will never again do what he regrets so bitterly—but the next year, the next month, may see him just the same or worse.

In the foregoing case is seen a man of neurasthenic type and of weak initiative with a highly strung, sensitive temperament, even of a poetic rather than practical turn of mind. His disgraceful condition and broken spirit establish in him an apologetic and miserable attitude. Let us turn to

CASE II.—Mr. J. T., aged 42 years, born in Lan-

cashire, England, married, and with a large family. The wife is of a nervous enough temperament, showing the misery of the life of privation which she has been compelled to lead. One son is a confirmed cigarette fiend, and neglects his work (in which he is quite skillful) for the slightest excuse. Another son is neurasthenic and of irregular habits.

Mr. T. began to show his predisposition while yet in England where, as he tells me, his aunt used often to plead with him month after month. In spite of many earnest promises he would succumb again and again. He came to America, where he has lived chiefly through the exertions of his wife and with some help in recent years from his boys.

His house is the typical drunkard's house. Some objects of value and many bare spots. A little store that the wife tried to establish was broken up through the stealing of its furnishings on the part of the unhappy husband. He has been often in jail. But the wife says that she has given over having him arrested—"it does no good."

As soon as he is in restraint a few days he becomes a different man—polite, keen, respectable, and a good mechanic. Every one takes a liking to the man; he is released.

In a few days it is an uncertain question what he will be. He may work six months, he may, in an hour, forget his pledge and come home in a mad, vicious condition to harm the boys and wife whom he ordinarily loves and regards. A month ago after striking his wife to force her to give him money, he was arrested and took the pledge for a year—on the way home he drank so much that he dared not show himself.

Mr. T. is of a full, hearty appearance. No drinking spree tells on him if he can get the chance to sleep twenty-four hours. He is a genial companion, and when not in an attack makes friends everywhere. When narcotized he is quarrelsome and vindictive, showing a disposition to be offended and make minor points excessive issues.

His face brutalizes and his movements are heavy. Yet there is an undercurrent of nervousness as evidenced by rigid pulse and increased reflex activity. He will not give up to anything but hyoscine.

As the impulse to drink subsides he begs to be put to sleep. He thinks if he could only be put to sleep, he mastered that is, there would be some hope for him. The mind of the dipsomaniac sees clearly the need of personal control through others, yet he fights this off with a desperation in earlier stages of the attack. I do not know but that in some cases the attack is to be taken as an integral part of the life cycle, or may be made to become so. At any rate, it is a successful way of terminating life, or, of eliminating whatever malignant forces are at work for the time being.

In all cases of weakened initiative I find the cardiac muscle and the vasomotor system in general, at fault; treatment along this line combined with companionship and suggestion yields the best results.

Certain conclusions may be arrived at with the above and other cases in view:

1. A change of scene is necessary. The patient comes to associate certain changes of his physical and intellectual breakdown with his ordinary occupations. This vicious circle must be broken up by outside influences.

2. In most cases of nervous disease some changes in the state of nerve conductivity are appreciable. As a rule, hypertonic conditions precede attacks; these are to be taken as part of a neurasthenic process. Later on this feverish activity brings about exhaustion which is more or less a matter of systemic concern. In any event, the plus condition is factitious and not a positive gain.

In the cerebral organism undoubtedly certain psychic circuits become established—those of the moral and higher intellectual values. Alcohol and other narcotics tend to break down this evolution. On the other hand, it is conceivable that an inordinate associative power may create an overplus of such higher intellectual values. The continuity of protoplasmic organism makes for tissue; psychic continuity is thought. In certain morbid processes excessive and improper tissue organization occurs. In neurotic individuals, instead of a diminished psychic activity, we may notice an actual excess of ideation. This may be along lines of ordinary or extraordinary correlation.

3. But, while certain extremes of environment are prejudicial to tissue continuity, so certain adventitious elements or excessive psychic activity may not make for the clearest consciousness. It may be asserted safely that attention and apprehension are elements of the higher consciousness and are the result of more or less perfect balance and superior coordination of psychic circuits. In neurotic individuals—epileptics, neurasthenics, dipsomaniacs, and the alienated in general—we might expect to find pathological circuits established in the intellect whereby certain reflex currents may be set in action, appreciable to the self or reflective consciousness, but out of its ordinary control. Dreams and the subconscious mental activity may be borderland effects of a similar exhibition.

4. In looking about for the reasons of these changes we must lay hold of either vasomotor and vascular modifications or essential nervous pathological processes.

In protoplasm there are four facultative aspects, namely, contractility, irritability, nutrition, and reproduction. In all the higher organized tissues these four are fundamental. Essential changes must be due to modifications of these

factors. A great many causes, intrinsic and extrinsic, are to be looked for as modifying influences. The effect on the individual of the four fundamental protoplasmic faculties may be summed up throughout his tissues as (a) the initiative reflex, (b) the temperamental reflex, (c) the nutritive reflex, and (d) the sexual reflex, respectively. These work out their influences according to the special nature of the tissues involved. It may be just as well when we can extend our knowledge of the influence of nutritive and therapeutic values to include their effects on the primitive protoplasmic powers and the organic reflexes therefrom.

5. It is our duty, in the matter of dipsomaniacs, as well as of other borderland cases of alienation, to educate public sentiment and to secure for them adequate places of treatment and opportunities of protected environment. Seclusion in a lunatic asylum is not the thing. The dipsomaniac has to sustain enough loss of self respect without having that pressure added too. Cases of transient mental affection ought by no means be associated with chronic or disagreeable manifestations of intellectual or nervous disease. I believe that relapses in melancholic cases may justly be attributed to the regimen or associations with which they have been made to feel the disgrace of such sickness. A certain attitude toward mental cases is very keenly appreciated by them, even if they are "insane." I have been able to verify this in confidential experience.

The dipsomaniac may be, and usually is, of enough intelligence to feel his situation deeply, and I believe that the open disgrace of alcoholism, and his belief in the impossibility of taking it from the memory of others, let alone himself, increases the chance of recidivism.

6. In treatment nothing equals the expulsive power of a new affection. Find the patient something safe, honorable, and interesting to do—something that is suitable for a patient of intelligence, but of neurasthenic trend.

THE MANAGEMENT OF PNEUMONIA IN INFANTS AND CHILDREN.*

By CHARLES GILMORE KERLEY, M. D.,

NEW YORK.

The child in health conforms within fairly definite lines to fixed habits of life. He is fed at certain intervals on food suitable for his age and physical condition. He is clad in seasonable clothing; baths, airing, a time for play and a time for rest comprise a general outline of his daily life. For every child there is a daily routine of living, depending, in its completeness, on the social position and intelligence of the parents, and on the physician's appreciation of the duty he owes to his charge.

Our first step in the treatment of an acute disease, such as pneumonia, in a baby is to change this régime of living as experience proves is required by the changed condition of the infant. Our first thought in the management of such a case is to establish a *sick room* régime. The surgeon, with much elaborateness, prepares his patient for the operation; and the postoperative management is characterized by the most careful detail. The physician may learn from the surgeon. In pneumonia we must prepare and place the patient in the best possible position to withstand the ordeal which we know must follow. In pneumonia we are dealing with an acute infectious disease which we cannot cure. Our efforts to relieve the patient must rest entirely in placing him so as to best resist, to wear out the infection and its effects upon the organism. Every child in health possesses a definite number of units of vitality, and these we must guard most jealously. Bearing in mind the thought of the preservation of the vital powers, I have found that one of the chief aids to this end is to keep the child comfortable. The infant which is made restless and irritable and sleepless by a hot room, overclothing, overattention, unsuitable feeding and unsuitable medication is greatly handicapped in the struggle for life.

My preparation or placing of an infant or young child ill with pneumonia is as follows:

The best available room in the dwelling is selected. If possible two rooms are used, one for the day and one for the night occupancy. The room should be kept at a moderate temperature—from 65° to 70° F.; it should be ventilated by a suitably protected window or windows. I have yet to experience any special benefit from the very low temperature. Reasonably warm air, at 65° F., can be just as fresh, just as pure as air at a temperature of 40° or 50° F.—in fact, it is my observation that I succeed best with sick infants when I avoid extreme measures. It is directed that the patient

* Read, by invitation, before the Harlem Medical Society.

shall be kept in bed the greater part of the time, and with but one attendant at a time in the room. Two women in a room invariably talk most of the time, and disturb the patient. It is also directed that the bed clothing and the clothing worn by the child be of the same weight and character of goods that he has been accustomed to in health. Oiled silk or cotton jackets are no longer used. One cleansing sponge bath is given daily. It is ordered that the food strength be reduced for the reason that the digestive capacity of a sick baby is always considerably diminished. One of the most frequent and dangerous complications of pneumonia in a young child is intestinal infection. The resulting toxæmia gives the child so much the more to bear, and the tympanites often seriously interferes with respiration. Children of the "run about" age, two to four years old, are allowed 50 per cent. milk (one half milk and one half water), broths, gruels, zwieback, toast, orange juice, prune juice, and thin stewed apple. Four feedings are given in the twenty-four hours, at four hour intervals. In the bottle fed it is my experience that the digestive capacity for milk is reduced at least one half. For the first few days of the illness the milk is reduced 50 to 75 per cent. by the addition of boiled water or thin gruels. It is desirable to feed the child to his full digestive capacity; well digested stools and the absence of tympanites must be our indications for increasing the food strength. For the breast fed the milk strength is reduced by giving a cereal water or a low percentage milk sugar water, one to three ounces, by spoon or bottle, before the nursing. There must be at least one bowel evacuation in the twenty-four hours; the urine is examined every third day.

Concerning the active treatment of pneumonia, I have no specific to offer, no special line of medication. The temperature of the patient should be taken by rectum every three or four hours. The indication for interference in the event of high temperature is not the degree registered by the thermometer, but the effect of the temperature on the patient. A temperature of 105° F. requires no interference if the child is quiet, with a regular, even pulse, and with the respirations under 50. A temperature of 103° F. with a restless, tossing child, with rapid respiration—50 or more, and a rapid pulse of from 150 to 180, may necessitate interference. Time and again the heart beats have been reduced 20 to 40 a minute, and the respirations 10 to 20 a minute by a properly applied pack—a means which I have found to be a most useful antipyretic measure. Now, mind you, I do not say a *cold* pack, or even a *cool* pack; but simply a *pack*. The pack is prepared as follows:

Over a rubber sheet is placed a pad or a thick

flannel blanket; on this the child rests. He is stripped, and the trunk is wrapped in a thick bath towel which has been moistened with water at 90° F. The legs and arms remain free, the patient is covered with suitable blankets. The result of this procedure is almost always gratifying—it produces no fright, no shock. The temperature is taken in half an hour. If no reduction has taken place the towel is moistened, without removing the child, with water from 5° to 10° cooler—with no other disturbance, or manipulation, then turning him first on one side and then on the other. The temperature of the pack may be in this way gradually reduced as indicated by taking the temperature every half hour. An intelligent nurse or mother will soon learn the degree of cold required to produce the desired result. In the majority of cases the fever will be reduced and the patient greatly benefited with the water at a temperature of not less than 80° F.; it is unusual that a degree of cold lower than 70° F. will be necessary. If the patient's temperature is reduced to 101° the pack is removed, and reapplied when the conditions require it. I have used this method in a great many cases and have yet to see it do anything but good. It adds greatly to the child's comfort—he sleeps better, the heart's action becomes stronger, the respirations diminish, and thus we preserve the vital forces. Cool spongings are sometimes useful; they require manipulation, however, and are apt to disturb the patient; they are ineffective if there is a high range of temperature. Cold enemata have not been of use in my hands.

If by the use of the pack I can reduce the heart beats 20 or 30 a minute I know that I am doing the patient a great service. In the management of pneumonia in infants the heart must be kept under close observation; in this connection drugs are invaluable. In giving drugs to pneumonia patients, however, it is to be remembered that the stomach, the receptacle into which the drug enters, is a most important organ; and drugs having a tendency to interfere with the digestion of food and derange the stomach are to be avoided. For this reason I rarely give digitalis or the ammonium salts, and never give the heavy, so called expectorant syrups. Strychnine and strophanthus as cardiac stimulants have answered my purpose well. From the standpoint of the stomach, and because of their effectiveness as heart stimulants, they have proved more useful than any other form of stimulant medication. As has been mentioned, we are not required to interfere with the temperature simply because the child has pneumonia. In like manner heart stimulants should not be brought into use merely because the child has pneumonia; to do so is a very common error.

The indication for heart stimulation is heart weakness. For the rapid, high tension pulse strophanthus is employed. For the irregular, soft, oft times intermittent pulse, with weakened first heart sound, strychnine is the remedy. It is usually given in too small doses. To be of any great service in extreme cases it must be given to the point of producing slight physiological effects. In alcohol we have a most valuable heart stimulant which is usually abused. It should never be given early in the disease except in the few cases that are grave from the outset. The continued administration of alcohol for several days in any form to babies is very sure to diminish both the desire for food and the digestive capacity. Furthermore, it is a cardiac stimulant which can invariably be relied upon to serve us for a short time. I like to hold it in reserve, to be used in time of great stress; so that when other means of stimulation fail, in the delayed crisis in the lobar type, for example, when there is intense prostration of all the vital forces, then alcohol may be used, and used in large amount, with signally beneficial results. In many severe cases strychnine and strophanthus are best given hypodermically. During the periods of great prostration the powers of absorption of the stomach are oftentimes nil. Nitroglycerin may be combined with any of the above stimulants when there are cyanosis and a tendency to cold extremities. The value of oxygen from the tank has to my mind been exaggerated. If more attention were given to allowing the oxygen to enter by the windows there would be much less occasion for the manufactured product. Given intermittently, as it often is, one minute, or two minutes, or five minutes, every half hour, it is of no service whatever. It is used with the best results when a constant, slow stream is allowed to play near the baby's face.

In many very severe cases proper feeding by the usual means is impossible. In such instances completely peptonized milk and other forms of nutrition and stimulation are given by gavage, using the ordinary stomach washing tube. Nutrient thus given is not repeated oftener than once in six hours. Useful often also, and frequently used, is the colon flushing with the normal salt solution. In a child taking but little fluid it is surprising to observe how much normal salt solution at a temperature of 100° to 105° F. will be drunk by the thirsty colon. I have repeatedly noted that the pulse and respiration improved and the stupor lessened as a result of colon flushings; this is to be explained probably, in that we increase the volume of the circulating medium, and thus lessen its toxicity upon the nerve centres. Completely peptonized skimmed milk and other nutrient substances are sometimes added to the salt solution. The nutrient

enemata or plain salt solution should be landed high in the colon by the means of a small rectal tube. The patient should rest on its right side, with the buttocks elevated while receiving the flushing, and remain in this position for a half hour thereafter. The fluid will be best retained if given warm; from 105° to 110° F.

Up to this time practically no reference has been made, no distinction, as to whether bronchopneumonia or lobar pneumonia was under consideration, for the reason that, concerning the management, thus far it is practically the same for the two common types, lobar and bronchopneumonia. In lobar pneumonia we have a self limited disease. We prepare the way and place the patient in the best position to resist, to take care of the infection. We endeavor to preserve his vital powers; and Nature, if she is kind, brings about a favorable termination. In bronchopneumonia we must perform all of these offices and more. Bronchopneumonia in babies does not possess the characteristic of self limitation. In this type in babies there are measures which directly assist in controlling the progress of the disease. Remedial measures which are of value in bronchopneumonia are steam inhalations, counterirritation, and to a lesser degree expectorants. For the usual case with teasing cough, rapid respiration, obstruction of the bronchi, and bronchial spasm I know of no more satisfactory means of relief than creosote steam inhalations. In using the steam inhalations the patient is placed in his crib, which is covered and draped with sheets so as to make a fairly tight, enclosed space. The apparatus necessary is an ordinary croup kettle. Ten drops of creosote are added to one quart of water and placed in the kettle. The nozzle of the kettle is introduced between the sheets at a safe distance from the child's face and hands, the steaming being carried on for thirty minutes every one, two, or three hours, depending upon the severity of the case and the relief afforded. The sheet should be parted slightly every ten minutes, so as to allow a renewal of the air. The inhalations are to be given both when the child is asleep and awake. As the patient improves the inhalations may be given at less frequent intervals than were found necessary at first.

The application of counterirritants to the skin over the thorax is a means of much service in cases in which there is evidence of much bronchial congestion and bronchial spasm; which covers most cases in the very young. In order that counterirritation may be of use a decidedly red blush must be produced on the skin. The old fashioned, home made, mustard plaster answers best as a counterirritant in my hands. Written directions are given as to its preparation and application. The thorax

is wrapped in it; and the application is repeated every six hours, usually for the first forty-eight hours. After this time it is used less frequently, or discontinued. With the combined use of steam inhalation and counterirritation I have in hundreds of cases given the child signal relief in relieving the dyspnoea, in relieving cough, in diminishing the bronchial spasm, and in lessening the rapidity of the respirations.

The use of the so called expectorant drugs in bronchopneumonia in infants is exceedingly limited; and a great deal of harm is often done to young children by the thoughtless use of drugs. Oftentimes, I fear, in our endeavors to assist the patient we harm him. In pneumonia in an infant we treat a disease in which the resisting powers count for everything. In young children the digestive function is very easily put out of order even in health. In illness, with fever and the nervous exhaustion attendant upon the illness, the stomach is easily disturbed; the child is not properly nourished, and the ability to resist the disease is lessened. Expectorant drugs, which may be of service if there is much bronchial catarrh, should be given with great care, and when used should be prescribed in tablet or powder form. The practice of using heavy syrups of wild cherry, tolu, and the like, with considerable doses of the ammonium salts, only adds to the burden of the patient. For a child one year of age, with the above condition, I occasionally give $\frac{1}{100}$ grain of tartar emetic and $\frac{1}{40}$ grain of ipecac after the feeding. In case the cough is very severe and teasing, and not relieved by the steam inhalations, a small quantity, $\frac{1}{4}$ to $\frac{1}{2}$ grain, of Dover's powder may be added to each dose.

Conclusion.—In the treatment of pneumonia in the young, the degree of our success is measured in large part by our ability to adapt the child to the unusual conditions caused by the presence of the disease.

A Floating Sanitarium.—The steamship *Fuerst Bismarck*, launched on March 22nd at Glasgow, has the distinction of being the first ocean liner designed especially as a floating sanitarium. She is a twin screw of 8,600 tons and is built for the Hamburg-American line. She will start on her first cruise on July 6th, covering 3,773 miles, stopping for a time at Guernsey, Bantry Bay, Stornoway, Leith, the Shetlands, Trondhjem, and Bergen. Dr. Schweninger, who was physician to Prince Bismarck, will personally supervise the cruises. He will be assisted by a corps of physicians, who will care for the health seekers free of charge. The cruises will be chiefly for convalescents and those in need of rest and recreation. The ship will have a gymnasium, electric baths, massage rooms, and all other equipments of a stationary sanitarium.

THE INFLUENCE OF INFECTED MILK IN THE DIET OF THE SICK—PARTICULARLY IN ACUTE INFECTIOUS DISEASES. WITH A REPORT OF A SERIES OF CASES OF MILK INFECTIONS IN TYPHOID FEVER PATIENTS.

By DAVID L. EDSALL, M. D.,

PHILADELPHIA.

(Concluded from page 582.)

The next most important possibility in controlling this danger is to have at least all milk used in the diet of the sick Pasteurized at the dairies where it is produced, or directly after its reception at the hospitals or homes in which it is to be used. This measure would in large degree obviate the evil effects of that portion of the milk which is bad, but there are a number of objections to Pasteurization. The first of these is somewhat theoretical, but is, I believe, based upon right reason; and also upon experimental observations, to some of which I have referred elsewhere. This objection is that milk is served raw by nature, and that in normal circumstances it is taken raw. It is known that heating milk causes many changes in it; and it is at least possible, I think, indeed, probable, that heating it even moderately may unfavorably alter its nutritive quality as well as its digestibility. I have seen scurvy develop in an infant soon after Pasteurization of its milk had been ordered, the milk having previously been unheated. I do not know that Pasteurizing the milk produced the scurvy, but I am quite willing to consider such a possibility, although the Pasteurizing was properly done by an intelligent mother. Similar observations, although uncommon when the milk is not heated to a high temperature, have been made by others. This objection applies chiefly to these cases in which milk must be used for a long time, but if it is a real objection it is also applicable to other cases and to adults as well as to infants and young children.

A second and more practical objection to Pasteurization is that many patients dislike or soon grow to dislike milk that shows by its taste that it has been heated. It is true that milk may be rendered harmless, or nearly so, from the standpoint of infection, by being subjected to a temperature lower than that necessary to alter its taste; but in carrying this out one goes very near the danger line, and it can be done safely only by an intelligent and conscientious person or with the aid of special apparatus.

Another objection is that Pasteurization is al-

ways bothersome, and it is difficult to get persons to carry it out carefully. Still another is that in any circumstances it needs care as to cleanliness, temperature, etc.; and, unless this care is devoted to it, Pasteurization may make a good milk bad, and may even make a bad milk worse.

A final and very important point, perhaps the most important of all, is that while Pasteurization protects against infection, it does not destroy the poisonous products of bacteria that may develop before the Pasteurizing is carried out; and these toxic substances may produce more or less grave symptoms. In this connection, it is of much interest to note that while, as I have stated, persistent diarrhoea and other severe abdominal symptoms almost entirely disappeared from my wards after Pasteurizing had been instituted, I have the records of ten cases during this period in which transitory, but sharp attacks of diarrhoea, lasting from a few hours to a day, developed in patients who both before and afterward had moderate constipation and who received Pasteurized milk. No other cause for this having been evident, it seems to me highly probable that it was the result either of poor Pasteurizing on these days, or of the presence of toxic bacterial products. The Pasteurizing had, I think, been satisfactory, and I believe that the other explanation is the correct one.

In the present state of the general milk supply, Pasteurizing is the best way out of the difficulty in case a thoroughly reliable milk cannot be secured, but the objections to Pasteurization that I have mentioned are real and important. It is almost unnecessary to say that the most certain way to protect patients is to see that, as far as possible, they receive milk that is produced, transported, and delivered under hygienic conditions. It is worth while to make this rather hackneyed statement only because it is even yet so little the general custom to appreciate this point and to insist upon it firmly. When dealing with young children, it is now considered the essence of carelessness to neglect it; with adults, on the contrary, both physicians and surgeons frequently still consider that the source of the milk is purely a domestic problem.

When one is treating the poor outside hospitals, circumstances justify this action or lack of action to a certain extent; for it is difficult for the poor to secure good milk, and almost equally difficult for them to keep it properly. It is, however, often surprisingly easy to convince those who are not quite paupers of the necessity of securing good milk for special purposes and of keeping it iced, even at relatively great expense.

With private patients of the well-to-do classes, the problem is simple in some of our large cities; for the patient can, and, at the word of the physician, usually does, secure milk whose reliability is certified to by a representative body of physicians. In much the greater proportion of our cities and large towns, however, the public spirit of the profession has not yet provided the safeguard of certified milk; and the consumer can determine which milk is likely to be good and which bad, only in case he or his medical attendant has acquired special knowledge concerning individual local milk dealers. Were the satisfaction that comes from having at hand certified milk that can be relied upon once generally appreciated by medical men in large towns and cities, I think that the energy and effort necessary to bring such milk into the local markets would soon be forthcoming in many places. When one has come to the habit of using such milk, one shrinks from permitting the use of unknown milk with the same feeling that one would shrink from ordering that a clean wound be dressed with a poultice. If, however, such milks are not at hand, it is certainly part of the rational duty of the physician to take pains, as a few doctors now do, to acquaint himself with milk dealers that make an earnest and well directed effort to furnish clean and properly kept milk; and also to see to it, as far as possible, that such milks become known to their patients and are used by them, during sickness, at least.

This statement applies with equal force to physicians practising in the country. There is a traditional belief that country milk is essentially superior to city milk; but—a paradox produced by the circumstances of civilization—it is, as a matter of fact, easier in most large cities, if a little effort be used, to secure a reliable milk, free from infection, than it is in most country places. A large proportion of country practitioners will find it difficult to discover nearby a satisfactorily clean and well managed dairy.

In hospital work the conditions are easier in some respects than in private practice, and in others more difficult. They are easier because the whole group of patients in an institution is under entire control, and if proper action is taken, it insures good milk for all without attention to individual cases. The conditions are, on the other hand, more difficult because it is always somewhat more expensive to secure good milk and keep it in proper condition than it is to pay a low market price to the most convenient bidder and keep the milk in the least troublesome and least expensive way possible; and administrative

officers of institutions naturally hesitate to go to what, in bulk, seems a very large expense, unless they can be convinced that it is important.

That this conviction has not yet been by any means generally reached by managers of institutions is evident from the fact that two years ago the "Committee on Milk" of the Keystone Veterinary Medical Association in an investigation of the milk supplies of over a hundred institutions in Philadelphia found that but an insignificant fraction of these institutions had any real knowledge as to the character or source of the milk that they used, the others accepting blindly what was furnished them. Dr. Leonard Pearson has kindly given me the summary of the results of this investigation so far as they relate to fifty hospitals. The questions investigated were the number of patients; the number of children usually in the institution; the number of quarts of milk used daily; and, in regard to this milk, whether its source was actually known, or it was merely bought from a dealer without determining what farms it came from; whether the source was inspected and the conditions existing there determined; whether it was customary to subject the milk to any form of test or examination; and whether the dealer was required to conform to any specific conditions other than the rather simple conditions required by our local laws. The results were extremely important, but extremely shocking. Of the fifty hospitals, two owned their source of supply. One other hospital knew the source, had it inspected, had the milk regularly examined, and required certain specific conditions of the dealer who furnished the milk. Ten other hospitals knew the source of the milk. Thirty-seven out of fifty institutions actually knew nothing about the milk that they received, except the man who sold it to them, and forty-seven out of fifty did not know the condition of the farms where the milk was produced, nor did they know the condition of the milk when it was delivered or when used by the patients, and no special requirements were imposed upon the dealer delivering the milk. Expressed in another form, in fifty hospitals 5,607 sick persons were on the average being treated each day, and 4,331 of them got milk of entirely unknown character as to cleanliness and safety; of these persons, 2,032 were children, of whom 1,917 got milk of wholly uncertain quality. In these institutions 3,443 quarts of milk were, on an average, consumed daily, and of this amount 2,313 quarts were of a wholly undetermined degree of cleanliness or uncleanliness, and over 500 quarts more were of very doubtful quality. Some of the farms from

which the milk came were investigated by the committee, and in a number of instances it was found that the milk was produced in some of the dirtiest and most unhygienic dairies in the eastern part of Pennsylvania. In one instance I investigated the chemical condition of the milk supply of a hospital in which most of the inmates are children. The chemical conditions that I found together with the bacteriological conditions that Dr. Evans kindly found for me, made it appear extremely probable that the milk supplied this institution was merely a mixture made up by the dealer from his old cream and separated milk. The bacteriological conditions in this instance were wretched, there being regularly many millions of bacteria, while the chemical conditions were utterly abnormal, the chief peculiarity being extremely low proteid (about two per cent.), and extremely high fat (eight to ten per cent.); and yet the administrative officers of this institution held that the children were getting an excellent milk because they "knew that the dealer was an honest man."

This rather appalling state of affairs I frequently hear attributed to the narrowness or rigid conservatism of hospital administrators. It is rather due ordinarily to the inaction of the attending staffs of the hospitals. The facts that I have given suffice to show that in typhoid fever—and if in typhoid fever, in other diseases also—infected milk may greatly endanger the lives of those to whom it is given, and may actually take life without even producing any clearly recognized specific disease. I am convinced that most hospital managers will appreciate this point if it is urged upon them with faith and energy by those whom they properly consider responsible for the welfare of the patients. Managers of hospitals have with great reasonableness told me in connection with this matter that they cannot be uniformly prepared to act on technical matters unless the necessity for action and the proper course to be pursued have been indicated to them. Together with most others of the educated lay public, they have been thoroughly convinced of the necessity of expensive measures to prevent surgical sepsis and of the dangers of narrow economy in such matters; and it requires only earnestness and determination to make it clear to any intelligent person that wound infection and gastrointestinal infection are not essentially different in their nature or results and may be of equal importance. Since the above mentioned investigation by the committee of veterinarians, the Hospital Association of Philadelphia, an organization composed of the chief administrative officers of

many of the hospitals of the city; has, largely as a result of the cheerful labor of Dr. Lawrence Flick, interested itself in securing improvement in the milk supply of the hospitals. It is in large part due to this action following upon the investigation by the veterinarians that some of the individual institutions that did not previously do so, now exercise chemical and bacteriological control of the quality of the milk instead of accepting it on faith. They also in some instances demand and determine that the dairies from which their milk comes shall be conducted with proper cleanliness and care, and that the milk shall be delivered immediately under good conditions as to temperature and cleanliness. Far more than this is necessary before the conditions in most of the hospitals can be considered to be anywhere near satisfactory, but the evil has at least been demonstrated and it is now readily possible to take effectual action if those in control desire to accept the opportunity.

At the Episcopal Hospital energetic action preceded any general movement. Previous to the observation of the conditions that I have described, the milk was merely obtained from a dealer supposed to be entirely reliable. It was not subjected to frequent bacteriological or chemical examinations, but it was not thought to have caused any trouble up to the period that I have mentioned. At this time the observations made by Dr. Miller and myself were brought to the attention of the managers, who immediately interested themselves in the matter; and we now have a supply from an approved source, the milk being produced and handled under satisfactory conditions as to general cleanliness and care of the utensils and of the cattle, and kept properly cooled. It is not allowed to stand indefinitely on the station platform upon its arrival in the city, but is immediately delivered at the hospital. When it arrives there it is at once placed in a central distributing station, where it is kept at a temperature running almost always from 43° to 45° F., and never going above 48° F., the temperature of the milk upon its arrival having always been previously taken and recorded. A graduate nurse is in charge of the central station, and is responsible for it in all ways; for its cleanliness, the temperature of the milk, the distribution of the milk to the wards, the care of the vessels, etc. When the milk is received in each ward, it is put into special vessels which are tightly closed. In each ward one nurse is responsible for keeping the milk properly cooled and clean. Bacteriological and chemical tests are frequently made, and their results recorded. The chemical tests have

always been entirely satisfactory, while the bacteriological have been most excellent. For months past the milk has been delivered at a temperature that was almost regularly below 50° F., in a few rare instances going as high as 52°; and since the regulations in regard to the temperature at delivery have been carefully complied with the bacterial counts have been very low, almost always, indeed, within the requirements of the New York certified milk.

This milk costs a cent a quart more than that previously in use. When one realizes what an enormous amount of milk is used in a large hospital, one cannot overlook the fact that an advance of more than twenty per cent. in the price is a considerable item in the yearly expense account. One can hardly doubt the advisability of undertaking such an expense, however, when one considers that in a hospital, milk is the chief food article; that it, especially, is the main food of the patients that are seriously ill; and that it is, at the same time, much more likely to be contaminated with pathogenic organisms and to become a flourishing bacterial culture than is any other food as foods are generally handled. When the last mentioned facts are looked at fairly, there can, of course, be no question that good milk should be secured, if any is to be had, even if this necessitates retrenchment in other directions. The price that I have mentioned shows, however, that good milk can be obtained at a relatively small advance upon the price of uncertain or bad milk if some trouble is taken, in the first place, to determine that the dairy and the methods in use there as well as the subsequent handling of the milk are satisfactory, and if these points, as well as the chemical and, particularly, the bacteriological condition of the milk are kept under supervision, in order to determine that the dealer is carrying out his contract with honesty and intelligent care.

I have insisted upon the importance of hospital action in this matter because the public is accustomed to look to hospitals to lead in hygienic advances and the hospitals cannot afford to shirk their duty.

The road to a general sanitary milk supply does "lead up hill all the way," and the way is a very long one, but many of the rough places would be smoothed away at once, if the administrative officers and the attending staffs of a large proportion of hospitals took definite and determined action. The courage that this would lend to the general cause; the immediate warning that it would give to all sensible milk dealers that they must look to their methods with care, or soon be

left in the rear; and the ultimate benefit to sanitation; all these would be of an extent and importance that cannot be over valued.

Together with the hospitals, physicians, and veterinarians in country regions have a most valuable opportunity to act as leaders in this cause. A good deal of the evil that now exists is due to the ignorance of most farmers as to the fact that there are evils and as to the methods by which conditions may be improved without great expense. Doctors of medicine and of veterinary medicine who practise in the country could, by quiet suggestion, do much to increase the knowledge of the producers concerning these points.

I have made no special reference to the literature concerning the epidemics of disease that have resulted from milk infection, or to that discussing the differences between sanitary and insanitary milk and the practical methods of producing the former. References to the most accessible and valuable articles on these questions may readily be found in Freeman's tables;¹ in the recent excellent collection of literature by Plaut,² as well as in articles in the same publication by Glage, Sieveking, Rosatzin, and others; and in the extremely striking monograph by Kober.³ The latter contains, besides Dr. Kober's important article, a valuable description, by Mr. R. A. Pearson, of the essentials in the production of good milk.

Tuberculosis in Boston.—At a meeting of the Brookline, Mass., Medical Society last month, Dr. Edward O. Otis said there were more than three thousand persons in Boston suffering from pronounced tuberculosis in its various stages. The deaths from the disease in 1903 numbered 1,227, and in 1904, 11½ per cent. of all the deaths in Boston were caused by tuberculosis. Most of the hospitals closed their doors to the sufferers from this disease, and consequently provision for the care and treatment of consumptives was totally inadequate, notwithstanding that special provision was made for them by the pauper and penal institutions of the city and that a few patients were received in the private hospitals.

A Denial by Dr. Councilman.—Dr. William T. Councilman, of the Harvard Medical School, it is stated, has said that there is no truth in the report from Baltimore that he had been chosen to succeed Dr. William Osler at Johns Hopkins University. He said that Dr. William Welsh, of Johns Hopkins, called on him recently, but nothing was said with regard to Dr. Councilman going to Baltimore. In any event, said Dr. Councilman, he could not be chosen as Dr. Osler's successor, as he is a specialist in a different field.

SOME CLINICAL DEDUCTIONS FROM THE PERFORMANCE OF NINETY ALEXANDER OPERATIONS WITH ABBÉ'S MODIFICATION.

By H. B. EPSTEIN, M. D.,

NEWARK, N. J.

In the months of November and December, 1890, the writer was called to attend two women in labor; the first, Mrs. S. W., had a ventrofixation performed when single. The second, Mrs. L. E., had the same operation performed after the birth of her fourth child. Both of these cases were attended with severe post partum hæmorrhage which in each case required the almost continuous attendance for twelve hours of a physician and nurse until the uterus was thoroughly contracted. In both cases there were extensive adhesions which interfered with the uterine contractions.

About that time Duhrsen, Mackenrodt, and other surgeons who had performed some 2,500 ventrofixations, commenced to report complications and fatalities resulting from this operation, with the result of abandoning that procedure for vesicouterine fixation and the Alexander operation.

On October 14, 1896, Abbé read his paper before the New York Surgical Society, recommending his technics in preference to the original one of Mr. Alexander, of Liverpool, England, and the writer especially desires to call attention to the Abbé technics which has given such satisfaction in this series of ninety cases.

Let us now consider the various phases of retroversion and prolapse of the uterus.

First, we have descent and backward displacements in the nulliparous female, uncomplicated, unless by an endometritis; then those in the multipara; this condition associated with cervical ectropion and erosions; cystocele, rectocele, hæmorrhoids, and occasionally incarcerations of the fundus in the hollow of the sacrum.

It is in this group of cases that we have the particular indications for the above named operation after the plastic work has been performed.

On the other hand, we have retrodisplacement or prolapse of the uterus, attended with the formation of adhesions, diseases of the ovaries, Fallopian tubes, the vermiform appendix; the large subinvolved uterus following sepsis, chronic metritis, and tumors which contraindicate its performance.

Of the series of ninety cases the writer has delivered eighteen women without a relapse in any case. In seventy-six cases he has had the oppor-

³ U. S. Senate Document No. 441, Milk in Its Relation to Public Health.

tunity of seeing his patients for other illnesses or they have reported for examinations and in no case has relapse occurred.

In forty-two cases the operation was performed for simple retroversion; curettage was supplemented for the attendant endometritis.

In twenty cases retroversions were accompanied by prolapse, in which, in addition to curettage, anterior and posterior colporrhaphy was added; in eight cases excision of hæmorrhoids was performed and four divulsions for fissure in ano were done.

In the last eight years other modifications have been suggested: those of Dudley, Montgomery, Baldy, Guillian, and others. In these operations the whole ligament is either folded, tucked, or drawn through other tissues in the most complicated manner and all have been declared faulty, owing to the fact that the ligaments have weakened and attenuated through prolonged overstretching; again, they deal with the whole ligament, whereas the uterine end for obvious reasons is the only portion which should be made to hold up the uterus.

Many of these modifications necessitate the performance of laparotomy, whereas the Abbé modification is an operation attended by no risk, is not followed by peritoneal adhesions or hernia, and may be called a minor operation. One must of course be prepared to meet surprises in this as in all other surgical proceedings. For instance, in the thirty-fourth case, while isolating the right ligament, we encountered considerable hæmorrhagic ooze from the inguinal canal. The source of the bleeding was traced to a varicose condition of the veins anastomosing with the pampiniform plexus, but by stripping back the funicular process the injured vein could be, and was, ligated. During these manipulations, a very small subserous fibroid was located on the lateral side of the uterine fundus, so the funicular process of the peritonæum was incised and the fibroid evulsed by means of a small forceps. Rarely a varicose condition of the pampiniform plexus exists, and may be met with by this means, and this case shows that one is not necessarily obliged to do a laparotomy in the classical way, every time a complication is encountered.

In four cases considerable annoyance was caused by pain in the scars; two cases required the dissection of the genital branch of the genitocrural nerve, owing to its inclusion in the cicatrix. The other two responded to mild galvanism.

The technics is essentially the same as Abbé's.

Preparing the patient with the same care as for cœliotomy, an incision is made starting at the pubic spine upward and obliquely outward one half inch, above and parallel with Poupart's ligament. The skin, fat, and superficial fascia are divided and each layer is separated on each side for one and one half inches; the aponeurosis of the external oblique muscle is incised. The external abdominal ring should now be located one half to three quarters of an inch above and outside of the pubic spine. This is the most important landmark. At this point a lump of fat presents. Now, by hooking a director underneath the aponeurosis the round ligament will be found. If any difficulty is experienced, the fingers in the wound plus the counter pressure over the site of the ligaments will present a cord-like feel, which is the ligament. The ligament should be lifted out of its bed in the inguinal canal and further identified by the funicular process of the peritonæum which invests it.

This process is stripped back as far as the internal inguinal ring. This being done, a piece of gauze is slipped underneath and the same procedure performed on the opposite side. The writer has often found a large, thick ligament on one side and a thin, thready one on the opposite side.

The ligaments now being isolated are now cut off at the distal end and the cornua of the uterus pulled up taut, then an interrupted suture is passed through the internal oblique, the ligament, and Poupart's. This ligature is drawn tight, while the ligament is being pulled upon.

A Cleveland ligature is made to pierce the internal oblique and passed below Poupart's ligament in the same manner as sutures are inserted in a herniotomy, with the exception that the round ligament is used as a continuous suture (see *Annals of Surgery*, Vol. XXIV, page 702). Thus the inguinal canal is closed, using the round ligament as a continuous suture. Each puncture through the internal oblique is fixed with a medium catgut suture. The aponeurosis and fascia are sewed separately with continuous fine catgut. The skin is sewed with silk worm gut.

There is hardly a condition from which women suffer which is so amenable to treatment as retrodisplacement and prolapse, and that with practically no danger. The writer therefore heartily endorses this method which has given such satisfaction, and he believes that after an impartial trial of the Abbé method, it would soon displace all the other methods.

CEREBROSPINAL MENINGITIS IN
CATTLE.By PAUL SHEKWANA,
IOWA CITY, IA.,

BACTERIOLOGIST OF THE IOWA STATE BOARD OF HEALTH.

The object of this article is to draw the attention of the medical profession as to the possible sources from which cerebrospinal meningitis may spread. Until very recently it was believed by all that this disease occurred only in man. Later, however, a few cases have been recorded by the Minnesota State Board of Health which show that it occurs in cattle also.

On February 20, 1905, Dr. H. E. Talbot, of Des Moines, submitted the brains of two cattle to be examined at the laboratory of the Iowa State Board of Health in Iowa City. This gentleman stated that a number of cattle had been dying in the neighborhood of Colfax of an epidemic of a perplexing disease, which he thought to be some form of meningitis. He wanted to know if it was infectious or contagious. Professor H. Albert, the director of the laboratory, and the writer inoculated a rabbit under the dura mater with 1 c.c. of an emulsion made from the two brains. The animal died after thirty-six hours, showing before death and at the post mortem examination all the signs and symptoms of cerebrospinal meningitis, retraction of the head, thrombosis of the blood vessels, softening of the brain, and exudate about the meninges, etc. The microscopical and cultural examinations also proved it to be the disease in question. The slide preparations from both the original brains and from the brain of the rabbit inoculated by us showed a great number of *diplococcus intracellularis meningitidis*, some within and some outside the cells.

From this case and those examined by the Minnesota Board of Health, it is evident that the disease is much more widely distributed than it was at first supposed to be. Therefore it becomes a subject of the greatest importance and interest to all medical men as well as to the public in general to know the sources from which the disease may spread and thus to guard against infection from it.

We know for certain that cerebrospinal meningitis is an infectious disease, occurring generally in epidemics in man; but now we have reasons to believe that it occurs in cattle as well. Whether man infects cattle, or cattle infect man, it cannot be definitely said, but certain it is that the disease attacks both animals. From this fact it can be reasonably inferred that one mammal infects the other and vice versa.

The question then arises: Is it not quite possible that cattle have been the source of infection in some of the epidemics occurring in man? In cerebrospinal meningitis there is usually a discharge from the nose, and this discharge contains *diplococcus intracellularis meningitidis*, and thus becomes the principal source of infection. On account of this great danger, care should therefore be taken by all those who come in contact with cattle suffering from the disease.

Cerebrospinal meningitis, then, must be considered to be a malady which not only affects man, but cattle as well. The disease probably affects other lower animals, too, though in regard to this point we have at present no definite knowledge.

Therapeutical Notes.

NOTES ON THE NEWER MATERIA MEDICA.

Adrenalin Gauze.—The remarkable capillary contracting action of adrenalin has been utilized by a firm of antiseptic dressing manufacturers in Chemnitz, who are introducing surgical bandages impregnated with the substance, the whole being sterilized.

Aganin is the name given by an apothecary in Krems, Germany, to a syrup of potassium sulphoguaicolate.

Aqua ρ is described as a distillation product of radium chloride solution.

Astmol (Dr. Elswirth's asthma compound) is now put up in the forms of fumigating powders and cigarettes.

Bismuth ρ is a radioactive bismuth subnitrate obtained by the action of radium bromide on the first-named salt.

Bromoil, in a dry powdered form, is made by emulsification (of bromine?) with condensed milk and drying in a current of air.

Calomelosalbe (Unguentum Heyden) is a soft ointment of a grayish color containing 30 per cent. of calomelol (colloidal calomel) and 2 per cent. of mercury. It is used in the treatment of syphilis.

Candol is the name given to a dried malt extract of high diastatic power.

Capsolin, which is recommended as a substitute for mustard papers, is said to consist of a mixture of oleoresin of camphor, the oils of turpentine, cajuput, croton, with an ointment base, made and marketed by Parke, Davis & Co., Detroit.

Capsules Dartois have the size of an ordinary pill and each capsule contains 0.05 gm. beechwood creosote and 0.2 gm. of cod liver oil.

Cardiolo is an alcoholic extract of squill, lobelia, strophanthus, and nux vomica, with guaia-col.

Cephalopin is an oily extract prepared from

fresh nerve substance. It is supposed to contain myelin, lecithin, and such other constituents of the nerve substance as are soluble in oil. It has been suggested for use as an antidote to strychnine, and is administered hypodermically in the treatment of neurasthenia, hysteria, neuralgia, etc.

Cetiacol (or **Palmiacol**) is the subject of a patent issued to L. H. Cress, of Fremont, O., in which it is described chemically as "cetyl guaiacyl." It is probably pyrocatechin-methyl-cetyl-ester. It is insoluble in water, but dissolves readily in alcohol, ether, and chloroform. It is credited with properties similar to those of guaiacol, and is recommended as a specific in tuberculosis.

Chinolio is the name applied to an oleaginous powder composed of 80 per cent. of quinine sulphate and 20 per cent. of a mass composed principally of olive oil. The powder is miscible with wine and syrup and is given in 0.3 gramme doses every three or four hours in grippe, myalgia, and feverish conditions.

Chloræthoform is a chloroform containing 0.25 per cent. of ethyl chloride, which has been recommended as a safer and more certain anæsthetic than the plain chloroform.

Cholelithmin is a weak alcoholic solution of the fresh bile of animals which have been fed with recent biliary secretion. It is stated to be practically a dilute alcoholic solution of salts of the bile acids and of albuminoids, and is recommended in the treatment of biliary colic.

Citon tablets, recommended as purgatives, are put up in two forms, white and brown, the white consisting of 0.1 gramme paraptalein (? phenolphthalein), 0.5 gramme sugar and 0.01 gramme menthol, and the brown, paraptalein (? phenolphthalein), 0.1 gramme; sugar, 0.5 gramme; vanillin, 0.002 gramme, and chocolate, 0.1 gramme.

Citronal pills contain in 100 0.5 gramme quinine hydrochloride, 10 grammes citric acid, 6 grammes extract frangula, and 4 grammes extract of whortleberry leaf. Recommended in gout, rheumatism, etc.

Citramine oxyphenylate is said to be a mixture of equal parts of hetralin (resorcin-hexamethylene-tetramine) and helmitol (anhydro-methylene-citric acid-hexamethylene-tetramine).

Codliver oil substitutes are made according to a patent taken out by K. F. Tollner, Bremen, Germany, by the following process: Certain kinds of marine algaecious plants—i. e., seaweeds and the like, such as *Laminaria digitata*, *Laminaria saccharina*, *Fucus serratus*, *Fucus vesiculosus*, which are rich in iodine, are dried, and, after cutting them into pieces, roasted. They are then finely pulverized and the powder immediately mixed with a suitable fatty oil or oils, preferably sesame oil, peanut oil, or their equivalents. After about a week, during which period the mixture is repeatedly shaken, the liquid parts of the mixture are separated from the solid by filtration or otherwise. The resulting oil is again filtered and is then ready for use. The proportions are one part by weight of algaecious plants to nine parts

by weight of oil. Where the structure of the plants is somewhat close it is of advantage to first mix the powder with alcohol—preferably equal in weight to the weight of said powder—and to add the oil after the expiration of some days. The alcohol may be removed from the oil afterward by slightly heating.

Colalin, which is described as the active principle of bile, is an amorphous white powder of intensely bitter taste. It is said to be insoluble in the acid contents of the stomach, but soluble in the alkaline contents of the upper intestines. It is recommended in the treatment of jaundice, gall stones, etc.

Convulsin consists of a specially prepared fluid extract of eucalyptus mixed with syrup of vanilla, which is recommended in the treatment of coughs and diseases of the respiratory tract.

Copper aseptol is another name for copper sulphocarbonate.

Corticin is announced as a new name for the caffeine-quinine compound known as basicin.

Cotargit is a double salt of cotarnine hydrochloride and ferric chloride which forms ruby red crystals having a melting point of 104° to 105° C. It possesses strong hæmostatic properties and is used to check hæmorrhage.

Creosotina represents a beechwood creosote that has been subjected to repeated purifying processes and combined with carbonic and benzoic acids. It has a pleasant aromatic odor and is easily borne by the stomach. It is said to possess all the antiseptic properties of creosote without its disadvantages.

Curaril is represented to be a stable, very active liquid preparation of curare which has been found efficacious in tetanus. It is a very powerful solution, and is administered hypodermically in doses of 2.4 c.c. If, after half an hour, no effect is obtained, the dose is repeated with an increase of 0.20 c.c. of the remedy (1 c.c. of which can kill 50 mice) every two or three hours until relief is obtained. It is marketed by the Dr. Heinrich Byk Chemical Works, Berlin. [It may be noted that doubt has been expressed regarding the real composition of this liquid, R. Boehm (*Therap. der Gegenwart*, November, 1904) describing it as a ½ per cent. solution of the weak calebassic acid.]

Curbitin chocolate, a new worm lozenge for children, consists of a mixture of powdered pumpkin seeds and chocolate.

Damholid is a preparation of hæmoglobin intended for the treatment of anæmia in cattle. It comes in three forms, from the laboratory of Felix Wecker, Jr., Rostock, Germany, viz.: Damholid liquid, containing 40 per cent. of pure hæmoglobin; Damholid I, a dark brown, granular, odorless powder, readily soluble in 8 parts of cold water; Damholid II, a fine, brownish red powder, equally as soluble in water as the preceding. The remedy is given in anæmia of steers in the following doses: Of the liquid, 26 Cc.; of Damholid I and II, 50 Cc. of a 20 to 25 per cent. solution.

NEW YORK MEDICAL JOURNAL

AND

PHILADELPHIA MEDICAL JOURNAL.

A Weekly Review of Medicine.

ESTABLISHED IN 1865.

Edited by

FRANK P. FOSTER, M. D.

Published by the

A. R. ELLIOTT PUBLISHING COMPANY.

Remittances should be made by New York Exchange or post office or express money order payable to the A. R. Elliott Publishing Co., or by registered mail, as the publishers are not responsible for money sent by unregistered mail.

Address all communications to

A. R. ELLIOTT PUBLISHING COMPANY,

66 West Broadway, New York.

Entered at the Post Office at New York and admitted for transportation through the mail as second class matter.

NEW YORK, SATURDAY, APRIL 1, 1905.

JOURNALISTIC HYSTERIA.

It is well known in the offices of medical journals that the business managers of the various publications are perpetually striving to get the better of each other. Their doings in this endeavor are frequently the subject of talk in the offices, but they are not dwelt upon to any noteworthy extent. We have always thought that it would answer no good purpose to refer to them in print, and our observation has been to the effect that our contemporaries were of the same opinion. But the *Journal of the American Medical Association* has broken away from this dignified position. In its issue for March 25th there is contained a vicious and scurrilous attack on the president of the company that owns and publishes this journal, Mr. A. R. Elliott, and incidentally on the journal itself and on its editor. The article is based on a letter sent by Mr. Elliott, as president of our publishing company, to certain manufacturing pharmacists, inviting them to give their views concerning the American Medical Association's recently promulgated rules for estimating the ethical status of proprietary medicinal preparations. The article published in the *Journal of the American Medical Association* is so undignified and so hysterical that we cannot account for its appearance except on the supposition that our Chicago contemporary felt itself to have been hard hit by Mr. Elliott's letter, and that, we think, will be the

interpretation put upon it by the great majority of readers. Not only has our contemporary's equanimity been ruffled, but it seems to have feared that its veracity might be called in question, for, instead of simply quoting the text of Mr. Elliott's letter, it gives up nearly an entire page of its valuable space to a full sized fac simile reproduction of the letter—a "yellow" procedure to which it would hardly have resorted save under the pressure of such fear. The excuse given for this reproduction is that the letter is "so unique."

The writer of the article assumes that in issuing the letter Mr. Elliott temporarily usurped the function of the editor of this journal, and that he is in the habit of doing so, for the writer goes on to say: "There was a time when the *New York Medical Journal* held a high position among medical journals of this country. It stood for the ideal in medicine and for the profession it represented. But that was when it was owned by the Appletons, when Dr. Frank P. Foster was editor in fact, and who, as such, would not have advocated in its editorial pages secrecy in medicine."

As regards the case in point, correspondence with manufacturers, either to ascertain their views or for any other purpose, we do not look upon as the editor's function; therefore, there would not have been in any event a usurpation of that function in the issue of the letter. As a matter of fact, however, the editor was consulted before the letter was sent out, and he entirely approved of it. The proposition to devote some space to manufacturers' expressions of opinion seemed to him unobjectionable, particularly in view of the fact that such space was not to be included in the reading pages of the journal, a fact that was to be clearly indicated. As regards the general implication that the editor of this journal is no longer the "editor in fact," we wish to say emphatically that he is absolutely untrammelled by the publishers. If during the time that this journal has been owned by the A. R. Elliott Publishing Company it had failed in any respect to live up to its former reputation as an exponent of the true interests of the medical profession, its failure would not have been due to any shortcomings on the part of the publishing company. But there has not been any such failure. On the contrary, it holds in the esteem of the profession a higher position than it ever held before. This we

are justified in saying on the strength of the frequency with which the leading physicians of the country, including many of the American Medical Association's foremost members, contribute to its columns, and on the strength of its greatly increased circulation, which, in spite of the *Journal of the American Medical Association's* innuendo, is larger than that of any other weekly American medical journal that has not its following largely ready made for it by membership in some organization. Moreover, our present publishers have so added to our resources as to enable us to increase the number of reading pages very decidedly.

The *Journal of the American Medical Association* sneers at the president of our publishing company because he is primarily an advertising agent, as if that fact disqualified him as a publisher, and again it descends to the "yellow" methods by giving a fac simile reproduction of one of his letter heads. We understand that Mr. Rockefeller is prominent in the affairs of the Standard Oil Company. Does anybody imagine that that fact taints the Rockefeller Institute for Medical Research? But we have said enough of the "nasty" article in our Chicago contemporary; it is merely an exhibition of journalistic hysteria.

QUACKS AND NEWSPAPERS IN CRIMINAL ALLIANCE.

Mr. Champe S. Andrews, the counsel of the Medical Society of the County of New York, delivered before that society a few weeks ago a very illuminating address entitled *A Century's Criminal Alliance between Quacks and Some Newspapers*. There can be little doubt that, as regards some of the newspapers, Mr. Andrews is quite justified in using the expression "criminal alliance," for he explains that they charge more than their ordinary rate for printing the advertisements of certain classes of quacks, which they would not be likely to do, we suppose, except with some notion of salving their own consciences by mulcting the quacks, whom they must know to be downright swindlers. Besides their own swindling, who can tell to what extent the quacks tempt their victims to acts of dishonesty committed for the sake of obtaining the money necessary to satisfy the quacks' rapacity?

The struggle against quackery is not very hopeful, and the fault does not lie with the county

society, in spite of the newspapers' insisting that it does, for the most dangerous of the quacks either are qualified practitioners, and consequently cannot be prosecuted for violating the medical practice law, or else deal with a class of victims who for very shame cannot be induced to appear in court against the swindlers. Newspaper advertising is the chief means by which the quack secures his victims, and something might be done, as Mr. Andrews tells us has been done in Michigan, by making certain forms of quack advertising a penal offense. We hope, therefore, that Mr. Andrews's address will meet with due consideration at the hands of our legislators.

WOMEN'S SUCCESS IN STATE EXAMINATIONS.

Widespread comment has recently been made in lay journals regarding the remarkable achievements of women in State examinations for the license to practise medicine. As a matter of fact, women do usually rank very high in such tests. From this isolated fact, however, we are not justified in attributing a superior intellectuality to the girl students. State license examinations are almost invariably of such a character as to call into play only the lowest of all the mental faculties—the memory. There is nothing in such an examination on any subject to prevent a bright boy of seventeen years or younger from making a brilliant showing when his knowledge of the subjects discussed might be based on mere book learning and be of no practical value whatever.

A retentive memory is often characteristic of people with very low powers of generalization. The distinguished Lord Macaulay is the only brilliantly clever man we can instantly recall as being noted for his marvellous memory. Porson, the Greek scholar, was noted for nothing else. The blindfolded chess players whose mnemonic feats seem so extraordinary are seldom persons of any intellectual force. On the other hand, we know many gifted men in various walks of life, whose judgment and mental precision are highly valued, who are obliged to note down the small essentials of their calling and to have such notes ready for immediate reference. We must not be considered as being so ungallant as to deny intellectual equality in women with men, but we must emphasize the fact that the possession of a retentive memory alone is not an argument in

their favor. The well known frequent failures of gold medallists in after life illustrates our point; as long as memory is the only factor in success, they shine. When, however, initiative, judgment, the power to deduce from accumulated experience, and the other faculties of a well balanced mind are drawn upon, they fall by the wayside, much to the wonder, generally, of their unobservant friends. Memory is a primitive quality and is best developed in primitive characters; with the invention of writing it began to decline, and it has been much crushed by the printing press. Much higher qualities are needed to win the battles of modern civilization.

PARÆSTHETIC MERALGIA.

The history of paræsthetic meralgia is most curious, because it shows, in spite of the extraordinary activity of neurologists, that it is still possible to discover a new disease, and what is still more singular is the fact that this recently described affection had never been brought to light until the nearly simultaneous writings of Roth and Bernhardt, in 1895. Since this time a number of cases have been recorded, so that it would appear that the disease is by no means uncommon. When paræsthetic meralgia occurs in its typical form the patient is aware of an abnormal sensation at the antero-external aspect of the thigh, and this is present whether the subject is standing, walking, or in repose. Under certain influences this sensation may be transformed into pain, occurring in paroxysms and more or less intense.

The characters of the paræsthesia vary. In some cases there is a malaise which is difficult to describe, while other patients feel a deep twitching which they liken to muscular retraction. Still others have the sensation of dead skin, a piece of wood, or a paste-board cast laid in the integuments of the thigh. Frequently there is a constant numbness present, accompanied or not by prickling or stinging sensations. The paroxysms of pain become grafted upon the common ground, which is the paræsthesia. The action of a particular causative factor is necessary for the production of pain, and this cause, which intervenes in keeping up and especially in producing the recurrence of the paroxysms, may in itself prolong the affection. The exciting causes of the attacks are slow or rapid, long continued walking, standing

for some time, or going up stairs. Slight or strong pressure on the thigh produces the paroxysms, and in some cases even the friction produced by a bunch of keys in the trousers pocket or by the bed-clothes may be enough.

The paroxysm may consist of a mere exaggeration of the paræsthesia or there may be subjective symptoms added to it, but more frequently pain appears, which is compared to a sensation of burning, the intensity of which may be so great as to cause the patient to cry out or to limp. The seat of these painful phenomena corresponds to the area of paræsthesia. The subject is frequently obliged to stop in his walk and to sit down when he is standing and rest the limb for a little time in order to quiet the intense pain. The attack may sometimes be stopped by lying down, but, on the other hand, it may persist during repose. The dorsal decubitus has been known to cause the pain to come on, especially if the thigh is extended, but this may occur in the erect position. On the contrary, rapid flexion of the thigh may put an end to the pain, as well as to that produced by walking, in some instances. In one case reported by Sabrazès and Cabannes the patient inclined his body forward and flexed the leg on the thigh to relieve himself of the paroxysm, and they make the remark that a medium amount of flexion, combined with outward rotation, was the easiest position for the patient to assume. Exceptionally the paroxysms are wanting, and in these cases a more or less acute paræsthesia may alone exist or be accompanied by objective disturbances of the sensibility. Very rare are those instances in which paræsthesia is absent with only objective disturbances present.

In all reported cases paræsthetic meralgia has been seated in the anteroexternal aspect of the thigh; in thirty-eight it was on the left side and on the right in thirty-seven. The disease began in both thighs in nine cases and became bilateral secondarily in eight others, under which circumstances the paræsthesia predominated, both in intensity, and in extent, in the thigh first involved. In twelve reported cases the side involved is not mentioned. Hypothermia of the involved area has been noted twice, the first time in 1898, by Joncheray, but without any thermometric record, while the second instance was observed by Sabrazès and Cabannes, who found a difference of about 5° F. in favor of

the healthy thigh. The area of paræsthesia extends from the anterior superior iliac spine or the great trochanter to the external condyle of the femur. Anteriorly it is limited by the middle line of the thigh, and posteriorly by the sciatic nerve.

The abnormal sensations become more marked as the centre of the area is approached, and are greatly attenuated at its borders. There are exceptions to this rule, and cases are on record in which the paræsthesia was quite as intense at the borders as in the centre of the area. In others it was the lower and median portion of the thigh where it was most marked. The paræsthetic area is not always so large as has been described, and one may meet with cases in which circumscribed zones are found, but these will be invariably within the area already referred to. These small zones are isolated from each other and their borders are irregular. They were found in five cases at the upper part of the thigh, at the middle in three, and seven times at the lower part. In contour they are round or oval, and vary in size from that of the palm of the hand to that of a silver dollar. When two plaques are present, one is usually larger than the other.

In exploring the region to ascertain the objective disturbances, it will be noted that they exactly occupy the same area as the paræsthesia, but in one case points of analgesia were found scattered here and there. Partial hypæsthesia was present in fifty cases, while in twenty-seven others it was evident to the touch or on pricking. In nineteen instances tactile hypæsthesia and hypalgesia were equal. In five cases a tardy perception of contact or pricking was found. Tactile hyperæsthesia is mentioned in eleven cases, and in five digital pressure on the centre of the paræsthetic area produced a paroxysm of pain. Friction of the skin or picking it up caused an intense burning sensation in thirteen patients. Besides these sensory disturbances, which may be the only ones present, changes of the thermic sensation may occur. Cold may alone be less distinctly felt by the patient, or heat, on the other hand, is perhaps the sensation lost. Occasionally the various temperatures are not defined, but the loss of thermic sensibility rarely exists alone. In five of the recorded cases it was normal and in many others it is not mentioned.

If a faradaic current is passed over the cutaneous surface, or if static electricity is used, the patient

may have a burning sensation, while in thirteen cases there was a diminution of electric sensibility. The objective sensory disturbances are very rarely absent, and Pitres has shown that by slight friction it is possible to cause sensibility to reappear in the anæsthetic areas. Erb's sensory reflex was found diminished in two cases and absent in another. Compression of the femorocutaneous nerve exercised over the innominate foramen showed that it was tender in eight cases, while in ten others it was not productive of any disagreeable sensation. In one case reported by Roth the trophic and vasomotor functions were involved, because the skin of the region comprised in the process was smooth, white, and deprived of papillary projections. The surface remained pale when the patient was in a hot bath, while the remainder became red. In a case reported by Sabrazès and Cabannes the injection of pilocarpine into the diseased area and into the corresponding normal one on the other side showed the presence of trophic and vasomotor disturbances in the paræsthetic area. On the affected side, in an hour after the injection there was only slight redness, with no papillary erection or sweating. The pilomotor reflex has been found absent in two cases. On the other hand, in Lop's case the skin was of a dark red, hot, and wrinkled. The muscles underlying the paræsthetic area are usually normal, although in Joncheray's case their electric excitability was diminished, without, however, presenting the reaction of degeneration. Meralgia is ordinarily a local disease, but it has been mentioned in connection with locomotor ataxia in four cases and once in diabetes. It frequently coexists with varicose veins, hæmorrhoids, gout, or obesity. At the beginning the affection is temporary and quite limited in extent, but later, after successive attacks, it extends.

Brisard insists on the surgical treatment of this disease by resection of the affected nerve, for it must be admitted that medical treatment is of little avail. Except in slight cases the affection resists all treatment, but as the pain is not intense, the patient can get along with his infirmity. But if the pain becomes severe, resection of the nerve should be resorted to, as has been done by Chipault in two cases and in one by Mauclair. In all three the result was favorable.

In spite of the very thorough researches that have been made, it does not seem as if the ætiology of

this neuralgia, so singular in its localization, had been well demonstrated. Traumatism, cold, intoxications, etc., have been held responsible, and when these factors were lacking in the patient's history, the condition has been attributed to "arthritis" for the want of something better. For the present, however, it must be admitted that its causes are most obscure.

CHARLES GREENE CUMSTON.

THE POSSIBLE FAILURE OF THE AMERICAN MEDICAL ASSOCIATION'S INQUISITION CONCERNING PROPRIETARIES.

At this early period, in its issue for March 25th, the *Journal of the American Medical Association* contemplates the possibility of failure of the association's scheme for separating the sheep from the goats among advertisers of proprietary preparations. "On the other hand," it says, "if it all ends in a failure, we will [sic] be no worse off than we were before, and we will [sic] be richer by experience." We should like to feel that in case of failure the association would be richer in something else than experience.

A NASAL TOOTH.

An example of this curious anomaly is reported by Hecht, of Munich (*Archiv. für Laryngologie*, xvii, 1; *Berliner klinische Wochenschrift*, March 6th), in the case of a man who consulted him for a furuncle of the nostril. The tooth was distant rather more than an inch from the anterior extremity of the inferior nasal passage, and it was firmly implanted. On the opposite side there was a corresponding supernumerary tooth set obliquely in the jaw.

THE MEDICAL CORPS OF THE NAVY.

The number of newly appointed assistant surgeons who recently completed a course in the Naval Medical School seems to augur favorably as to the filling of the corps with suitable men, and the words spoken to the class by the President of the United States cannot have failed to imbue the young men with a becoming pride in their two professions, that of medicine and that of arms.

PREPUTIAL SEBACEOUS GLANDS.

Dr. Ernst Delbanco, of Hamburg (*Monatshfte für praktische Dermatologie*, xxxviii, 11; *Berliner klinische Wochenschrift*, March 6th), thinks it not uncommon to find sebaceous glands on the inner surface of the prepuce. The glands are numerous and are aggregated in the form of fine yellow grains.

News Items.

Society Meetings for the Coming Week:

MONDAY, April 3rd.—New York Academy of Sciences (Section in Biology); German Medical Society of the City of New York; Morrisania Medical Society, New York (private); Brooklyn Anatomical and Surgical Society (private); Corning, N. Y., Academy of Medicine; Utica, N. Y., Medical Library Association; Boston Society for Medical Observation; St. Albans, Vt., Medical Association (annual); Hartford, Conn., Medical Society; South Pittsburgh, Pa., Medical Society; Chicago Medical Society (annual).

TUESDAY, April 4th.—New York Neurological Society; Buffalo Academy of Medicine (Section in Surgery); Elmira, N. Y., Academy of Medicine; Ogdensburg, N. Y., Medical Association; Syracuse, N. Y., Academy of Medicine; Hudson, N. J., County Medical Society (Jersey City); Androscoggin, Me., County Medical Association (Lewiston); Baltimore Academy of Medicine; Medical Society of the University of Maryland (Baltimore).

WEDNESDAY, April 5th.—New York Academy of Medicine (Section in Public Health); New York Genitourinary Society; Harlem Medical Association of the City of New York; Society of Alumni of Bellevue Hospital; Medical Microscopical Society of Brooklyn; Medical Society of the County of Richmond, N. Y. (New Brighton); Penobscot, Me., County Medical Society (Bangor); Bridgeport, Conn., Medical Association.

THURSDAY, April 6th.—New York Academy of Medicine; Brooklyn Surgical Society; Society of Physicians of the Village of Canandaigua, N. Y.; Boston Medicopsychological Association; Obstetrical Society of Philadelphia; United States Naval Medical Society (Washington); Medical Society of City Hospital Alumni, St. Louis.

FRIDAY, April 7th.—Practitioners' Society of New York (private); Clinical Society of the New York Post-graduate Medical School and Hospital; Baltimore Clinical Society; Manhattan Clinical Society, New York.

SATURDAY, April 8th.—Obstetrical Society of Boston (private).

Change of Address.—Dr. Jean F. Chauveau, to 64 West Seventy-seventh Street, New York.

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending March 25, 1905:

	March 25.		March 18.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	379	9	383	9
Diphtheria and croup	294	38	321	34
Scarlet fever	258	13	249	25
Smallpox	1	1
Chickenpox	180	...	149	...
Tuberculosis	576	198	505	198
Typhoid fever	19	6	31	7
Cerebrospinal meningitis	167	85	135	72
	1,873	349	1,774	346

Ambulance Station for Harlem Hospital.—Plans have been filed for the erection of a three story ambulance station for the new Harlem Hospital, to be built in One Hundred and Thirty-seventh Street, east of Lenox Avenue, and for a three story and basement power station, 148 feet front and 43 feet deep, to be erected on an adjoining lot. The power station will have a hospital morgue annex.

Bequests to New York Charities.—William Vogel, the clothier, who died recently, left \$5,000 to the Mount Sinai Hospital in memory of his deceased wife, Hannah Vogel; \$1,000 to the Home for Aged and Infirm Hebrews; \$1,000 to the

Montefiore Home for Chronic Invalids; \$1,000 to Lebanon Hospital; \$1,000 to the Sanitarium for Hebrew Children, and \$1,000 to the Hebrew Benevolent Orphan Asylum Society. Mr. Vogel left a very large fortune.

House Staff Wanted at Hudson Street Hospital.—On the afternoons of April 17th and 18th there will be held a competitive examination at the Hudson Street Hospital of applicants for positions on the house staff. The term of interne extends over a period of eighteen months, and is equally divided between surgical and medical work. There will be two vacancies on July 1, 1905, and two on January 1, 1906. The opportunities to study emergency surgery are especially good at this hospital.

German Poliklinik in Need.—The German Poliklinik, 78 Seventh Street, is preparing to extend its facilities for the free treatment of the sick poor. The managers desire to acquire the building of the German Dispensary, and to meet the cost they have appealed to patrons and outside friends for funds. In a recent report it was stated that since the founding of the institution, in 1883, 1,014,682 patients have been treated, and 723,355 prescriptions have been filled by the drug store attached to the Poliklinik.

Society of the Medical Inspectors of the City of New York.—A stated meeting of this society will be held on Tuesday, April 4, 1905, at 8.30 p. m. sharp, at the Chemist's Club, 108 West Fifty-fifth Street. Order of business: Executive Session; addresses by the honorary members of the society: Dr. Thomas Darlington, Commissioner of Health; Dr. Herman M. Biggs, Medical Officer; Dr. Walter Bense, Assistant Sanitary Superintendent; Dr. John J. Cronin, Assistant Chief Inspector. Augustine C. McGuire, M. D., president; Edward M. Thompson, M. D., secretary, 315 West Fifty-eighth Street.

A Hospital for Coney Island.—The progress of this popular resort is shown by the fact that it is to have a new modern hospital that will be open the year round. The Emergency Hospital is open during the summer months, but there are many workmen employed at the different amusement enterprises during the winter, and in the case of a serious accident it is necessary that they be taken to the Norwegian Hospital, a distance of at least three miles. The Board of Estimate has authorized the condemnation of a plot of land bounded by Ocean Parkway, Coney Island Avenue, East Sixth Street, and Avenue Y for the site of the new hospital.

New Manhattan Eye and Ear Hospital.—Ground was broken for the new Manhattan Eye, Ear, and Throat Hospital building on March 23rd on the south side of Sixty-fourth Street, between Second and Third Avenues. Mrs. C. R. Agnew turned the first shovelful of earth. John Sinclair, president of the hospital, presided. Dr. Andrew H. Smith delivered an address, in which he reviewed the history of the hospital. Prayer was offered by the Reverend Dr. Stephenson, of the Fifth Avenue Presbyterian Church. The hospital is now at Park Avenue and Forty-first Street.

The new building will cover a lot from Sixty-third to Sixty-fourth Street.

Growth of the Charity Organization Society.—The growth of a new line of charitable activity is shown in the addition of a chapter to the 1905 edition of the *Charities Directory*, published by the Charity Organization Society. This new chapter gives information of organizations which send nurses to the homes of needy persons, as distinct from the nursing of the poor in hospitals, convalescent homes, fresh air cottages, and other institutions. There are 25 titles in the chapter, showing a wide variety of societies which send visiting nurses into the tenements. A large number of them are religious in character, but some of the large general societies have added visiting nurses to their staff of employees, and the department of health is sending nurses to the homes of consumptives to care for them and teach them means for preventing the spread of the disease to their families and neighbors. The Charity Organization Society movement shows a steady growth. Since the 1904 directory was published about 20 new societies have been added to the roster of such organizations in the United States, making 190 in all, and the relief societies listed in Europe and Australia now total 210. Canada has seven. The directory contains 2,000 names of societies, institutions, and other charitable organizations in Manhattan Borough, about half as many in Brooklyn, and nearly one hundred in Queens. The entries include a brief description of the work of the organization named, how and where and from whom to secure its services, and the names of officers and executive employees. The book contains 675 pages. Published by the Charity Organization Society, 105 East Twenty-second Street, New York, in cloth, at \$1.00, postpaid.

PHILADELPHIA.

Charitable Bequests.—By the will of Ann M. Sharpless, the Children's Seaside Home, at Atlantic City, N. J., receives \$2,000, and the Mercer Memorial Home, also at Atlantic City, receives \$2,500.

Baltimore Ophthalmological Society.—Dr. William Campbell Posey, of Philadelphia, read a paper before the Baltimore Ophthalmological Society on Friday night, March 24th, on Some Ophthalmological Phases of Diseases of the Accessory Sinuses of the Nose.

Changes in the Philadelphia General Hospital Staff.—Dr. Charles A. Hatfield has resigned as assistant physician, department for tuberculosis. Dr. Ward Brinton has been appointed assistant physician, department for tuberculosis. Dr. Samuel Rhodes has been appointed registrar of the department for tuberculosis.

Scientific Society Meetings for the Week Ending April 8, 1905.—Monday, April 3rd, Philadelphia Academy of Surgery; Biological and Microscopical Section, Academy of Natural Sciences; Society of Normal and Pathological Physiology, University of Pennsylvania. Tuesday, April 4th, Academy of Natural Sciences. Wednesday, April 5th, College of Physicians; Association of Clin-

ical Assistants of Wills's Hospital. Thursday, April 6th, Obstetrical Society; Medical Society of the Southern Dispensary. Friday, April 7th, American Philosophical Society.

Philadelphia Polyclinic.—The following is a report of the work at the Philadelphia Polyclinic and College for Graduates in Medicine for February, 1905: Patients admitted to house, 102; patients discharged, 93; new patients treated in dispensary, 1,539; total visits to dispensary, 7,642; accident ward, 527.

Deaths.—Dr. Samuel B. Hoppin died on March 21, 1905, at his home, 247 South Forty-fourth Street, aged 86 years. Dr. Hoppin was born in Providence, R. I., in 1818, and graduated from the Jefferson Medical College in 1852. He was a surgeon in the navy during the civil war, and about thirty years ago was made registration physician in the prothonotary's office.

Dr. William C. Detwiler died at Easton, Pa., on March 23rd. He was the oldest practising dentist in Easton.

Pharmaceutical Matters.—At the meeting of the Pharmaceutical Association, held March 21st, Dr. Joseph P. Remington announced that the Governor of Pennsylvania would in all probability sign the bill for further regulating the practice of pharmacy. The bill provides that all persons applying for certificates of registration as competent pharmacists must be graduates of a reputable college of pharmacy. Professor Henry P. Hynson, of the University of Maryland, spoke upon Ethical Pharmaceutical Practice and Its Recompense. Dr. William C. Alpers spoke on Professionalism *versus* Commercialism in Pharmacy. Mr. George M. Beringer spoke on The Evolution of Nostrum Vending and Its Relation to the Practice of Medicine and Pharmacy.

Bill to Permit the Castration of Hopeless Imbeciles.—The legislature of the State of Pennsylvania passed a bill on March 21st, by 105 yeas to 28 noes, providing that it shall be compulsory for institutions in the State, interested exclusively or especially with the care of idiots and imbecile children, to appoint upon their staffs at least one skilled neurologist and one skilled surgeon of recognized ability, whose duty it shall be, in conjunction with the chief physician of the institution, to examine the mental and physical condition of the inmates. If in their judgment deemed advisable, it shall be lawful for the surgeon to perform such operation as shall be decided safest and most effective to prevent procreation. The operation shall not be performed except in cases that have been pronounced non-improvable after one year's residence in the institution.

Bulletin of the Ayer Laboratory.—The second number of the bulletin of the Ayer Clinical Laboratory of the Pennsylvania Hospital has just been received. It contains the following contributions: A Study of the Bone Marrow in Typhoid Fever and Other Autoinfections, by Dr. Warfield T. Longcope; Studies on the Basophilic Granulations of the Erythrocytes in Lead Poisoning and Other Conditions, with Special Reference

to the Relation Which They Bear to the Nuclei of the Red Blood Corpuscles, by Dr. Williams B. Cadwallader; The Relation Between Congenital Malformations of the Heart and Acute Endocarditis, with Report of Two Cases, by Dr. G. Canby Robinson; The Report of a Case of Malignant Tumor of the Testicle Resembling Chorioepithelioma, with Metastases, by Dr. J. A. Scott and Dr. Warfield T. Longcope. The fasciculus contains some excellent illustrations.

Vaccination in Parochial Schools.—As a result of a conference between the bureau of health and the authorities of the Roman Catholic Church in Philadelphia, Archbishop Ryan agreed to place the parochial schools of Philadelphia under the jurisdiction of the bureau of health, in so far as relates to the matter of vaccination. In future no child who has not been successfully vaccinated will be admitted to the parochial schools, and all unprotected children found by the medical inspectors in those schools will be excluded until the operation has been performed. Since the beginning of the inspection of these schools 1,775 children have been discovered who either never have been vaccinated or whose vaccination scars were of doubtful protective value. These children have all been vaccinated and permitted to return to school.

The Health of the City.—During the week ending March 18, 1905, the following cases of transmissible diseases were reported to the bureau of health:

	Cases.	Deaths.
Typhoid fever.....	247	19
Scarlet fever.....	49	2
Chickenpox.....	50	0
Diphtheria.....	60	11
Cerebrospinal meningitis.....	5	2
Measles.....	27	2
Whooping cough.....	6	0
Tuberculosis of the lungs.....	66	68
Pneumonia.....	70	75
Erysipelas.....	9	1
Tetanus.....	1	0

The total mortality was 589, in an estimated population of 1,438,318, corresponding to an annual death rate of 21.39 per 1,000 population. The total infant mortality was 142; 120 under one year, 22 between one and two years. There were 41 still births; 26 males and 15 females. The following deaths from other transmissible diseases were recorded: Tuberculosis, other than tuberculosis of the lungs, 7; puerperal fever, 5; dysentery, 1; diarrhoea and enteritis under two years, 30. The weather has been mild with no rain. The increase in the number of cases of typhoid is marked; 247 this week against 178 for the week ending March 11th. The great increase comes from the nineteenth, twenty-fifth, thirty-first, and thirty-third wards, none of which is supplied with filtered water. These four wards furnished 155 of the new cases. From the districts wholly (twenty-first and twenty-second wards), or partially (twenty-fourth and twenty-seventh wards) supplied with filtered water, only ten cases were reported.

Smallpox in Philadelphia.—We copy the following facts about smallpox from the bulletin of the bureau of health for March 4, 1905: The last case of smallpox was reported on December 17, 1904. During the past four years about 1,000

medical students, 100 nurses, 60 physicians, and over 100 servants were freely exposed to smallpox in the wards of the Municipal Hospital. Of this group only one contracted the disease. This individual, a medical student, descended from an antivaccination family, through purposeful deception gained access to the smallpox wards, contracted the disease and was seriously ill. During the year, of the unvaccinated patients treated in the wards of this institution, 32.73 per cent. died; of those vaccinated in infancy, but who had one good mark, 3.81 per cent. died; of those vaccinated in infancy who had one fair mark, 8.13 per cent. died; and of those vaccinated in infancy who had one poor mark, 11.25 per cent. died.

Section in Medical History, College of Physicians.—The section in medical history of the College of Physicians of Philadelphia has been organized, its officers elected, its executive committee appointed by the president of the college, and its first meeting arranged for April 24th, which is the fourth Monday of the month. Meetings will be held regularly, at which papers will be read; interesting books and manuscripts will be shown; lantern slide lectures will be held; distinguished medical historians will be invited from other cities to address the section, and it is hoped and expected that in Philadelphia, the richest city in medical historical material in the country, there can be aroused an interest which will lead to the production of a great deal of exceedingly important writing and interesting discussion on such matters.

The following are the officers of the newly organized section: Chairman, Dr. R. G. Curtin; clerk, Dr. William Pepper; executive committee, Dr. F. R. Packard, Dr. C. A. Oliver, and Dr. S. McC. Hamill.

GENERAL.

Yale College, Chungsha, China.—Dr. Edward H. Hume, a graduate of the medical school of the Johns Hopkins University, Baltimore, has been appointed head of the medical department of the new Yale College in Chungsha, China.

The Louisville Medical and Surgical Society held its annual banquet and election of officers at the Galt House, Louisville, Ky., on March 20th. Dr. W. H. Coleman was elected president; Dr. C. W. Hibbitt, vice-president; Dr. J. K. Norris, secretary; and Dr. Dunning S. Wilson, treasurer.

Chelsea, Mass., Naval Hospital.—Medical Director Howard Wells, United States Navy, who, since October 2, 1903, has been in charge of the Naval Hospital at Narragansett Bay, R. I., has taken charge of the United States Naval Hospital at Chelsea. He relieves Medical Director Dwight Dickinson, who has been in charge since October 15, 1901, and who goes to Portsmouth to serve in the same capacity.

Bequest to Bloomington, Ill., Hospital.—The uncertainty that has marked the division of the vast estate of Abram Brokaw, the eccentric millionaire, is cleared up partially by the announcement that he has left the Brokaw Hospital in this city \$100,000, farms worth \$50,000, and had re-

leased it from debts amounting to \$15,000, bringing his total donation to this institution up to \$200,000.

A Nurse Justly Rewarded.—It is reported that Mrs. Alida Gray, a young nurse at the Middletown, N. Y., State Hospital, has received a legacy of \$40,000 from a former patient of the hospital who felt grateful for the care and attention given. Neither Mrs. Gray nor the benefactor's attorney will divulge the name of the testator.

Kentucky Physician Nominated for the Hall of Fame.—The Henderson County, Ky., Medical Society, at a meeting recently held, determined to present the name of Dr. Ephraim McDowell, one of Kentucky's illustrious sons and one of the most famous of American physicians, for one of the statues in the National Hall of Fame. It was determined to request the State Medical Society and the *Kentucky Medical Journal* to use their influence toward the desired end.

A Testimonial to Dr. Matas, of New Orleans.—An event of unusual interest was celebrated at the residence of Dr. Rudolph Matas, No. 2255 St. Charles Avenue, New Orleans, on the evening of March 19th, when a body of physicians, professors, and students and intimate friends called at the Matas home and presented him with a beautiful silver service, consisting of some 125 pieces, and a handsome silver loving cup. These tokens of honor and esteem were presented to Dr. Matas on the twenty-fifth anniversary of his graduation from Tulane Medical School and his entering upon the active practice of medicine. The affair was a complete surprise. Dr. Matas was spending a quiet Sunday evening at home, when at 8 o'clock the bell rang, and a host of friends walked in. Dr. Stanford E. Chaille, Dean of the Medical College, made the presentation. Dr. I. L. Leucht, Rabbi of Touro Synagogue, seconded the presentation of Dr. Chaille, and Dr. Matas responded in words of tenderest appreciation. He was so overcome that he spoke with difficulty at the beginning of his remarks. The large chest of silver rested on a table under the folding doors of the parlor while the presentation was being made. The loving cup, also of a most beautiful design and creation, rested on a stand several inches high.

The Milk Question in Chicago.—The milk situation is very satisfactory at an unsatisfactory season. Of the 820 samples of milk and cream analyzed in the laboratory during the week only 14 of milk and 30 of cream were found below grade, a proportion of 5.8 per cent. This is 1 per cent. better than the yearly average of 1904 and at the most unfavorable season of the year. The director of the laboratory reports that the solitary dairy inspector notified the department that a number of shippers at Hinsdale, Downer's Grove, and Lisle, Ill., were feeding wet malt and refused to comply with the department's regulations. As a result of this notification inspectors were sent to the railway receiving platforms with orders to return all slop and malt fed milk to the shipper. They returned 89 cans in one day to the

stations named. These shippers then sent their milk to a creamery in Lisle and upon learning this the department rejected all milk and cream from this creamery until every shipper who supplied the creamery with milk had placed his affidavit on file in the laboratory that he would not feed malt or brewery slops to his milch cows. As a result of this action the creamery and the department have arrived at an agreement with the railroad, by which the company agrees not to ship any more malt to these towns. Wet malt and brewery slops milk will soon be unknown in Chicago.

Statement of Mortality in Chicago for the Week Ending March 25, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's estimated midyear populations of 1,990,750 for 1905 and of 1,932,315 for 1904:

	Mar. 25, 1905.	Mar. 18, 1905.	Mar. 26, 1904.
Total deaths, all causes.....	581	557	626
Annual death rate per 1,000.....	15.21	14.57	16.93
By sexes—			
Males.....	322	324	382
Females.....	259	233	244
By ages—			
Under 1 year.....	126	133	107
Between 1 and 5 years.....	58	51	39
Over 60 years.....	109	98	138
Important causes of death—			
Acute intestinal diseases.....	24	27	31
Apoplexy.....	12	15	17
Bright's disease.....	37	34	42
Bronchitis.....	22	31	18
Consumption.....	81	63	76
Cancer.....	27	22	25
Convulsions.....	16	14	10
Diphtheria.....	4	11	9
Heart disease.....	37	42	50
Influenza.....	6	2	4
Measles.....	2	8	1
Nervous diseases.....	22	17	22
Pneumonia.....	106	103	156
Scarlet fever.....	0	2	1
Smallpox.....	2	3	0
Suicide.....	7	11	11
Typhoid fever.....	5	4	8
Violence (other than suicide).....	25	20	25
Whooping cough.....	9	11	0
All other causes.....	132	108	120

Smallpox continues to pick out the non-vaccinated with unerring certainty. Of the 22 new cases sent to the Isolation Hospital during the week none had ever been revaccinated since early childhood and 17 had never been vaccinated at all. Of the 5 who had been once vaccinated in childhood the youngest was 26 years old; four of the non-vaccinated were children under the school age of 6 years. Since the beginning of the year 232 cases of the disease have been discovered and removed to a hospital; of these, 34, or 14.6 per cent., died; 108 were discharged, recovered; 90 remain under treatment. The record is a sad commentary upon the criminal folly of those who neglect vaccination.

The Osteopathic Bill Favorably Reported by the Senate Committee on Judiciary at Albany.—Objections to this bill have been summarized as follows:

First. Osteopathy, so called, is an agent or method used in the treatment of disease, and is included in the general practice of medicine.

Second. Osteopathy should not be made a special branch of medicine, by an act of the legislature, but should come under the present State laws, which govern all the special branches as well as the general practice of medicine. Any licensed physician has now the right to practice osteopathy as a specialty.

Third. The legislature should protect the public by denying the endorsement of the State to any person, as being capable of treating the diseases of the human body, unless such person can make a diagnosis of the condition of the human body, to do which requires a full knowledge of the science of medicine as taught in the medical colleges of this State, including the use of drugs and other valuable therapeutic agents.

Fourth. If the so called osteopathic bill becomes a law all candidates who fail to pass the Regents' examinations to obtain a license to practice medicine in this State may in this State treat all diseases of the human body by holding a diploma from any regular osteopathic college in the United States, a privilege which would lower the standing of this State in the educational world.

And finally it would be more reasonable for the legislature to separate the special branches of criminal, corporation, and real estate law from the general practice of law and establish for each of them a special examining board, so as to make it easier for the candidates for admission to the bar who desired to practice as specialists, than it would be for the legislature to select one special therapeutic agent used in the treatment of disease and separate it from the general practice of medicine as a panacea for all diseases at the request of those enthusiasts who now ask for a special osteopathic examining board.

Appointment at the Government Hospital for the Insane.—The United States Civil Service Commission announces an examination on April 26 and 27, 1905, to secure eligibles from which to make certification to fill a vacancy in the position of physician (female) in the Government Hospital for the Insane, Washington, D. C., at \$1,500 per annum and quarters, and vacancies as they may occur in any branch of the service requiring similar qualifications. Only unmarried women will be admitted to this examination. The examination will consist of the subjects mentioned below, weighted as indicated:

Subjects.	Weights.
1. Letter writing (a letter of not less than 150 words on one of two subjects given).....	5
2. Anatomy and physiology.....	5
3. Chemistry, materia medica, and therapeutics.....	10
4. Bacteriology and hygiene.....	10
5. Surgery and surgical pathology.....	15
6. Obstetrics and gynecology.....	15
7. Mental diseases.....	20
8. Experience (rated on application).....	20
Total.....	100

Applications will be received from graduates of recognized medical schools. Credit will be given for experience obtained in a professional capacity in institutions for the care of mental diseases, in general hospitals, and in the actual performance of surgical operations and the care of operative cases. Two days will be required for this examination. Age limit, 25 to 40 years on the date of the examination. This examination is open to all citizens of the United States who comply with the requirements. Applicants should at once apply to the United States Civil Service Commission, Washington, D. C., for application Form 1312. No application will be accepted unless properly executed and filed with the commission at Washington. As examination papers are shipped direct from the commission to the places of examination, it is necessary that applications be received in ample time to arrange for the examination desired at the place indicated by the applicant. The commission will, therefore, arrange to examine any applicant whose application is received in time to permit the shipment of the necessary papers.

Pith of Current Literature

PRESSE MEDICALE.

February 25, 1905.

1. Radium and Radiotherapy, By P. DESFOSSES.
2. General Results Obtained by Bronchoœsophagoscopy; Advance Gained by This Method, By J. GUISEZ.

1. **Radium and Radiotherapy.**—Desfosses says of the radium rays that they propagate themselves in straight lines and cannot be reflected, refracted, or polarized. He describes them as of a much more complex nature than the Röntgen rays. The apparatus employed in their use is described, its faults are pointed out and the present state of our knowledge as to its therapy is considered.

2. **Bronchoœsophagoscopy.**—Guisez presents illustrations of the instruments employed in this work, describes the technics of their use, and indicates the unquestionable advantages of this method of diagnosis in certain classes of cases.

March 1, 1905.

1. The Bacillus of Koch and the Blood of the Tuberculous, By ANDRÉ BERGERON.
2. Abscess of the Abdominal Wall Due to Migration of Entozoa, By PIERRE SIKORA.

1. **Koch's Bacillus and the Blood of the Tuberculous.**—Bergeron finds as the result of a number of experiments that the bacillus of Koch does not habitually sojourn or proliferate in the blood, but that the bacilli when introduced directly into the circulation quickly fix themselves in the tissues and disappear from the blood.

2. **Abscess of the Abdominal Wall.**—Sikora relates the case of a woman, 63 years old, who had suffered long from lumbrici. A soft, round, reducible tumor appeared in the median line of the abdomen above the umbilicus. It was not very tender on pressure and was diagnosed as hernia. The general health began to fail and four months later the tumor was found to be very large, fluctuating, and irreducible, with the superjacent skin reddened. The abscess was opened and found to contain many lumbrici.

SEMAINE MEDICALE.

February 22, 1905.

Ascending Neuritis Following Appendicitis,

By F. RAYMOND and G. GUILLAIN.

Ascending Neuritis Following Appendicitis.

Raymond and Guillaïn report the case of a man who was attacked by appendicitis in May, 1903, and confined to bed for three or four weeks. Five or six hours after the commencement of the appendicitis the patient began to suffer violent pain in the right thigh. This pain continued with paroxysmal exacerbations and presented the characteristics of a crural neuralgia. The neuralgia improved along with the appendicitis, but intermittent pains persisted in the crural region until September, when a second attack of appendicitis was accompanied by an attack of sciatic neuralgia. All of the symptoms again improved. A third attack of appendicitis in February, 1904, was accompanied by an extension of the neuralgic pain to the calf of the leg and a sensation of ting-

ling in the foot. After recovery from this attack the patient had some difficulty in lifting the foot and walked with some lameness. Another attack of appendicitis in August was accompanied by an exacerbation of the pains in the regions supplied by the right crural and sciatic nerves and the extension of the pain to the region supplied by the left sciatic nerve. The appendix was removed September 19th. It was in a retrocæcal position, bound down by adhesions. After the operation the pains in the lower limbs continued and the paresis of the extensor muscles increased until the final condition was one of paralysis and muscular atrophy with the right foot in a state of pes equinus. The writers think that all this was the result of an ascending neuritis which was started by the inflammation of the appendix.

ZENTRALBLATT FUER INNERE MEDIZIN.

January 28, 1905.

1. Metaphenyldiamin in Diarrhœa, By B. BOYE.

1. **Metaphenyldiamin.**—Boye says that this drug, known as lentin, is valuable in the diarrhœas of infants and of older nurslings. The dose for children is one tenth of a grain one or more times daily, for adults one and one half to four and one half grains three times daily. The author has observed that patients with diarrhœa taking the drug have darkened urine, but healthy persons do not show this reaction.

BERLINER KLINISCHE WOCHENSCHRIFT.

February 13, 1905.

1. Abuse of Tendon Transplantation, By H. OPPENHEIM.
2. Disinfectant Action of Griserin (*To be concluded*), By E. FRIEDBERGER and W. OETTINGER.
3. A Case of Keratomycosis Aspergillina, By OSTERHOIT.
4. Palpation of the Appendix and Larvate Appendicitis, By T. HAUSMANN.
5. Osteomyelitis in Nurslings, By H. MOHR.
6. Physical Methods of Cardiac Diagnosis, By DE LA CAMP.

1. **Abuse of Tendon Transplantation.**—Oppenheim reports in detail three cases seen by him after operation in which tendon transplantation had been done in the hope of improving paresis of muscles. The patients suffered respectively from progressive muscular atrophy, chronic anterior poliomyelitis and compression of the lumbosacral cord by a tumor. Oppenheim urges that the operation be restricted to its proper field and be not employed in progressive diseases of this character.

4. **Palpation of the Appendix.**—Hausmann says that in some individuals the vermiform appendix can be most easily palpated by having the patient raise the right leg in an extended position, thus putting the psoas on the stretch. The author thinks it important that to palpate the appendix accurately, the other portions of the intestinal canal be correctly mapped out. He gives full details as to the accomplishment of this purpose. He speaks of sixteen cases of larvate appendicitis which he has diagnosed. Hausmann says he is not yet fully convinced of the diagnostic value of sensitive-ness over McBurney's point.

5. **Osteomyelitis Among Nurslings.**—Mohr

describes two such cases, giving minute accounts of the etiology, the incidence and the clinical course of the disease. In his first case there was a sclerotic osteomyelitis which was cured without functional disturbance. In the second case the functional result was good also, although the disease involved the hip joint and the epiphysal line of the femur.

6. Cardiac Diagnosis.—De La Camp says the exact determination of the size of the heart is indispensable to a conclusion as to its function. He speaks of the newer methods of palpation and percussion for the determination of relative heart dulness. In some cases, orthodiagraphic pictures proved serviceable.

FORTSCHRITTE DER MEDIZIN.

February 1, 1905

Cryoscopy of Transudates and Exudates.

By SCHOENBORN.

Cryoscopy of Transudates and Exudates.—Schoenborn's investigations included the study by this method of 20 cases of pleural and abdominal transudates and exudates, none of them being purulent. The cases were under observation for months, before and after the fluid was withdrawn by puncture. Control experiments were performed by radioscopy in many of the cases of pleural deposit. The following conclusions were reached: 1. If the effusion was hypotonic, that is less concentrated than the blood serum, spontaneous absorption resulted in three fifths of the cases; 2, in isotonic effusions the same result occurred; 3, in hypertonic effusion there was absorption in only one fifth of the cases; 4, no particular difference was observed between transudates and exudates as to the degree of their concentration.

1. The Results of Attempts to Produce Immunity from Insanity by Pasteur's Method, By BEINSTEIN.
2. The Early Diagnosis of Pregnancy, By PISKACEK.
3. Tubal Pregnancy with Coexisting Pyosalpinx,

By HITSCHMANN.

2. The Early Diagnosis of Pregnancy.—Piskacek observes that the signs of pregnancy which pertain to the fetus, the fetal heart sounds, the bruit of the umbilical cord, the determination of the various parts of the fetus, and the fetal movements are available only after pregnancy is far advanced. The signs which indicate the probability of pregnancy, the cessation of the menses, the enlargement of the uterus, the violet color of the mucous membrane of the vulva and vagina, the changes in the breasts, and the changes in the general condition; these signs, when taken individually, do not infallibly indicate that condition, or even when they are combined, though in the latter instance the probability is very near to certainty. These facts lend additional interest and importance to the early diagnosis of pregnancy, and the signs of that condition which relate to the sense of touch acquire especial significance. Hegar's sign is first cited, which consists in a softness and compressibility of the lower uterine segment, and can be demonstrated in about half the cases of pregnancy. Landau's sign, compressibility of the uterus at the tubouterine junction,

is less frequently demonstrable. Another sign described by Hegar is the fold in the anterior uterine wall, caused by the contraction of the uterine muscle. This sign should not be too persistently sought, as it may be the means of effecting an abortion. Several writers have described as an early change in the uterus an asymmetrical form of the organ which is most conspicuous at the uterotubal junction. It is most frequently observed in primipare, on both anterior and posterior uterine walls, and with it is associated a decided softness of the organ. Braun has observed at the border of the organ a furrow which is analogous to the compressibility described by Hegar. In the asymmetrical pregnant uterus there are usually pain and sensitiveness at the asymmetrical portion. Most of these conditions which are determined by touch are discoverable at the fifth week; they are seldom present at an earlier period. After the fourth lunar month the uterus assumes an ovoid form and thenceforward develops symmetrically. If these signs which have been specified are absent pregnancy can be excluded almost with certainty.

3. Tubal Pregnancy and Coexistent Pyosalpinx.—Hitschmann observes that it has long been recognized that there is a relationship between chronic inflammatory processes and tubal pregnancy, but it has been generally supposed that acute purulent inflammations would effectually prevent the nidation of the ovum in the tube. A careful serial examination of a pregnant tube showed, however, that suppurative inflammation in the latter neither prevented nidation nor the subsequent nourishment of the ovum. Such a condition must be rare, however, for there is in connection with gonorrhœal inflammation of the tube a toxic element which would usually be destructive of the life of the ovum. The course which the spermatozoa would take in the presence of an acute suppurative inflammation of the tube has not yet been determined. The genesis of tubal pregnancy, according to this author, is to be referred rather to the nature of the ovum than to the conditions of the maternal tissue. Recent studies have shown that the ovum follows a definite course in a definite time, and that it can become implanted in one of the furrows of the tubal mucous membrane only at a particular stage of its development. If this condition fails it passes on to the uterus, and is there implanted, or passes out from the organ.

1. On the Surgical Treatment of Affections of the Biliary Ducts (*To be concluded*), By M. M. KOZNETSOFF.
2. A Case of Ankylostomiasis, By A. A. KARSHINE.
3. Local Anæsthesia by Means of Cocaine and Adrenalin, By I. S. PILETSKI.
4. The Treatment of Morphine Habitués, Alcoholics, and Smokers by Means of Hypnotism (*To be concluded*), By M. I. BEREZNIISKI.

2. Ankylostomiasis.—Karshine's case occurred in a boy aged eleven years, who had lived at Port Arthur until the war broke out, when he was taken to Irkutsk (Siberia). The boy was accustomed to

play in the sand at Port Arthur. His blood showed a marked eosinophilia, and the presence of parasites in the intestines was suspected. *Tænia saginata* was then found in his feces, and he improved after this parasite had been removed with the aid of the usual anthelmintics. The anæmia, however, did not abate, and ankylostoma was finally found. The treatment consisted chiefly in the use of thymol in repeated doses. The author thinks that the infection in this case came from a Japanese, Chinese, or Korean source, and fears that the Russian troops will be infected in the course of their campaigns which involve a great deal of digging. These soldiers, he thinks, may carry the infection to European Russia, where the disease is very rare indeed.

3. Cocaine and Adrenalin Anæsthesia.—Piletski recommends the use of a one half per cent. solution of cocaine for local anæsthesia, with the addition of two drops of the 1:1000 solution of adrenalin chloride to the c. c. of the cocaine solution. This combination acts both as an anæsthetic and a hæmostatic, and excellent results were obtained with it in a large number of cases. The adrenalin tends to counteract the depressant effects of the cocaine. Comparatively large amounts of the solution can be used, as the strength of it is not great, and the author thinks that it is far better to use a weak solution and a considerable amount of it in producing local anæsthesia. Both the methods of Reclus and of Schleich may be used with the mixture mentioned in this paper.

7. Clinical Examination of the Urine. A Critical Study of the Commoner Methods (*Concluded*), By RICHARD C. CABOT.
8. Idiopathic Epilepsy. Observations on Its Treatment, By DANIEL R. BROWER.
9. Immunity. Chapter IX.

1. Tuberculosis.—Bridge pleads for common sense in the treatment of pulmonary tuberculosis. Cure can only come through increased body resistance, and this can only be obtained at present through good food and proper modes of life.

3. X Ray.—Stover advocates taking two x ray pictures of every injury and foreign body. These pictures should be taken from different,

but symmetrically placed, points. Then by placing the negatives or positives in a properly constructed stereoscope, an image with three dimensions will be seen and the foreign body or injury can be accurately studied. The article is illustrated.

4. See this *Journal*, Vol. LXXX, page 232.

5. Museum in Medical Teaching.—Abbott is the curator of the pathological museum at McGill. She shows: (1) The important place a museum should and can fill in medical teaching; (2) how a well organized and well classified museum evolves itself as a teaching mechanism of great value; (3) how the system she advocates has worked at McGill University.

7. Examination of the Urine.—Cabot concludes in this number a very elaborate paper. It should prove of the greatest value to all those who systematically avail themselves of laboratory methods. It will go considerably over the heads of those who are in the habit of depending on the ordinary textbooks of medicine for their knowledge of pathological states of the urine. The author concludes: " (1) There are many cases of acute glomerular nephritis which cannot be recognized by any of the methods of examination known to us. (2) In some cases of subacute and chronic glomerular nephritis, our diagnostic resources are likewise at fault, but, in the great majority of cases here studied, the condition of the urine, taken in connection with other features of the clinical picture, enabled us to anticipate the autopsy findings. Our success in the diagnosis of chronic glomerular nephritis is almost as constant as our failure in the acute cases. (3) When we face the group of chronic interstitial cases, our diagnostic resources appear to be neither as sufficient as in chronic glomerular nephritis, nor as inadequate as they were shown to be in the acute cases. In about one third of the cases the diagnosis was correctly made before death. (4) Among other conditions mistaken for nephritis, owing to the implicit reliance in the urinary findings, we find that the senile and arteriosclerotic degenerations are not infrequently the cause of mistaken diagnoses of chronic nephritis, while in conditions involving passive congestion or acute degeneration of the kidney, the urine occasionally simulates that of acute nephritis. Even in cases where no lesions are to be found at autopsy, the urine is occasionally highly albuminous and full of casts. (5) In our ordinary urinary examinations, common errors are: (a) The attempt to estimate urea without any accurate knowledge of the patient's metabolism. (b) The statement that renal cells are present when all that we know is that we have seen small mononuclear cells, perhaps belonging to the renal tubules, perhaps not. (6) Cryoscopy and other attempts to test more directly the renal permeability are not as yet capable of supplementing in clinical work the older methods of examination in the diagnosis of nephritis. The vast majority of estimations of urinary solids, including urea, are in my opinion a waste of time, since they are not, and in most

cases cannot be made, part of a general metabolism experiment. The attempt to estimate the anatomical condition of the kidney by the measurement of albumin and the search for casts is fallacious in the extreme. The most reliable data about the urine are those most simply and quickly obtained, the twenty-four hour quantity, the specific gravity, and the color.

The Treatment of Appendicitis.

(a) Can We Wait for Localization when the General Peritoneal Cavity is Involved? By C. A. PORTER.

(b) Remarks on Appendicitis,

By MAURICE H. RICHARDSON.

(c) Some Observations on Appendicitis,

By R. H. FITZ.

(d) Choice of Method of Opening the Abdomen in Appendicitis, By FRANCIS B. HARRINGTON.

(e) Subphrenic Abscess as a Complication of Appendicitis, By HERBERT L. BURRELL.

(f) Immediate Operation vs. Delay in Acute Appendicitis, By G. W. W. BREWSTER.

(g) The Bacteriology of General Peritonitis,

By THOMAS J. MANAHAN.

(h) The Results of Operative Treatment of General Peritonitis Following Appendicitis, at the Massachusetts General Hospital, during the Past Five Years,

By WILLIAM C. QUINBY.

Appendicitis.—(a) *Can We Wait for Localization?* Porter is an advocate of immediate operation in practically all cases of acute appendicitis. His paper ends with sixteen formal conclusions, some of which qualify the advice to operate at once in all cases. Part of the author's advice follows: (1) Purgatives should never be given in acute appendicitis before operation. (2) Ochsner's treatment is the best treatment to adopt from the outset of an attack and to persist in when operation is refused. (3) It is the best postoperative treatment in almost all cases. (4) Until the superiority of conservative treatment has been demonstrated beyond question the majority of surgeons will continue to advocate immediate operation in most cases of acute appendicitis. (5) Ochsner's treatment should be advised in most cases of spreading or diffuse peritonitis when a reasonably good surgeon cannot be obtained. (b) *General Remarks.* Richardson begins his paper with a brief description of his method of incision, of what he considers the indication for peritoneal drainage, and of the indications for operative intervention. The author holds that the sooner a patient is operated upon the surer he is to recover. The rule to operate at once has some exceptions: (1) Serious affections of the heart, lungs, kidneys, etc., may demand delay. (2) Cases in which the diagnosis admits of some doubt. (3) In recurring appendicitis, it is at times best to wait and do an interval operation. The paper ends with a general review of the authors' work in this line of surgery. (c) *Observations.* Fitz, being an internist, believes in operating only when an operation is called for. If this is not done a large number of unnecessary operations will be performed, since

many attacks of appendicitis end spontaneously and recurrent attacks are far from being the rule. (e) *Subphrenic Abscess.* Burrell quotes Christian's and Lehr's statistics, which show that a subphrenic abscess may be expected in from eight to ten per cent. of all fatal cases of appendicitis. Reference to nine cases in which the diagnosis was made during life are given. Six of these patients died and three recovered. (f) *Immediate Operations.* Brewster concludes: (1) Delay is indicated in mild cases in which there is no doubt about the recovery without operation. (2) Immediate operation is indicated in all other cases of acute appendicitis.

1. Is the Common House Fly a Factor in the Spread of Tuberculosis? By J. O. COBB.

2. A Case of Extensive Carcinoma of Tongue and Neck, Presenting Points of Special Interest,

By WILLIAM SEAMAN BAINBRIDGE.

3. A Dissertation on Temperament, Diathesis, Dyscrasia, Predisposition, Cachexia, Susceptibility, Idiosyncrasy, and Heredity (*To be concluded*),

By HOMER WAKEFIELD.

4. Methods Employed in the Examination of Milk by City Health Authorities, By A. H. STEWART.

5. The Non Sequitur in Medicine,

By HENRY A. FAIRBAIRN.

6. The Delirium and Hallucinations of Digitalis,

By H. O. HALL.

7. Society for Experimental Biology and Medicine,

By WILLIAM J. GIES.

1. **The Spread of Tuberculosis.**—Cobb asserts that most of the great investigators believe, though they cannot prove, that tuberculosis gains entrance to the human body through the alimentary canal. He holds this view himself. It has been shown that flies are capable of carrying, not only on their feet, but in their intestinal canals, active, virulent bacilli of various kinds. Hayward and Hoffman have proved that the bowel movements of flies that have fed on tuberculous sputum contain active tubercle bacilli. The author notes the avidity with which flies eat sputum and also the ubiquity of flies in fly time. The author concludes that flies are the great spreaders of consumption.

2. **Carcinoma of the Tongue.**—Bainbridge reports the following case: Man, aged forty-nine years, suffering from carcinoma of the tongue for about one year. X ray treatment for nine weeks. No improvement. Finally operation in two stages. (1) Incision, horseshoe shaped, from tip of one mastoid to tip of the other, and extending downward as far as the thyroid. A second incision was made along the anterior border of the left sternomastoid. Through these two incisions both lingual arteries were tied, and the glands in the floor of the mouth and all those involved in the neck were extirpated. Wound healed by first intention. (2) Seventeen days later excision of the tongue. To do this the mouth was widened on the left side. The patient made a good recovery, and is well at the present time.

4. Examination of Milk.—Stewart describes a centrifuge in which twenty milk tubes can be sedimented at once. This machine is used as a matter of routine by the Philadelphia health board. The method of making tests follows: Milk is sedimented and a smear is made with the sediment. This is stained with Jenner's stain, and the number of bacteria, red blood cells, and white blood cells per cubic centimetre are estimated. If a specimen shows 100,000 or more cells per cubic centimetre it means that the cow from which the milk came has diseased udders or teats. The particular dairy from which the milk came is at once notified and the sick cow excluded. This method of guarding the purity of the milk supply is said to give very good satisfaction, both to the health authorities and to the dairymen.

6. Digitalis.—Hall for the second time calls attention to the fact that digitalis, even at times in small doses, is capable of causing delirium and hallucinations. This observation has been made in France, and in this country Babcock has endorsed the author's claims. Probably it not infrequently happens that the delirium or hallucinations of digitalis or other powerful heart stimulants is mistaken for a symptom of the disease under treatment.

MEDICAL NEWS.

March 25, 1905.

1. Roof Gardens on City Private Houses,
By W. P. NORTHRUP.
2. Fifteen Years' Experience in the Treatment of Typhoid
Fever at the Roosevelt Hospital,
By WILLIAM HANNA THOMSON.
3. Clinical Studies in Blood Pressure and Shock in Trau-
matic Surgery, By JONATHAN M. WAINWRIGHT.
4. The Purpose of Eyeglasses, By ELLICE M. ALGER.
5. The Treatment of Chronic Empyema of the Antrum,
both Simple and When Combined with Empyema
of the Ethmoid and Sphenoid,
By R. BISHOP CANFIELD.

1. Roof Gardens.—Northrup calls attention to how easy it is to convert part of the roof of a city house into a suitable playground for young children. He illustrates such a roof garden built by a friend of his. The size is twenty-four by twenty-four feet, the cost was about one hundred and fifty dollars. The physical benefit to the children for which the roof was arranged is beyond calculation. From anæmic, listless, and well behaved darlings they have developed into red cheeked and lusty little savages.

2. Typhoid Fever.—Thomson asserts that it is stated in England, by recognized authorities, that the treatment of typhoid fever has made no advances in the last fifty years, and that the present mortality of the disease is practically what it used to be, i. e., 18.5 per cent. Such a statement cannot be made of typhoid in this country. The author's total mortality for the past fifteen years has been 7.05 per cent. (total cases, 574). He holds that if patients could be placed under treatment during the first week the mortality should not exceed three per cent. The author

compares the description of a typical case of typhoid as given in Bristow's textbook of forty years ago, with the clinical history of a typical case as seen at present under good treatment. From all this, the author concludes that we have been able not only to reduce the mortality of typhoid, but also to modify the severity of its symptoms. He concludes with a detailed exposition of his method of treating typhoid fever. It does not differ materially from the routine practice of our best hospitals.

3. Blood Pressure.—Wainwright gives the pulse and blood pressure charts of a number of typical accident cases which were subjected to operation. He reviews briefly the work done by Crile, and concludes with the following (condensed) summary: (1) The sensory impulses which finally cause shock at first cause a stimulation of the vasomotor centres and a rise in pressure for a certain period before exhaustion supervenes. This is the ideal stage for operative repair of the injury: i. e., primary amputation, etc. (2) Intravenous infusions are of much service in maintaining blood pressure. (3) In many cases, after the period of shock has passed, there is an excessive reaction with a considerable rise in the blood pressure. The explanation for this is still wanting. (4) While the so called cardiac shock of Howell is as yet of questionable existence some of the observations made tend to show that the condition may exist. (5) Morphine, water by the mouth, and the visits of friends tend to increase the blood pressure. Water produces its effect by reflex stimulation and not by the mechanical effect of its absorption. (6) The observations made do not show positively what effect is produced by strychnine and digitalis in cases of shock.

MEDICAL RECORD.

March 25, 1905.

1. Manuel Garcia: Teacher, Discoverer, and Man,
By JAMES E. NEWCOMB.
2. Radiotherapy and Surgery, with a Plea for Preoperative
Radiations, By WILLIAM J. MORTON.
3. Bile Tract Adhesions, By ROBERT T. MORRIS.
4. Endotracheal Injections, By J. W. GLEITSMANN.
5. The Present Status of Blood Examinations in Surgical
Diagnosis, By FREDERIC E. SONDERN.
6. Preliminary Report on the Treatment of Chronic Dysen-
tery, by Irrigation of the Colon Through the Vermi-
form Appendix or an Opening Into the Cæcum,
By WILLIAM H. ARTHUR.
7. A Warning and a Protector for X Ray Workers,
By ARTHUR HOLDING.

2. Radiotherapy.—Morton asserts that pre-operative radiation should precede every operation for cancer. It is as imperative a procedure as asepsis and the antiseptic preparation of the skin before incision. The author claims that by radiotherapy a malignant tumor becomes a strictly local affection. The paper concludes with the following summary: (1) Radiation treatment exerts a retarding effect upon the growth of some cancers. (2) It cures some cases—the ratio to operative measures is not here discussed. (3)

Preoperative radiation will increase the ratio of cures by operation. (4) Preoperative radiation transforms some inoperable cases into operable cases. (5) Preoperative radiation is recommended as a precautionary measure, probably quite as important as preoperative antiseptic preparation for surgical operation.

3. **Bile Tract Adhesions.**—Morris has arrived at the conclusion that bile tract adhesions, "gall spiders," "are a prolific source of so called gastrointestinal disorders." "How are we to make a diagnosis of gall spiders? We are to go over the tailings from the ore mill in which we previously found gastroduodenitis, diaphragmatic pleurisy, acute cholecystitis, acute indigestion, and a group of cases without very definite diagnosis in which there was a history of epigastric tenderness, rigors, febrile reaction, and general malaise lasting for a few days at a time. In going over these cases months or years after the acute symptoms have disappeared we are to note if there is undue tenderness on pressure over the bile tract—a tenderness that is pretty persistent. It may be absent on some days, but present to a greater or lesser degree most of the time. The patient will complain of a certain degree of discomfort in the bile tract region, and at times when he is most disturbed the abdominal muscles will become rigid in order to splint the disturbed peritonæum. Having found these characteristic signs of bile tract adhesions, we are to exclude other causes for the same symptoms; and that requires diagnostic acumen, and high class consultation." The following plan of treatment is advised: "Separate the webs of adhesions and prevent their recurrence by applying one or two satisfactory resources. The best resource, I think, consists in spreading a sheet of chromicized Cargile membrane over the roughened points of peritonæum, and leaving the membrane to present a mechanical obstacle to readhesion at such points. The other resource consists in sprinkling aristol over roughened points of peritonæum, and waiting for the aristol to form a protecting lymph coagulum before the abdomen is closed." There is a most promising field for the surgeon in the author's discovery, for one "cannot look over an average audience at the theatre without seeing at least fifty people who are suffering from some degree of disturbance caused by bile tract adhesions; so there is a vista of unknown horizon newly opened up for us."

5. **The Blood Count in Surgical Affections.**—Sondern from a study of 1,400 blood counts in surgical diseases reaches the following conclusions: (1) A relative percentage of polynuclear cells below 70, with an inflammatory leucocytosis of any degree, excludes the presence of gangrene or pus, at the time the blood examination is made, and usually indicates good body resistance toward infection. (2) An increased relative percentage of polynuclear cells, with little or no inflammatory leucocytosis, is still an absolute indication of the inflammatory process, and the percentage is a direct guide to the severity of the infection. In children, where the polynuclear per-

centage is normally lower than in adults, there may be pus or gangrene with the percentage as low as 73. In adults, a purulent exudate or a gangrenous process is decidedly uncommon with less than 80 per cent. of polynuclear cells, and the probability of their presence increases with the percentage. (3) An increased relative percentage of polynuclear cells with a decided inflammatory leucocytosis is the typical picture in most cases of inflammatory lesions. In general, therefore, it may be said that a marked leucocytosis indicates a good body resistance in cases in which the polynuclear count is relatively high. That is, the percentage of polynuclear cells is an index of the degree of the inflammatory lesion and the total leucocytosis should always be studied with it in mind.

INTERNATIONAL JOURNAL OF SURGERY.

March, 1905.

1. Treatment of Retrodisplacements of the Uterus, By HAYD.
2. Cantwell's Operation for Complete Epispadias, By CANTWELL.
3. Practical Gynæcology, By SELLMAN.
4. Practical Treatment of Diseases of the Eye, By COOKE.

1. **Retrodisplacements of the Uterus.**—Hayd makes a general division of retroverted uteri into (1) the complicated, and (2) the uncomplicated.

(1) The complicated are those in which there are coexisting ovarian or tubal diseases, adhesions, or anything which interferes with the normal mobility of the uterus and so contraindicates all surgical interference of an extraperitoneal nature. (2) The uncomplicated include those in which the uterus is mobile, the tubes and ovaries normal, and the prolapsus very slightly developed if it exists at all. This condition can frequently be cured by means of tampons and pessaries. Should these fail the author is accustomed to resort to the Alexander operation. The ordinary lesions of the cervix and vagina do not contraindicate this operation. It is quite possible that the patient may not be benefited by the operation and that an intraperitoneal operation will be necessary before a cure can be obtained. The Alexander operation is always safer than the intraabdominal. All of the intraabdominal operations may be objected to for some reason, and most of them are more or less faulty. When the uterus is movable and the appendages are healthy the Alexander operation is recommended. Displacements of the uterus may present no symptoms for a long time, but are almost sure to come eventually. The Alexander operation is well adapted for the changes which occur with pregnancy. The author's failures with this operation have been fewer than five per cent.

AMERICAN JOURNAL OF OBSTETRICS

March, 1905.

1. Can Our Present Method of Utilizing the Principle of Axis Traction in Obstetric Practice Be Further Developed? By JACOBSON.
2. The Prevalence of Puerperal Septicæmia in Private Practice at the Present Time Contrasted with that of a Generation Ago, By WARREN.

3. Cæsarean Section for Dystocia following Myomectomy,
By HUBBARD.
4. Indications for Cæsarean Section. Report of Two
Cases. Recovery, By MORAN.
5. Theories of Eclampsia, By DE LEE.
6. Treatment of Eclampsia, By REED.
7. The Application of the Forceps in Contracted Pelves,
By SOTHORON.
8. Fibromyomata of the Uterus, By LEWIS.
9. The Sequelæ and Treatment of Abortion, By KEYES.

1. Axis Traction in Obstetric Practice.—

Jacobson believes that the principle of axis traction control can be extended beyond the device invented by Tarnier and has designed an instrument to be attached to axis traction forceps having its support at the edge of the table to which it may be clamped. It is somewhat too complicated to explain without a diagram, but it is claimed for it that it will multiply the power exerted by the operator fifty times. The exertion of a minimum degree of force by turning a hand wheel is so multiplied, and registered upon a dial, that traction can be accomplished with mechanical precision, and any case which is suitable for forceps delivery may be delivered with the greatest ease. The conditions which the author presupposes in the use of his apparatus are: 1. Membranes ruptured; 2. cervix fully dilated; 3. bladder and rectum empty; 4. positive diagnosis of position and posture; 5. forceps clearly indicated; 6. correct application of axis traction forceps; 7. normal diameters.

By means of this apparatus the traction can be measured and as experience accumulated it would be possible to prescribe for each case the degree of traction which would be safe and proper. The possibilities of doing harm with this instrument would be small; slipping of the forceps during traction would be unattended with danger. Of course the instrument presupposes a certain amount of intelligence in the operator.

2. Puerperal Septicæmia in Private Practice.

—Warren thinks the statistics which are at hand will not admit a full answer. The nearer the obstetrician is to his graduation the better his technique and the cleaner his record. Whether puerperal infection will ever be eliminated from obstetric practice will depend upon the character of the training which the obstetricians of the future receive both at school and at the bedside. General practitioners who are now at work will not vary much from their present habits and prejudices, and the ordinary midwife cannot be expected to do clean work. The risk of infection has been practically eliminated from public midwifery.

6. Treatment of Eclampsia.—Reed recapitulates his discussion of this subject as follows: (1) Treatment should aim to control convulsions, *a*, by chloral in large doses supplemented by chloroform; *b*, by morphine in large doses supplemented by chloroform; *c*, by veratrum viride supplemented by chloroform. (2) It should seek to eliminate toxins, *a*, by way of the bowels, flushing the colon; *b*, by way of the kidneys, cupping, fluids by mouth, salines by rectum or under breasts

and skin; *c*, by way of the skin, by hot pack, or hot air. (3) The uterus should be emptied, *a*, the cervix being dilated, by forceps or version; *b*, the cervix being closed, dilatation should be effected with the fingers or with rubber bags and delivery then accomplished; *c*, the cervix being rigid and cartilaginous, Dührssen incisions, vaginal Cæsarean section, or abdominal section should be the procedure, in the order mentioned.

9. The Sequelæ and Treatment of Abortion.—

Keyes cites cases in which abortion was produced by injections of nitric acid and of lead acetate. They were usually fatal. Several writers have reported perforation of the uterus by the curette or the dilator. Such cases have also usually been fatal. Air embolism from injections into the uterus has been reported in a number of fatal cases. Endometritis is a very common sequel of abortion, uterine abscess, endosalpingitis, abscess of the tube or ovary, metropéritonitis, hæmatocele, thrombophlebitis, sapræmia, septicæmia, and pyæmia are of less frequent occurrence. Tetanus is not an infrequent sequel; hemiplegia, hemianopsia, and malignant disease are of rare occurrence. The mortality of induced abortion varies between 50 and 65 per cent. The treatment of simple threatened abortion is mainly rest in bed with suitable regulation of the diet. The treatment of inevitable abortion may be expectant or operative. In the former rest and the vaginal tampon are indicated, while the uterus must be emptied should there be fever, chills, offensive discharge, or profuse hæmorrhage. The intrauterine tampon should be used in hæmorrhage with doubtful diagnosis, inevitable abortion, incomplete abortion, and immature labor if the placenta is retained. The vaginal tampon should be used in addition to the uterine. In the operative treatment, the patient having first been subjected to antiseptic preparation, the cervix is drawn forward, the os forcibly dilated, and the uterus being pressed downward the contents are removed, if possible with the finger. If the curette is used it must be with the full knowledge of the possible damage which may be accomplished. An intrauterine douche should be used after the contents of the organ have been entirely removed.

MEDICINE

February, 1905.

1. The Diagnosis of Perforation and the Localization of
Appendicular Abscess, By CUMSTON.
2. The Nucleides of Mercury in Syphilis, By HOLLEN.

1. **Appendicular Abscess.**—Cumston adds an interesting article to the literature of this universally attractive subject. The appendix has no fixed position in the abdominal cavity, and its size, possible fixation, and relations to the cæcum are so variable that its pathological developments may occur almost anywhere in that cavity. Perforation may take place at its base, tip, or middle. When the resulting abscess is intraperitoneal it does not usually extend far from the seat of its formation. If it is extraperitoneal it may spread to an almost unlimited extent. An abscess may develop at any point within a circle, whose centre is the ileocæcal valve.

The guiding point is the position of the abscess in relation to the cæcum in the right iliac fossa. Sonnenburg classifies this relation as (1) anterior and external, (2) posterior, (3) inward, and (4) within the true pelvis. Of course all possible locations are by no means included in this classification. If a periappendicular tumor is detected by percussion, palpation, or by inspection through an incision, and there are also redness and swelling of the skin, an abscess of greater or smaller dimensions may be diagnosed with confidence. Patients with such symptoms may apparently recover and the tumor disappear, but an abscess may remain which eludes detection, but is a constant source of danger. The temperature is not always high during the formation of an abscess, and it may drop to normal. A pulse of more than 110 in the later stages of an attack indicates sepsis, if it is not due to anæmia or general debility. The urine is dark, and contains urates, indican, and albumin. The appetite is lost, there is thirst and the bowels are usually constipated. Leucocytosis is marked, and if it does not subside when the abscess is emptied, other collections of pus are probably present.

2. **The Nucleide of Mercury in Syphilis.**—Hollen reviews the various symptoms of syphilis as they usually develop and the various forms of mercury which are in general use, together with the best methods of administering them. He thinks that mercury nucleide, which contains ten per cent. of the metal, is the most favorable form in which it can be used. It is a brownish white powder, soluble in warm water, is administered in chocolate coated tablets containing one fourth of a grain, and causes no disturbance of digestion or assimilation. It combines the specific action of its base and the antiseptic action of nucleic acid. It increases the bactericidal power of the blood by the multiplication of polynuclear and mononuclear leucocytes, and is in harmony with the metabolic processes.

March, 1905.

1. Notes on a Visit to the Laboratory and Hospital of Captain E. R. Rost, I. M. S., the Discoverer of Leprolin, By RUDOLF.
2. Epilepsy, By ESHNER.
3. The Oral and Rectal Administration of Serums, By HOLLEN.

1. **The Laboratory and Hospital of Captain E. R. Rost, I. M. S.**—Rudolf refers to the helplessness of all who have tried to heal or even help sufferers from leprosy from the earliest period. The frequency of the disease in India and the Orient always makes it a subject of the highest interest and importance. The hospital in question is located at Rangoon, Burmah. Rost uses as a culture medium a distillation from beef extract, also solid agar purified from its salts. He finds that the bacillus can be cultivated only in a medium free from chlorides. Injections of the culture fluid are made at intervals of ten days. Pain, swelling, and fever to 100° F. follow the injections, the reaction lasting three days, as a rule. The quantity of leprolin to be used for each injection is ten cubic centimetres. Perspiration

in skin which has previously been dry is the first evidence that improvement is taking place. Then follow a return of sensation, increase in strength, and loosening of the contractions of the fingers and toes. Ulcers at once begin to heal, nodules and tubercles gradually become flattened and disappear. Pain in the limbs disappears early in the treatment. The mental condition and the condition of the body in general undergo marked and rapid improvement. Sixteen patients have been discharged cured from the Rangoon hospital, and many others are apparently approaching a cure.

2. **Epilepsy.**—Eshner defines epilepsy as a paroxysmal neurosis, characterized by attacks attended with derangement of consciousness or of motor coordination, with or without convulsions. An irritant of some sort underlies the paroxysm. Major, minor, focal, and psychic types are recognized. Treatment should aim at the removal of the irritating influences, and the correction of the undue irritability or instability of the sensorimotor mechanism. The mode of living should be absolutely regular in all particulars, and should be guided by the physician. Healthful and agreeable occupation is of great importance. The medical treatment of epilepsy is essentially empirical, palliative, or symptomatic. The various drugs which have been used in its treatment are well known, and include amyl nitrite, the bromides, digitalis, antipyrin, opium, trional, sulphonal, chloralhydrate, borax, etc. A change of medication from time to time is frequently beneficial. Ligation of the vertebral arteries and division of the cervical sympathetic are sometimes effective, on account of the profound impression which they produce.

3. **Administration of Serums.**—Hollen refers to the case of Porteus (*Lancet*, March 30, 1901) as the first in which diphtheritic antitoxine was given by the mouth, the patient being a nervous and hysterical child. The patient received 2,000 units and recovered. Other patients were subsequently treated with success by the same method. Macdonald has also reported cases which show that antitoxine may be given advantageously by mouth and rectum. Various other writers have had equally satisfactory results, both in human beings and animals. Hewlett, on the other hand, concluded from a series of experiments that antitoxines were not absorbed from the gastrointestinal mucous membrane. Oppenheimer says the antitoxine is destroyed in the stomach. Other evidence of a similar nature is adduced. The question is therefore undecided. If it should be found that ingestion of serum is as efficient as its hypodermic administration, the immunization of those who are exposed to diphtheria will be simplified.

1. Myasthenia Gravis, By J. TAYLOR.
2. New Methods of Studying Affections of the Heart, By J. MACKENZIE.
3. Some Practical Aspects of Conjunctival Bacteriology, By F. FERGUS.

4. A Case of Acute Endocarditis Due to the Micrococcus Gonorrhææ, By W. HUNTER.
5. After Twenty Years, By P. WARNER.
6. Industrial Anthrax (*Milroy Lectures, I*), By T. M. LEGGE.

1. **Myasthenia Gravis.**—Taylor reports two cases and discusses the symptomatology, pathology, and treatment, of the disease known as *myasthenia gravis pseudoparalytica*. It is characterized by great muscular weakness, affecting most strikingly the muscles supplied by the medulla oblongata, and which are closely related with the maintenance of the vital functions. The muscles of the limbs and trunk are also affected, and sometimes before the others. So far no definite nervous changes have been found. The first sign of weakness usually occurs in the levatores palpebrarum, giving rise to ptosis; diplopia, due to weakness of the ocular muscles, is also present. This weakness varies greatly at different times; it may sometimes be entirely absent. Nystagmus is occasionally present, likewise difficulty in mastication and weakness of the muscles of the mouth. Dribbling may occur, swallowing is difficult, and palate weakness is frequent, giving rise to a nasal voice and inability to blow out the cheeks. The laryngeal muscles are rarely affected, but a characteristic symptom is that the voice, which when the patient begins to speak is clear and strong, becomes weak and nasal, and finally fails. The respiratory muscles are affected and the patient becomes dyspnoic on the slightest exertion. In several cases death has resulted from a crisis of acute dyspnoea. The arms and legs tire easily. Walking far is impossible, and sudden falls are common. Emotional conditions and cold markedly intensify the weakness, and the patients are usually much worse at night. The reflexes are active, but may fail when the muscles are exhausted. After repeated faradaic stimulation the muscles fail to respond; with galvanism this phenomenon is not observed. Males and females suffer with almost equal frequency, and the disease occurs in childhood and old age. Occupation seems to have no influence, and in many instances the symptoms have followed some acute illness. As stated above, no definite changes have been found in the nervous structures or in the muscles. In some cases the thymus gland has been very definitely enlarged. It would seem that the terminal parts of the lower motor neuron were the parts whose function is interfered with, possibly by some toxic substance produced by an overgrown or modified thymus or the abnormal lymphoid tissue, which is occasionally found in the muscles. The diagnosis is not difficult, the cases being confused most often with nuclear palsy, diphtheritic paralysis, chronic polioencephalitis, or hysteria. The prognosis is grave, but cases may persist for many years. The danger lies in an affection of the respiratory apparatus. Strychnine given hypodermically seems to have a good influence, but so far treatment has not resulted in any modification of the diseased condition. It is to be hoped that some form of antitoxine may be discovered to antagonize the poison formed by the thymus gland or abnormal lymphoid tissue.

2. **Affections of the Heart.**—Mackenzie has endeavored to apply some of the results of recent

experimental and clinical discoveries to the explanation of certain phenomena observed in the clinical examination of the human heart. Among the points discussed are the following: (a) The functions of the heart muscle fibres. (b) Arrhythmias due to affections of these functions. (c) Nature and functions of the muscle fibres connecting auricle and ventricle. (d) Method of estimating the condition of the conductivity. (e) The inter-systolic interval. (f) Depression of conductivity without arrhythmia. (g) Influence of rest upon conductivity. (h) Arrhythmia due to depression of conductivity. (i) Bradycardia due to depression of conductivity. (k) Independent ventricular rhythm due to heartblock.

3. **Conjunctival Bacteriology.**—Fergus states that bacteriology should be in daily use in every eye clinic: 1. It is a guide in determining the safety of any operation. 2. It is an important aid in diagnoses. 3. It materially influences treatment. There are few conjunctival sacs in which microorganisms are not found; among them are staphylococci, streptococci, pneumococci, and the bacillus pyocyaneus. These may be present without exciting inflammation. The gonococcus, Weeks's bacillus, and Morax's diplobacillus probably always cause trouble. Only by bacteriological means can it be absolutely determined in the early stages to what particular organism a given case of inflammation is due; and proper treatment depends upon such differentiation. Bacteriological investigations of the cornea should always be made prior to operative procedure. Glaucoma, where any delay is out of the question, furnishes the only exception to this rule. A contagious ophthalmia, such as that caused by Weeks's bacillus or the gonococcus, must run its natural length, just as does a case of scarlet fever. No form of treatment will cut it short. On the other hand, a staphylococcus or streptococcus inflammation may be aborted by proper treatment. The former practice of fomenting eyes should be discarded; presumably nothing more aids the development of microorganisms than moist heat. Corneal ulcers are often made worse by fomentations, and they should be used only to promote supuration in the early stages of panophthalmitis, or to relieve the pain of rheumatic iritis.

6. **Industrial Anthrax.**—Legge, in the first of the Milroy lectures, deals with the 261 cases of anthrax reported in Great Britain from 1899 to 1904. Of these 88 occurred in worsted and wool workers, and 23 proved fatal: the bulk of the cases occurred in the processes of wool sorting, combing, and spinning. Fifty-three cases occurred among workers in horsehair and bristles, 17 proving fatal; the patients were principally hair curlers and brush makers. Eighty-six cases were among workers in hides and skins, at the docks, in warehouses, and in tanyards; 21 died. The cases among wool workers are confined almost entirely to places where dangerous classes of wool are used—those from Persia, Turkey, and Switzerland. No cases have been traced to the use of Australian wool. The infected horsehair may come from China or Russia: the hides and skins from Italy or South America. The characteristic of anthrax to infect certain districts has been known for years.

4. On the Diagnosis and Treatment of Hypertrophy of the Pylorus in Infants,

By G. F. STILL.

5. Acute Ascending Paralysis in Cases of Chronic Cystitis,

By T. J. WALKER.

6. Further Notes on the After-History of Cases of Pyloroplasty,

By G. G. TURNER.

1. **Peritonitis.**—Dudgeon and Sargent, in their third lecture, state that their observations have led them to the conclusion that the staphylococcus albus exercises some sort of protective action in peritonitis and that by determining the advent of phagocytes. It, therefore, in nature, takes the place of those chemical substances which are capable of producing an artificial immunity. It is the first to arrive upon the scene, and provokes the appearance of a clear fluid exudate, which soon becomes turbid from the presence of innumerable phagocytes. Later the more virulent organism, in the majority of cases the colon bacillus, appears, and it is upon the start, so to speak, which the staphylococcus has had, and the ability to answer the call, that the prognosis to a large extent depends. Generally speaking, if the staphylococcus albus is found alone, the outlook is good. If the colon bacillus is also present the outlook is graver, and if the colon bacillus is found alone the patient will probably die. The staphylococcus albus is the last to disappear when the individual has overcome the infection, and may persist for a long while. This may explain why later attacks of appendicitis are seldom or never of an acute fulminating type. The staphylococcus albus also exerts a protective action by assisting the formation of adhesions. It seems probable that as soon as the intestine becomes distended and congested, the staphylococcus albus makes its way out at any and every point, to be followed at a later period, if the obstruction is unrelieved, by other organisms, notably the colon bacillus. A prognosis can be made from examination of films taken from a remote region of the peritonæum. If phagocytic cells are abundant and if cocci other than streptococci are present the prognosis should be favorable. But if cells are scanty and disintegrated and bacilli are alone or predominate, or if streptococci are present, then the case may be regarded as hopeless.

2. **Conjunctivitis.**—Mayou, in the second of the Hunterian lectures, states that in all the acute forms of conjunctivitis the discharge is principally made up of polymorphonuclear neutrophils with an occasional polymorphonuclear eosinophile: the latter cell may be greatly increased in numbers in pemphigus. In the chronic forms of conjunctivitis plasma cells are found in large numbers. Mast cells are found in the discharge principally in diseases of the subepithelial tissue. The cells undergo degeneration by vacuolization, due to the digestion of organisms; hypochromatosis, gradual fading due

to absorption of fluid; and pyknosis, shrinking of the protoplasm due to the loss of fluid. The writer then goes on to describe the characteristic histological changes which take place in gonorrhoeal conjunctivitis (adult form and ophthalmia neonatorum), Koch-Weeks conjunctivitis, and diplobacillary conjunctivitis.

3. **Toxic Insanity.**—Savage, in his second Lettsomian lecture, discusses the various mental and nervous disorders which depend chiefly upon toxic agents directly, or upon secondary toxins produced by the primary infections. He divides the toxic agents into those from without, as alcohol, morphine, cocaine, etc.; those which form within the body as a result of some infection, directly as from influenza, or indirectly as from syphilis; those which are the result of disordered metabolism, as in Bright's disease, myxœdema, or diabetes; those producing acute delirious mania (the acute bacillary delirium of some writers); and those due to organisms from without getting directly into the blood stream. The disorder is most commonly generalized; next comes confusion of function, followed by sensory and motor troubles; then there is loss of higher control, of self respect, and the craving for the cause, and the yielding to temptation. Defective memory is a conspicuous symptom, and the end is generally dementia.

4. **Infantile Pyloric Hypertrophy.**—Still states that no combination of symptoms is sufficient for the diagnosis of congenital hypertrophy of the pylorus in the absence of well marked visible peristalsis of the stomach associated with palpable thickening of the pylorus. On these two signs certainty depends. The majority of the cases occur in boys: the onset of the disease is almost invariably before the age of three months, and death usually results within a month. Vomiting is chronic and persistent, is very forcible, occurs in the most carefully fed children, and usually consists of more than one feeding, as shown by its large amount. Constipation may or may not be present: wasting may be the symptom which has attracted most attention. Treatment by stomach washing is the method which, apart from operation, promises to be of most value and should be given a trial in every case, as some typical cases have seemed to recover completely under its use. The stomach is washed out with a solution of sodium bicarbonate twice daily for some weeks just before feeding.

5. **Paralysis in Cystitis.**—Walker has met with three cases of long standing chronic cystitis which terminated fatally by acute ascending paralysis of a most malignant type. Assuming it to be true that Landry's paralysis is an intoxication of the nervous centres due to infection by specific microbes, the pathology of these cases is explained as follows: The specific microbes were to be found in the urinary organs, probably in the bladder; at a certain stage of the disease they were conveyed along the same course, almost certainly the nerves, by which inflammation spreads from the urinary organs in paraplegia urinaria to the cord, in which medium they developed rapidly, producing a virulent intoxication; and the tissues were weakened by the long standing cystitis.

Letters to the Editor.

LOCOMOTOR ATAXIA VERSUS BURSTITIS.

70 LENOX AVENUE,

NEW YORK, March 22, 1905.

To the Editor,

Sir: I have carefully noted in your issue of March 18th the somewhat captious and to me surprising criticisms of a case of locomotor ataxia reported in my paper on this subject, published in the *Journal* of February 18, 1905, as made by Dr. Louis Friedman. As I made no reference to the doctor in my report of the case, and would under no circumstance be guilty of any such discourtesy, I am at a loss to understand why Dr. Friedman should question the diagnosis of a case on the bare assumption that it was in a former patient of his own. In referring to the history of the case my remark was that "one young physician was quite insistent as to the necessity of removing a bursa." I am left to infer that the shoe fits the author of the criticism.

"Surely," remarks Dr. Friedman, "the doctor could not by the use of the ultraviolet ray, combined with peripheral treatment and local galvanization, applied to the lumbar region, cure and restore to function a Charcot's joint, as he reports." This single remark is conclusive evidence that Dr. Friedman either carelessly read or failed to understand my paper. To which of these charges is he willing to plead guilty?

I have received hundreds of letters from physicians in all parts of the country asking for further and more detailed information about the treatment, but not one of these many correspondents has failed to recognize the case as one of locomotor ataxia and not of mere bursitis, as assumed by my critic. On the basis of my replies to these inquiries a number of practitioners have adopted my method in this intractable and painful disease, and have reported very encouraging success.

Dr. Friedman practically admits that he is not familiar with the use of the ultraviolet ray in locomotor ataxia. Ruskin says that for a man to express an opinion of a subject which he does not understand is an impertinence. Things that are not understood are always mysterious, but it does not follow that they are valueless or untrue, because some one does not understand them. Thirty years ago ovariectomy was something of a surgical experiment and therefore, to those surgeons who had not mastered its technique, a mystery. To-day even Dr. Friedman will concede that it is a simple operation. Evidently electricity, in its many modalities, is a profound mystery to those who have not thoroughly investigated it, a class to which Dr. Friedman must belong.

Recurring briefly to the subject of locomotor ataxia, it is impossible to be too careful and guarded in examining a case and reaching a diagnosis. In fact, the nicest discrimination is required in analyzing the symptoms in each case, since some of them are always very obscure. Dr. Friedman says he failed to find any symptoms of

the same one I reported. I will not for a moment question his word or his diagnostic skill, but this, I respectfully submit, is no reason for denying that such symptoms were present in the case I reported.

In my description of the case I said there was no pain on pressure, but that the unmistakably pathognomonic "lightninglike, boring" pains, radiating from the hip to the heel, were present and were so severe that the patient could walk only by lifting the heel two inches from the floor or ground. Any tyro in pathology will not make the mistake of calling these the pains of bursitis. In my case these pains were present in both limbs. Will Dr. Friedman insist that there was therefore a double bursitis? The doctor admits that I "cured" the patient of these terrible pains—without removing a bursa. Readers of the *Journal* who have followed the case will have no hesitancy in deciding whether or not my diagnosis was correct.

I will add that not only the locomotor ataxia was radically cured, but also a condition of supposed flat foot, requiring the use of metal arch supporters, was entirely relieved, and the patient still remains able to stand on his feet, attending to his usual occupation, for from seven to nine hours per diem, and that he walks with a normal and perfect gait.

J. MONROE LIEBERMANN.

Proceedings of Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of February 8, 1905.

The President, Dr. JAMES M. ANDERS, in the Chair.

A "SYMPOSIUM" ON GASTRIC ULCER.

Ætiology and Pathology.—Dr. JOSEPH MCFARLAND, in the first paper read, concluded that two factors, one incidental and one essential, were engaged in the ætiology of gastric ulcer. The incidental factor was the gastric juice, containing the proteolytic element without which the formation of gastric ulcer was impossible. The essential factor was a loss of the natural immunity of a circumscribed portion of the gastric mucous membrane in consequence of malnutrition, resulting from thrombosis, embolism, injury, or other obstructions of the minute nutrient vessels in the gastric wall or infectious or toxic agents circulating in these vessels. The relation of anæmia to gastric ulcer was quite as probably secondary as primary. That is, instead of the anæmia being the cause of the disease, it was quite as likely to be its effect.

Incidence in Philadelphia.—Dr. ALBERT PHILIP FRANCINE analyzed the post mortem records of the Philadelphia Hospital for ten years from January 1, 1893, to December 31, 1903, inclusive, and based the following conclusions upon the result of his studies: Total number of autopsies in ten years, 2,830. Those in association with chronic nephritis, sixteen gastric

and one duodenal; with tuberculosis, miliary or of the lungs, eleven gastric and one duodenal; with both tuberculosis and nephritis, three gastric; with chronic bronchitis, one gastric; with pneumonia, one gastric; with atelectasis of the lung, one both gastric and duodenal; with carcinoma of the stomach or some other part, four gastric; with fatty heart, one both gastric and duodenal; with enterocolitis in infants, two gastric. In twenty out of forty-two cases, or 0.47 per cent., the ulcers were multiple. Mayo had said that in twenty per cent. of the cases more than one ulcer was present. The sexes in Dr. Francine's series were equally divided. The average age for males was forty-three years; for females, the same. Welch had found forty per cent. in males and sixty per cent. in females. The largest number of cases in his series occurred in males between thirty and forty years old, and in females between twenty and thirty years. In Dr. Francine's series the greatest number of cases occurred in males (five) between fifty and sixty years and in females (five) between forty and fifty years. Three of the cases were in infants, ten, twenty and thirty-six months old. Osler had mentioned a case reported by Goodhart in an infant thirty hours old. The largest ulcer in Dr. Francine's series was 9 to 10 cm. by 8 to 10 cm. He quoted Dr. Joseph Walsh, late pathologist to the Henry Phipps Institute, as saying that during his service, in 1903, there were fifty-two autopsies on those dead of tuberculosis, and that in one case he found numerous small superficial ulcers in the stomach. In the service of the following year, of fifty-five autopsies, there was no instance of gastric or duodenal ulcer.

Symptomatology and Diagnosis.—Dr. CAMPBELL P. HOWARD, of Baltimore (by invitation), read a paper upon this feature of the subject. The mode of onset in the majority of cases, he said, was gradual and insidious. In the smaller group hæmatemesis and perforation were sudden. In acute gastric ulcer blood was as a rule vomited. In the chronic form pain, vomiting, and hæmatemesis were cardinal symptoms. In every case of gastric ulcer there was some hæmorrhage, though it might not appear for months or years after the onset. The physical examination was negative in many complicated cases, except that tenderness was present. The most frequent secondary complications were hypertrophy of the pylorus, adhesions, and inverted viscera. Dilatation of the stomach in an ulcer case signified pyloric obstruction. Few diseases presented more difficulties in diagnosis.

Medical Treatment.—Dr. F. P. HENRY presented this part of the subject. That the tendency of gastric ulcer was toward recovery was proved by the frequency of characteristic cicatrices in the stomach post mortem. The object of treatment should therefore be to assist Nature, and the most important indication was rest, both general and local. The latter was best secured by rectal feeding plus bland and nutritious articles of diet. Opium and its preparations per os were conducive to rest by allaying pain and peristalsis and blunting the appetite. Hyperacidity should be counteracted by lime water and bismuth rather than by sodium bicarbonate, which, on account of the evolution of gas attendant on its administration, might distend the stomach

to a dangerous extent. Milk, raw, boiled, or peptonized, he considered the best article of diet in the early stages. Buttermilk was sometimes an excellent succedaneum. The formation of tough coagula might be prevented by mingling the milk with a little well boiled flour or arrowroot. Medicinal treatment he regarded of secondary value to dietetic, but doubtless serviceable. He recommended bismuth subnitrate in large doses suspended in barley water or mucilage. Nitrate of silver he believed to be useless, and calomel injurious and interfering with the healing processes. Carlsbad water and Carlsbad salts he had found useful as antacids and laxatives. When chlorosis was present, iron albumin, prepared extemporaneously by mingling a solution of sesquichloride of iron with "egg water," was recommended. Leube's method of treating gastric ulcer by continuous poulticing was discussed. Leube's statistics, founded on 556 cases, gave a mortality of 2.2 per cent., instead of 13, which was the percentage under ordinary methods. Dr. Henry's method was a modification of Leube's in that he used opiates, which Leube condemned, and nourished by rectal enemata during the first week of treatment.

Surgical Treatment.—Dr. WILLIAM L. RODMAN considered the surgical treatment of gastric ulcer. This, he stated, resolved itself into treatment of the ulcer itself and that of the several complications. He believed that perforation was far more common than was thought. The treatment of hæmorrhage was generally medicinal, but if it was a recurring feature, the treatment should be surgical. The treatment of stricture or hour glass stomach was a question of physics and not of chemistry, and should be generally by operation. Uncomplicated gastric ulcer in the vast majority of instances could be treated by medical means. He referred to the various surgical methods for the treatment of gastric ulcer and concluded that one should operate only after medical means had been fairly tried for at least four weeks without results. Then the abdomen should be opened, but without any positive convictions of what should be done until the stomach was examined from the pylorus to the cardia, after which the procedure best adapted to the conditions present should be carried out.

Dr. ALFRED STENGEL agreed with Dr. Howard that it was possible to distinguish between the acute and chronic forms of ulcer, but believed that this was a clinical rather than a pathological distinction. Chronic forms of ulcer impressed him as being simply of the indolent type with the same general pathological basis and nature as the acute, but with different local conditions which caused their different course. Statistics would be much clearer if all cases were based upon a pathological study after careful discrimination between the different types of ulcers and erosions, which ought not to be called ulcers.

In treatment, he agreed with Dr. Henry that gastric ulcer was a medical disease, unless resistance showed that medical treatment would not avail. After a consideration of the principal symptoms of gastric ulcer, hæmatemesis, pain, and dyspeptic disturbance, there was a considerable proportion of cases in which the diagnosis must be in doubt. He thought the frequent association of gastric ulcer

with nephritis and tuberculosis shown by Dr. Francine in the statistics of Blockley might be accounted for by the character of the patients in that hospital.

Dr. JOHN H. GIBBON regarded the subject as of particular interest on account of the complications. He believed that many persons with gastric ulcer that recovered after an operation did so because of the after treatment, and he agreed with Dr. Stengel that the patient should be fed by the bowel for three weeks. He referred to the fact that often in the presence of gastric symptoms and a palpable tumor in the abdomen there was the belief that malignancy was present, and a wrong prognosis was therefore given. In all such cases where there was the slightest question of doubt he advises exploratory operation.

Dr. LAMBERT OTT found that the administration of five grains of nitrate of silver in six ounces of water, a tablespoonful in a wineglass of water half an hour before meals, gave good results. He did not approve of boiled milk, but had accomplished the best results in using as a food milk as a basis, with broth.

Dr. JOSEPH SAILER said that the rather small percentage of gastric ulcer in this country suggested the possibility of the condition being overlooked by pathologists. He thought the most important element in the treatment was absolute rest. Reports of different men showed practically the same results whether feeding was by the mouth or by the rectum. Personally he preferred the latter method. After beginning alimentation by the mouth olive oil and some of the bland nutriment might be given without harm to the mucous membrane of the stomach. The entire disappearance of symptoms for two or three weeks, with no blood in the stools and the patient on a liberal diet, might be accepted as evidence of recovery.

New Inventions.

THE IMPROVED OFFICE TABLE FOR THE GENERAL PRACTITIONER.

There could be no more convincing proof of the increased demands upon the general practitioner than the improved equipment devised for his assistance.

In their table, style 36, the W. D. Allison Company have given the profession an appliance which offers not only the conveniences of automatic connection of back and leg rest, but the entire range of independent adjustment, as well as a combination which for many years seemed unattainable. Instead of sacrificing such positions as the Trendelenburg and genitourinary to the automatic leg rest, the positions are secured more easily than ever before with modifications of the highest value.

For example, in the genitourinary position, which is illustrated herewith, the operator may, if desired, swing the leg rests apart and thus separate the limbs of the patient, all the while keeping the feet elevated to insure relaxed abdominal muscles.

In such positions as the "Sims" and "drainage," the leg rests may be detached or swung

Improved office table, style 36.

outward for use as side tables for instruments, cotton, or bandages. The evident object is to save the time and strength of operator and patient, thus insuring the highest degree of efficiency in results.

Book Notices.

The Modern Mastoid Operation. By FREDERICK WHITING, A. M., M. D., Professor of Otology, Cornell University Medical College, etc. Illustrated by Twenty-five Half Tone and Twenty-three Key Plates made from Original Drawings. Philadelphia: P. Blakiston's Son & Co., 1905. (Price, \$6.)

This "little book," as the author modestly styles a sumptuous and beautifully illustrated octavo volume of some three hundred and fifty pages, is a complete guide to one of the most important procedures of modern surgery, by an otologist of wide experience and progressive tendency. An introductory chapter deals with the history of operations for the relief of acute mastoiditis, Wilde's incision, trepanation, drilling, and the Schwartze operation. The body of the work is devoted to the "complete" modern operation.

Whiting performs a flap operation, supplementing the usual incision by a horizontal cut backward at its middle. The complete removal of the mastoid tip, of the zygomatic cells, and of those overlying the sigmoid groove is recommended as a routine procedure. To each of the various operative steps a chapter is devoted, the essentials appearing in large type at the beginning of each section. The gist of the technical directions may thus be obtained rapidly, but the surgeon as well as the student will be amply repaid by a more thorough study of the work, which is full of practical instruction. The short epitome on faults of technique incidental to each step may be cited in point. The chapters on postoperative treatment and on the instrumentarium are unique in their completeness, attention to detail, and refreshing directness. Throughout the book there is an absence of generalization, and there is clear teaching on every point, from the landmarks for the sinus to the choice of a scalpel. Practical work on the operative table and at the bedside, indispensable as it is, becomes more intelligent and accurate when supplemented by such instruction.

The illustrations represent various types of mastoids and the successive stages of the operation.

The latter are reproductions of wash drawings admirably made from life.

The key plates are line drawings printed on thin paper to serve as diagrams, and to accentuate the important details of the complete picture shown opposite. They add greatly to the didactic value of the work.

Spezielle Diagnose der inneren Krankheiten. Ein Handbuch für Aerzte und Studierende nach Vorlesungen bearbeitet. Von Dr. WILHELM v. LEUBE, Professor der medizinischen Klinik und Oberarzt am Juliusospital in Würzburg. I. Band. Siebente neu bearbeitete Auflage. Mit 28 Abbildungen. Leipzig: F. C. W. Vogel, 1904. (Pp. xii-562. (Price, 13 M.)

The deserved esteem in which this important work is held in Germany is indicated by the need of this seventh edition. The sixth German edition has been translated and recently published in this country. In its present form the author states that the work is largely new, not merely revised, but rewritten to keep pace with the rapid advances which are making in internal medicine. In an introductory chapter the analytical, inductive methods of diagnosis are considered in an able manner which impresses one as the mature experience of a great teacher. The value of the training afforded by necropsies is properly emphasized. Von Leube says: "I freely admit that whatever diagnostic skill I may possess is in great measure due to my experience in pathological anatomy." In a work so generally excellent it is difficult in a brief notice to select special features for comment, and yet the chapters on the stomach and intestines, as would be expected, are certainly noteworthy. The author is here in his own special field and writes as an authority on these organs, no small part of the original work, which has so advanced and revolutionized our knowledge of diseased conditions of the digestive tract in recent times, having been contributed by him and his pupils. A commendable feature of the work is the judicious restraint shown in the use of illustration. Overillustration, a common vice in medical textbooks of to-day, usually serves little purpose other than to cover meagreness in the text.

Lectures on Diseases of Children. By ROBERT HUTCHISON, M. D., F. R. C. P., Assistant Physician to the London Hospital and to the Hospital for Sick Children, Etc. London: Edward Arnold, 1904. Pp. xii-338. (Price, 8s. 6d.)

This little book is unique in pediatric literature. It consists of a series of lectures delivered at the London Hospital, and is in no way an exhaustive treatise on the diseases of children. The author considers those common diseases as well as some of the conditions to which the term disease can scarcely be applied, which receive very little attention in the ordinary textbook and in the average college lecture. It is purely clinical in nature, though some attention is devoted to therapeutics. It deals in a simple manner with some of the subjects which receive very scant attention from most teachers and writers, and will prove especially helpful to the young practitioner. A most valuable chapter to the practitioner of any age is that on symptoms of disease in children and their diagnostic significance.

Transactions of the American Ophthalmological Society. Fortieth Annual Meeting, Atlantic City, N. J., 1904. Vol. X, Part II. Hartford: Published by the Society, 1904.

Ophthalmologists are to be congratulated that a society exists which can annually add such valuable scientific contributions to the knowledge of the eye. It would take too much space to review each article as it deserves, but the one presented by the president, Dr. C. S. Bull, on operations on the eyeball in the presence of an infected conjunctiva, should be mentioned because the practical preparation of an eye to undergo operation is thoroughly discussed. Even though every operating ophthalmic surgeon may not agree with all Dr. Bull's conclusions, the statements made and the ideas advanced deserve the careful study of every one who is likely to be called upon to operate on an eye.

Miscellany.

The Use of Proprietary Preparations.—The *Massachusetts Medical Journal* says editorially in a recent issue: In looking over some addresses delivered at the annual meetings of different medical societies, we have been struck, if not amused, by the stress laid in each one of them on the impropriety of physicians prescribing proprietary preparations. We may be very dense, but we confess that we cannot see any good reason why the man who discovers a new remedy, or even makes a new and useful combination of old remedies, should not be amply compensated for his labor; or why reputable physicians should refuse to "patronize" such remedies. The doctor who prescribes, the retail druggist who fills the prescription, the wholesale druggist, the manufacturer, each of these expects to be paid; why, then, shall we expect the man who has spent his time and money in discovering and investigating the remedy to go unrewarded? Such work often requires the highest degree of chemical and pharmaceutical skill and a large outlay of capital and labor, and to expect men to engage in such enterprises out of pure philanthropy is sentimental nonsense of the purest ray serene. It would be just as rational to demand that every inventor should make a free gift of his invention to the world. Shall the man who invented metal tips for shoe strings or a shade roller reap a fortune, and shall not the man who conferred upon humanity the boon of sulphonal, or aristol, say, do the same?

On the contrary, properly compensating the discoverer of new remedies, allowing him to take out a patent on his preparation, attracts capital and skill to this field of labor to the immense benefit of mankind. If a skillful chemist knows that he can make a fortune by devoting his attention to the chemistry of the arts and manufactures, why should he waste his time in pharmacology if this is to be a mere "thankie job"?

There are those of the "righteous overmuch" type, who affect to dispense with all proprietary medicines, and who boast that they can improvise mixtures which are "just as good." May heaven

help those unfortunate beings who have to stomach their improvisations!

This is a matter which should be settled upon plain, everyday, business principles. The world can well afford to pay inventors of new remedies well; it is not a huge eleemosynary institution, as some would have us believe; the cases where paupers languish and die for lack of highly priced drugs are very, very few.

It is, then, a matter of simple justice that the inventor of remedies should be paid as well as the inventor of air brakes. The conclusion is that no progressive physicians can afford to dispense with many of the so called proprietary remedies or preparations.

Official News.

Public Health and Marine Hospital Service Health Reports:

The following cases of smallpox, yellow fever, cholera, and plague, have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended March 24, 1905:

Smallpox—United States.

Public Health and Marine Hospital Service:

List of Changes of Station and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending March 22, 1905:

FRICK, JOHN, Acting Assistant Surgeon. Relieved from duty at Laredo, Texas, and directed to proceed to Tampico, Mexico, for duty in office of American Consul.

FRICKS, L. D., Passed Assistant Surgeon. Relieved from duty at the Immigration Depot, New York, and directed to proceed to Castries, St. Lucia, W. I., for duty in the office of the American Consular Agent. March 17, 1905.

GLENYAN, A. H., Assistant Surgeon-General. Granted an extension of leave of absence for three days from March 21st.

GOLDSBOROUGH, B. W., Acting Assistant Surgeon. Granted leave of absence for three days from March 23rd.

KERR, J. W., Passed Assistant Surgeon. Granted leave of absence for five days from March 14, 1905, under paragraph 191 of the regulations.

KURTZ, W. E., Acting Assistant Surgeon. Granted leave of absence for seven days from March 18, 1905, under paragraph 210 of the regulations.

McLARY, A. A., Acting Assistant Surgeon. Granted leave of absence for thirty days from April 1st.

McLAUGHLIN, A. J., Assistant Surgeon. Granted leave of absence for six days from March 20th.

MATHEWSON, H. S., Passed Assistant Surgeon. Bureau letter of March 11th, granting Passed Assistant Surgeon Mathewson leave of absence for five days from March 13th, amended to read six days from March 13, 1905.

SAWTELLE, H. W., Surgeon. Granted leave of absence for two days from March 17th.

WILSON, R. L., Passed Assistant Surgeon. To proceed to Vera Cruz, Mexico, for duty in the office of the American Consul.

Board Convened.

Board convened to meet at Washington, D. C., March 18, 1905, for the physical examination of an officer of the Revenue Cutter Service. Detail for the board—Assistant Surgeon General W. J. PETTUS, chairman. Assistant Surgeon General H. D. GEDDINGS. Assistant Surgeon A. J. McLAUGHLIN, recorder.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending March 25, 1905:

BARTLETT, C. J., First Lieutenant and Assistant Surgeon. Leave of absence extended twenty days.

HALL, JOHN D., Colonel and Assistant Surgeon-General. Assigned to duty as chief surgeon of the Department of California.

McCULLOCH, C. C., Jr., Major and Surgeon. Granted thirty days' leave of absence.

MEARNS, E. A., Major and Surgeon. Granted three months' sick leave of absence.

RAFFERTY, OGDEN, Major and Surgeon. Ordered to proceed to the artillery posts in District of Potomac and Baltimore, with a view to determine the requirements of the medical department at each station participating in Army and Navy exercises from June 11 to 17, 1905.

TURNBULL, WILFRID, First Lieutenant and Assistant Surgeon. Honorably discharged from the service of the United States, under the provisions of the act of Congress, approved October 1, 1890, as amended by the act approved July 27, 1892, to take effect March 17, 1905.

WINN, ROBERT N., First Lieutenant and Assistant Surgeon. Granted three months' leave of absence, to take effect about June 1, 1905.

The following assistant surgeons have been ordered, on completion of course of instruction at the Army Medical School, Washington, D. C., to Manila, P. I., for duty in the Division of the Philippines: HOWARD H. BAILY, HENRY L. BROWN, ROBERT M. CULLER, WILLIAM R. DAVIS, PAUL L. FREEMAN, H. G. HUMPHREYS, LEARTUS J. OWEN, FRANK W. WEED, WILLIAM A. WICKLINE, and STANLEY G. ZINKE.

Navy Intelligence:

Official List of Changes in the Medical Corps of the United States Navy for the week ending March 25, 1905:

BLACKBURN, T. C., Acting Assistant Surgeon. Detached from the *Culca* and ordered to recruiting party No. 2, at Dallas, Texas.

BLACKWELL, E. M., Passed Assistant Surgeon. Detached from the *Cassine* and ordered to the Naval Station, San Juan, P. R.

BISHOP, L. W., Passed Assistant Surgeon. Commissioned a passed assistant surgeon in the United States Navy, with rank of lieutenant, from September 28, 1904.

BOGERT, E. S., Surgeon. Detached from the Naval Academy, March 25, 1905, and ordered to the *West Virginia*.

BUTLER, C. S., Passed Assistant Surgeon. Detached from the Naval Station, San Juan, P. R., and ordered to the *Castine*.

CRANDALL, R. P., Surgeon. Ordered to the *Hancock*.

DABNEY, V., Acting Assistant Surgeon. Detached from recruiting party No. 2 and ordered to the *Culcoa*.

DICKINSON, D., Medical Director. Detached from the Naval Hospital, Chelsea, Mass., and ordered to the Navy Yard, Portsmouth, N. H., and to additional duty in command of the Naval Hospital, at that place, on April 6, 1905.

DICKSON, S. K., Medical Director. Detached from the *Kearsarge* and ordered to the *Maine*.

DRAKE, N. H., Medical Director. Detached from the *Hancock* and ordered to the Navy Yard, Norfolk, Va.

FARWELL, W. G., Medical Director. Detached from the Naval Hospital, Portsmouth, N. H., and ordered home, April 4, 1905.

GROW, E. J., Surgeon. Commissioned a surgeon, with the rank of lieutenant commander, from March 3, 1903.

GRUNWELL, A. G., Surgeon. Commissioned a surgeon, with the rank of lieutenant commander, from March 3, 1903.

HENEBERGER, L. G., Medical Inspector. Ordered to duty in command of the Naval Hospital, Newport, R. I.

JANNEY, W. H., Acting Assistant Surgeon. Detached from the *Cesar*, and resignation accepted, to take effect March 22, 1905.

JOHNSON, M. K., Surgeon. Detached from the *Tacoma* and ordered to the *Maine*.

KITE, I. W., Surgeon. Detached from the *Maine* and ordered to the *Kearsarge*.

LANGHORNE, C. D., Surgeon. Commissioned a surgeon, with the rank of lieutenant commander, from March 3, 1903.

LUMSDEN, C. P., Surgeon. Detached from the Navy Yard, Norfolk, Va., and ordered to the *Minneapolis*.

SELLERS, F. E., Acting Assistant Surgeon. Detached from the Naval Station, Culebra, and ordered home to await orders.

SHIFFERT, H. C., Passed Assistant Surgeon. Commissioned a passed assistant surgeon, with the rank of lieutenant, from December 26, 1903.

SHOOK, F. M., Assistant Surgeon. Appointed an assistant surgeon, with the rank of lieutenant, junior grade, from March 15, 1905.

SNYDER, J. J., Passed Assistant Surgeon. Detached from the *Kearsarge* and ordered to the *Tacoma*.

STUART, ALLAN, Passed Assistant Surgeon. Commissioned a passed assistant surgeon, with the rank of lieutenant, from June 7, 1904.

TOLFREE, H. M., Assistant Surgeon. Detached from the *Hancock*, April 13, 1905, and ordered to Washington, D. C., for examination for promotion, and then to await orders.

WELLS, H., Medical Director. Detached from the Naval Hospital, Newport, R. I., and ordered to duty in command of the Naval Hospital, Chelsea, Mass.

WINN, C. K., Acting Assistant Surgeon. Detached from the Naval Hospital, Norfolk, Va., and ordered to the *Cesar*.

The following assistant surgeons were detached from duty at the Naval Museum of Hygiene and Medical School, Washington, D. C., and ordered to duty as follows:

ANGWIN, W. A., Naval Academy, Annapolis.

BELKNAP, J. L., Naval Hospital, Narragansett Bay, R. I.

CHAPMAN, R. B., Naval Hospital, Mare Island, Cal.

COLE, N. W., JR., Naval Hospital, Norfolk, Va.

FARWELL, W. G., Naval Hospital, New York, N. Y.

GRAYSON, C. T., Marine Barracks, Washington, D. C.

HEINER, R. G., Navy Yard, Washington, D. C.

HULL, H. F., United States Revenue Steamer *Franklin*.

MAY, H. A., United States Revenue Steamer *Franklin*.

MCDONNELL, W. N., Naval Station, Porto Rico, and additional duty on the *Alliance*.

MCLEAN, N. T., Naval Hospital, Chelsea, Mass.

MINK, O. J., Naval Hospital, New York, N. Y.

NELSON, H. T., Naval Hospital, Washington, D. C.

OWENS, W. D., Naval Hospital, Mare Island, California.

PORTER, F. E., Naval Hospital, Norfolk, Va.

STOOPS, R. E., *Pensacola*, and additional duty at the Naval Training Station, San Francisco, Cal.

STRITE, C. E., Naval Hospital, Norfolk, Va.

VICKERY, E. A., Navy Yard, Portsmouth, N. H., and additional duty on the *Southerly*.

WHEELER, L. H., Naval Hospital, Narragansett Bay, R. I.

WICKES, G. L., United States Revenue Steamer *Lancaster*.

ZALESKY, W. J., Naval Academy, Annapolis.

Births, Marriages, and Deaths.

Married.

DUNHAM—HICKENLOOPER.—In Cincinnati, Ohio, on Wednesday, March 15th, Dr. Harry Kennon Dunham and Miss Amelia Hickenlooper.

GILMAN—MARTIN.—In Brooklyn, N. Y., on Thursday, March 9th, Dr. Ray Edward Gilman and Miss Lillie Osborn Martin.

SOUTH—TURNBULL.—In Philadelphia, on Saturday, March 18th, Lieutenant Hamilton Disston South, United States Marine Corps, and Miss Elizabeth Turnbull, daughter of Dr. and Mrs. Charles Smith Turnbull.

THOMAS—BENEDICT.—In Brooklyn, N. Y., on Wednesday, March 8th, Dr. William E. Thomas and Miss Esther L. Benedict.

Died.

BEEBE.—In Denver, Colorado, on Monday, March 13th, Dr. Carolyn Dewey Beebe, in the fortieth year of her age.

BOEBER.—In Guadalajara, Mexico, on Sunday, March 12th, Dr. E. J. Boeber, in the thirty-fifth year of his age.

BRUNDAGE.—In Brooklyn, N. Y., on Sunday, March 19th, Dr. Amos Harrison Brundage, in the seventy-seventh year of his age.

DULIN.—In Denver, Colorado, on Tuesday, March 14th, Dr. Frank Dulin, in the forty-fifth year of his age.

FENNER.—In Fredonia, N. Y., on Tuesday, March 14th, Dr. Milton M. Fenner, in the sixty-eighth year of his age.

GALE.—At sea, on Friday, March 17th, Dr. Alexander F. H. Gale, of New York, in the thirty-fifth year of his age.

GREENFIELD.—In Trinidad, Colorado, on Monday, March 13th, Dr. R. A. Greenfield, in the sixty-second year of his age.

HOPPIN.—In Philadelphia, on Tuesday, March 21st, Dr. Samuel B. Hoppin, in the eighty-seventh year of his age.

LOMBARD.—In Boston, Massachusetts, on Tuesday, March 21st, Dr. John P. Lombard, in the forty-fifth year of his age.

MACALLISTER.—In San Francisco, California, on Wednesday, March 8th, Dr. Eleanor MacAllister, in the thirty-ninth year of her age.

MCPHEETERS.—In St. Louis, Missouri, on Wednesday, March 15th, Dr. William M. McPheeters, in the ninetieth year of his age.

MEYER.—In Milwaukee, Wisconsin, on Wednesday, March 15th, Dr. William Meyer, in the fiftieth year of his age.

MURDOCH.—In Baltimore, Maryland, on Sunday, March 19th, Dr. Russell Murdoch, in the sixty-seventh year of his age.

SPRING.—In Minneapolis, Minnesota, on Wednesday, March 22nd, Dr. W. P. Spring.

TREADWELL.—In Elgin, Illinois, on Friday, March 17th, Dr. William E. Treadwell, in the fifty-fourth year of his age.

WRIGHT.—In Deland, Florida, on Tuesday, March 14th, Dr. C. Edwin Wright, of Philadelphia, in the fifty-ninth year of his age.

Original Communications.

THE OPERATIVE TREATMENT OF CHRONIC SUPPURATIVE OTITIS.*

By ARTHUR B. DUEL, M. D.,

NEW YORK.

ATTENDING AURAL SURGEON TO THE MANHATTAN EYE, EAR,
AND THROAT HOSPITAL; CONSULTING AURAL SURGEON TO
THE NEW YORK BOARD OF HEALTH; OTOLOGIST TO THE
BABIES' HOSPITAL; FELLOW OF THE AMERICAN
OTOLOGICAL SOCIETY; NEW YORK OTOLOGICAL
SOCIETY; NEW YORK ACADEMY OF
MEDICINE, ETC.

The specialist in otology need not apologize for bringing the subject of chronic suppurative otitis to the consideration of a general medical society, since such cases would seldom come under the care of the aural surgeon unless they were referred by men in other branches of medicine. It is only within recent years that chronic suppurative ears have been turned over to the otologist unless an acute exacerbation or some intracranial complication made it necessary. An aural discharge lasting for months, or years, without pain, or occasional slight pain, came to be regarded as of little consequence, the seriousness of the condition being measured largely by the impairment of hearing which it occasioned. Fostered by the fact that it is not unusual for the discharge to suddenly cease on the advent of a serious complication, the idea that it is dangerous to check the discharge from a suppurating ear was formerly credited by many in the profession, and is still held by a majority, perhaps, of the lay public. An occasional irrigation of the canal for the purpose of cleanliness and lessening of the foul odor was all that was considered necessary or advisable.

Of late years, however, a majority of the profession, and, as a consequence, a large percentage of the public have come to realize the significance of a purulent otitis aside from its relation to audition. This has happened, I think, from two causes: In the first place, the specialist has rec-

ognized, and pointed out more clearly to the rest of the profession, that the majority of intracranial complications of otitic origin spring from cases of chronic otorrhœa. While the percentage of intracranial complications resulting from chronic suppurative cases may not be much over one per cent., yet, when they do occur, they are of such a serious nature that it is unwarrantable to neglect any suppurating ear which might be a possible cause. In the second place, insurance companies, quick to recognize this danger when it was pointed out, have refused to take risks on the lives of any who had a suppurative otitis. The proposition, then, that *no discharging ear should be allowed to go unchecked*, will not to-day be received with such vigorous opposition as it would have been even a decade ago.

It is one thing, however, to announce that a purulent discharge should be checked, and quite another to accomplish this end. The idea that simple irrigations, instillations, and insufflations are inadequate in most instances, must have forced itself upon all who have often had occasion to try them. How, then, shall chronic otorrhœa be treated? A careful inspection of the ear after thorough cleansing will reveal the fact, in the majority of instances, that the perforation in the membrana tympani is either too small or too badly placed to drain the tympanum. As a consequence the lining membrane constantly bathed in pus has become eroded and granulations or polypi have sprung up, which still further interfere with drainage; or bands of adhesion, running across the tympanum, have prevented drainage from the attic; or obstructions in the nose or nasopharynx (ecchondroses, exostoses, nasal polypi, hypertrophied turbinate bodies, adenoid vegetations), by causing a constant congestion in the ear, have kept up a continued discharge.

If all acute cases, when first seen, were properly treated by free paracentesis (and I mean by paracentesis a free incision of the drum membrane in the proper place instead of a simple puncture); good drainage secured and maintained, and any obstructions in the nose or nasopharynx prompt-

* Read at the meeting of the Harvard Medical Society of New York February 25, 1905.

ly removed, few cases of chronic purulent otitis would ever occur. However, many cases do not come to our observation until they are many months, or years, old, and it is to the care of such that I wish particularly to draw your attention.

Such a case should be thoroughly cleaned, carefully inspected, and the tympanum felt over with a probe, as far as possible, for necrotic areas. Should no necrotic area be found, if the perforation seems inadequate for drainage, a free incision should be made in the membrana tympani, and granulation tissue in the lower part of the tympanum removed with a curette; any adhesions which can be got at divided, and any obstructions in the nose or nasopharynx removed.

The external auditory meatus and all parts of the tympanum which can be reached should then be kept constantly clean by antiseptic irrigations, and mopping with cotton pledgets. I am convinced that better drainage can be maintained by the use of gauze wicks running from the incision out into a good sized dressing over the auricle, renewed once or twice in twenty-four hours, than by frequent irrigations.

Should the discharge seem to be lessening under this treatment, it may be persisted in for some weeks, if necessary, until the tympanum is free from pus, when the incision may be allowed to close. When, under such careful treatment, no improvement takes place, or, when at the outset necrotic areas of bone are found in the ossicles or low down in the tympanic walls, the membrana tympani, together with the malleus and incus, should be removed, and any areas in the tympanic walls which can be reached, and require it, carefully curetted.

This gives an opportunity of washing out the attic and affords more perfect drainage. Should this fail, or should there be evidence at the outset of necrosis in the attic or aditus, or should the tympanum be filled with a cholesteatomatous mass, or should there be a history of one or more acute exacerbations with pain and tenderness over the mastoid process, a so called *radical operation* should be advised.

This operation has gone through many phases, and different steps in it have been named after the men who first advocated it. It would be out of place for me to burden you with the details of the technique, although in practice most careful attention to some slight detail either in the operation or after treatment often makes the difference between success and failure. Whatever method is used, the object in view is the conversion of the tympanum, aditus, and mastoid antrum into a smooth cavity, the walls of which

have been curetted free from all necrotic areas, and the malleus, incus, and membrana tympani removed. A plastic operation is then made in the auricle which allows a free inspection of all parts of this cavity.

Subsequently, dermatization of the excavation is secured as soon as possible. The time for accomplishing this is materially lessened by the introduction of Thiersch skin grafts from the thigh or arm. I show some specimens prepared to familiarize you with the anatomy of the field of operation, and to demonstrate the size and character of the excavation. As you will see (see plates 1 and 2) the close proximity of the

FIG. 1.—Right temporal bone: vertical section of mastoid process. 1, tympanic membrane; 2, malleus; 3, incus; 4, tensor tympani muscle; 5, Eustachian tube; 6, facial nerve; 7, oval window with stapes in place; 8, superior semicircular canal; 9, carotid canal; 10, jugular bulb; 11, mastoid antrum.

lateral sinus, the middle cerebral fossa, and external semicircular canal, and the facial nerve to the field of operation, necessitates a very accurate knowledge of the anatomy of the temporal bone if one is to attempt it. With this knowledge, however, and the exercise of great care

FIG. 2.—Left temporal bone: deep excavation in mastoid. 1, external auditory meatus; 2, posterior wall; 3, superior semicircular canal; 4, external semicircular canal; 5, posterior semicircular canal; 6, sigmoid sinus; 7, facial nerve.

there is little danger of serious injury to any of these structures. As will be seen from the specimens, an entirely different excavation is made

FIG. 3.—Lines drawn tangent to circumference of bony canal posteriorly and superiorly; angle of crossing marks position of safety for entering mastoid antrum; probe passes through mastoid antrum and aditus ad antrum to tympanum; black line indicates area of bone removed in radical operation.

when symptoms of acute mastoiditis supervene on a case of chronic purulent otitis. Here instead of the comparatively small excavation shown as an ideal cavity (see plate 6), all the vertical cells and the tip are removed. As a consequence the posterior bony canal wall has to be lowered, as

FIG. 4.—Radical operation begun on the posterosuperior canal wall at the annulus tympanicus; bone outlined by black line, still to be removed.

shown in the other specimen, in order that the skin from the plastic operation may be turned into the bottom of the wound (see plates 7 and 8). In some of these cases I have left the bottom of the postauricular wound open for drainage for a week or ten days, instead of sewing it up completely, as is done in the usual radical operation. In this way a more deforming plastic operation on the auricle is avoided. In these cases I prefer

an angular flap made by cutting along the superior and posterior border of the cavum conchae, turning the skin into the bottom of the wound (plate 8), rather than some other flaps which have been suggested. In the usual case I prefer a tongue flap (plate 9), carried up and back into the excavation. The cartilage is dissected from the skin in both cases.

I show you two cases in which the tongue flap

FIG. 5.—Radical operation begun by entering mastoid antrum first; the bridge of bone indicated by black lines still to be removed.

has been used, one entirely cured, the other in an earlier state. The third case is one in which an acute mastoiditis had developed on a chronic condition. It proved on opening it to be a perisinus and epidural abscess. The posterior wound was left open for two weeks, and then, when the in-

mity in the ear would be noticed by a casual observer.

These cases should all recover in from four to twelve weeks. Some cases may last longer than

FIG. 8.—Plastic operation where the mastoid cells are all removed. An incision is made along the superior and posterior borders of the cavum conchæ, and the flap turned into the bottom of the wound.

FIG. 9.—Operation most suitable in cases where the ideal long excavation can be made; parallel incisions beginning in the cartilaginous canal and extending back to the posterior border of the cavum conchæ; the tongue flap is carried upward and backward into the excavation.

this, and may require a second or third operation; but they are exceptional, if careful attention to the technique and after-treatment is carried out, and all of them are practically free from danger of intracranial complications, after operation, even if the discharge is not stopped as quickly as anticipated.

254 MADISON AVENUE.

Fighting Tuberculosis in Cleveland.—The Cleveland Anti-Tuberculosis League is striving to find ways and means of diminishing the ravages of consumption by turning its attention to the causes of the disease among workingmen. Max Hayes, who is chairman of the dangerous trades committee, said that tuberculosis is most prevalent in those trades where fine particles of metal, stone, or lint fly about as in stone cutting, metal polishing, brick laying, cigar making, and garment manufacturing. In response to a question as to what could be done to remedy the conditions, Mr. Hayes said: "The working class need shorter hours; that this will cause a halt in the advance of the disease was shown by the cigar-makers, who reduced consumption in their ranks 50 per cent. by the reduction of the working day from ten to eight hours. Fresh air must be introduced into the shops. The blower law in metal working and stone cutting shops ought to be enforced. This law provides for a steady circulation of air which keeps down, or carries out, flying particles. In every trade some plan can be introduced to remedy conditions. It is our intention to get all the trades interested, and then make general demands."

SPONDYLOSE RHIZOMYELIQUE; A STUDY OF THE RELATIVE FREQUENCY OF SPINAL INVOLVEMENT IN RHEUMATOID ARTHRITIS, WITH AUTOPSY FINDINGS.*

By D. J. McARTHUR, M. D.,

PHILADELPHIA,

PROFESSOR OF MEDICAL JURISPRUDENCE, UNIVERSITY OF PENNSYLVANIA; ASSOCIATE IN THE WILLIAM PEPPER CLINICAL LABORATORY; VISITING PHYSICIAN TO THE HOME FOR INCURABLES, ETC.

Rigidity of the spine has in the last few years attracted considerable attention from clinicians. References to this condition are found scattered through the literature of the last century, but little attention was paid to it as a separate pathological condition until v. Bechterew published his paper, in 1893. This was followed by papers by Marie, Strümpell, and Bäumlér, and in the last two years a large number of cases have been placed on record. It is very evident from a study of these cases that several different diseases, with local manifestations referred to the spinal column, have been classed under the same general heading. It will be my aim in this paper to consider rigidity of the spinal column occurring as a separate and distinct clinical and pathological entity and rigidity of the spine as a local manifestation of rheumatoid arthritis.

The disease described by v. Bechterew is localized in the spinal column without involvement of other joints. It may affect a part or the entire spine. In the latter case there is a kyphosis affecting the upper dorsal and lower cervical vertebræ. There is an absence of the anterior curve of the spine in the lumbar region. The result of this rigidity of the upper spine together with the kyphosis gives the patient an appearance as if the head was pushed down into the shoulders and at the same time a forward extension of the neck. The rigidity of the lumbar spine, with the absence of the normal curve in this region, produces a peculiar attitude and gait. He stands with the legs partly flexed at the hips and knees and with the feet and legs rotated decidedly outwards. In all movements of the trunk the spine acts as a single bone, remaining in all attitudes perfectly fixed.

To these symptoms, all of which are due to the fixation of the spinal column, there is added in many cases a group of sensory symptoms referred by v. Bechterew to the spinal roots.

Subjective disturbances of sensation are present in the extremities, especially the upper ex-

trémities, such as pain and paræsthesia. Pain referred to the abdomen is not infrequent. Increase of reflexes occurs in the lower extremities associated with cramps in the legs. Impairment of sensation is found in the lower cervical and upper dorsal distribution, and also some atrophic wasting of the muscle groups in this region. The electrical examination shows no other change than a slight quantitative diminution. As ætiological factors, trauma, probably with concussion (*Erschütterung*) of the spinal column and heredity have been suggested. The following case belongs to this type of disease, and I report it here to contrast it with the cases of rheumatoid arthritis in which the spinal column is involved:

CASE I.—C. W., aged 34 years, white, weaver by occupation (but in early adult life an acrobat), was referred to me in September, 1899, for persistent pain in the abdomen and rigidity of the spinal column. His grandfather and uncle had had paralysis for several years before they died. He had two healthy children; his wife had had two miscarriages; otherwise his family history contained nothing of importance. As a child he had the usual diseases of childhood; acute articular rheumatism with a cardiac complication at 12 years, and gonorrhœa at 20 years. He had Texas fever, with a "bloody flux," from which he recovered and remained in good health until eight years previously. At that time while descending a small flight of stairs he missed his footing and fell some distance, landing on his feet. At that time he felt considerable pain in the right hip. This disappeared in a short time and he had no further trouble until over a year later. Pain reappeared in the right hip and for the past six years he had had more or less pain in both the right and left hips and at times over the lumbar and lower dorsal spine. This pain was a dull ache; much worse after several hours' work at his trade of weaver, which necessitated more or less forward and backward movement while in an upright position. At night he stated that he could hardly straighten up. His main complaint for the previous two years had been that of a constant pain referred to the pit of the stomach; he stated that "it felt as if there was a brick in the abdomen and as if the anterior wall of the abdomen was stuck fast to the spine." For the past two years he had had frequent nocturnal seminal emissions with night sweats. His memory had been failing for the past year. He was a sparsely built man with the typical flexed attitude at the hips and knees; a sunken, forward position of the head; and a rigid, awkward gait, with the toes adducted and the legs separated and flexed. The dorsal and lumbar spine was rigid and there was present only very slight forward movement in the cervical region. There was no ankylosis or other involvement of other joints. The erector spinæ group of muscles were hard and boardlike and somewhat wasted. The scapular groups were also wasted and hugged closely

* From the William Pepper Clinical Laboratory, Phœbe A. Hearst Foundation.

the underlying structures. He swayed more with the eyes closed than would a normal person. The knee jerks were present only on reinforcement. All the reflexes of the lower extremities were diminished. The reflexes of the upper extremities were normal.

Sensation over the extremities, normal; over the trunk there was hyperæsthesia in areas, more marked over the lower part of the abdomen. He was not sensitive to pressure over the nerve trunks. The hips were freely movable and not painful on motion or to direct pressure. Percussion over the dorsal and lumbar spine produced pain.

Visceral examination revealed an old mitral regurgitant lesion with an associated enlargement of the heart in full compensation; a moderate grade of atrophic emphysema with very impaired respiratory excursion and respiration mainly abdominal in type.

We had therefore in this case symptoms almost if not entirely confined to the spinal column and its supporting muscles and to the nerve roots. There was no trace of disturbance in the extraspinal articulations and the symptoms referred to the spine developed insidiously and were progressive in character. The diminution of the leg reflexes, associated with the early subjective symptoms referred to the lower extremities, might be explained by the fact that the spinal process in this case was ascending in type and whatever damage to the roots may have taken place would more likely be further advanced in the legs than in the upper spinal distribution. The most interesting thing about this case was the long duration of what was evidently a chronic joint affection remaining limited to the spinal column. The abdominal pain and the pain in the extremities in the absence of any other lesion must be referred to the spinal roots.

If the other symptoms recorded did not occur in typical cases of rheumatoid arthritis I should have been disposed, on account of the course of the disease (extending over eight years), and its strict limitation to the spine, to class this case as a distinct clinical entity apart from rheumatoid arthritis. The following case is of considerable interest in this connection:

CASE II.—J. R., male, aged 11 years, was admitted April, 1901, suffering with acutely swollen painful joints. He had had measles at the age of 5 years, but had otherwise been healthy. The present trouble started in March, 1900, with swelling of the feet and knees, with pain and tenderness. In July the hands were affected in the same way. On admission the wrists were markedly swollen, but were not painful to ordinary pressure. Fluctuation was present in both wrist joints. Grating was likewise observed. The joints of all the fingers were similarly affected. The metatarsal articulations of both great toes were enlarged and tender. The blood count at this time showed R. B. C., 6,000,000; W. B. C., 14,000; Hg., 60 per cent. There was a systolic murmur over the aortic cartilage transmitted into the vessels of the neck. At my last examination during the past spring all the joints of the

extremities were more or less ankylosed. The spine appeared to be involved throughout its entire course. In the cervical region there was little motion left, but not complete ankylosis. The ankylosis was much more extensive in the dorsal spine and to a lesser degree in the lumbar region. There were distinct symptoms of root involvement. Wasting about the shoulder girdle and in the extremities, zonal hyperæsthesia on the trunk, and an atrophic condition of the skin in the area of the affected joints were noted.

This case was of considerable interest on account of the early age at which it developed and the sensory and reflex symptoms indicative of root and spinal involvement.

The following cases will give some idea of the frequency and extent of spinal involvement in rheumatoid arthritis:

CASE III.—J. S., male, white, aged 34 years. Occupation, fireman. All the joints were ankylosed, the patient being rigid; the entire spine was rigid and immovable. It was necessary to feed with liquid or semiliquid food.

CASE IV.—D. M., male, 35 years old; song and dance artist. The disease began with an acute attack of pain and fever ten years previously; this was followed after a year's quiescence by a progressive involvement of all the joints, beginning in the right upper extremity and extending to all the joints of the body. The maxillary joints were but little affected. The spine was rigid with marked tenderness throughout its entire extent; there was some movement present in the cervical region. A marked kyphosis affected the dorso-cervical area.

CASE V.—K. M., female, aged 53 years; housewife. An acute attack of pain and swelling began in the hands twenty-six years before, and extended to all the joints of the extremities, which later became ankylosed. The spine was almost rigid in the dorsal and lumbar areas, but quite movable in the cervical area; no curvature or tenderness.

CASE VI.—M. W., 49 years old; housewife. The disease began with an acute attack twenty-one years before, and gradually affected all four extremities, the dorsal and cervical vertebrae; lumbar spine not affected; some slight kyphosis in the upper dorsal area; cervical area and all the affected joints very tender.

CASE VII.—T. C., male, aged 31 years, occupation, brick maker. The acute attack began fourteen years before with severe pain in lower extremities. Some time after this he fell and injured his spine and has not since been able to walk. Symptoms referable to the spine became much more marked after the injury. The disease progressed in the other joints until at the present time there is practically complete ankylosis of all the joints, including the jaw joints. There is some kyphosis with tenderness and pain referred to the cervical region; marked arterial sclerosis

with a systolic murmur over the apex of the heart.

CASE VIII.—M. E., male, aged 33 years, farmer. Acute attack occurred seventeen years previously, affecting ankles and knees; joints of lower extremities markedly involved and to a lesser degree those of the upper extremities; jaws also involved; complete rigidity of the entire spine; considerable pain present with tenderness; slight lateral curvature in cervicodorsal area.

CASE IX.—M. S., female, 68 years old, housewife. Acute attack began thirty-two years before in the right shoulder and wrist; since that time all the joints had become more or less involved; vertebrae were all involved with some tenderness in the lumbar region and some slight lateral curvatures in the cervicodorsal; process most intense in the cervical area.

CASE X.—F. R., male, aged 36 years, soap worker. Acute attack began thirty-five years before with involvement of the hands; history of injury in the hand and arm first affected; main involvement found in the upper extremity; some crepitus with pain in the joints of the lower extremity; recent involvement of the cervical area of the spine; dorsal and lumbar areas completely ankylosed; an area of zonal anaesthesia corresponding to the scapula of the right side; some tenderness with a slight kyphotic curvature in the cervicodorsal area.

CASE XI.—M. W., female, aged 64 years, housewife. Acute attack occurred twelve years before after an attack of grippé. The lower extremities were at first affected. This was followed by rigidity of the spine and later of the lower extremities. The affection of the spine was confined to the cervical and upper dorsal areas. The lumbar spine was little if at all affected. There was some anaesthesia of the trunk in the middorsal distribution of the right side.

CASE XII.—M. T., male, aged 63 years, carpenter. Acute attack began fourteen years before, following grippé. The ankles were at first affected, later the joints of the lower extremity. He had had "lumbago" ever since the beginning of the disease. The main involvement of the spine was confined to the dorsolumbar area; there was considerable crepitus with comparatively little limitation of movement in the cervical area. There was an area of anaesthesia of the trunk corresponding in distribution from the sixth to the tenth dorsal spinal segments with a zone of hyperaesthesia above this area.

CASE XIII.—M. W., female, aged 49 years, housewife. The acute attack began twenty-one years before, after the birth of a stillborn baby. There was an acute painful swelling of the joints with fever affecting both upper and lower extremities. There was very marked atrophy of the muscles and also of the skin; marked deformity in all four extremities; spinal involvement confined to the cervical and upper dorsal areas, associated with distinct scoliosis and some kyphosis in the same area.

CASE XIV.—This patient had been under my care at the Home for Incurables, and was later admitted at the University Hospital, where he died and where the autopsy was performed. I am indebted to Dr. Stengel for his notes of the case and for the autopsy material.

D. M., aged 32 years, white, admitted to University Hospital January 17, 1902, service of Dr. Stengel; electrician; occupation necessitated use of right hand a great deal; used alcohol moderately; father died of pleurisy; mother and one sister living and well; no history of injury; never had any sickness except present trouble. Eight years before, patient began to have pain and stiffness in the right wrist. The fingers of the right hand were involved in a few weeks, and successively the wrist of the left hand (not as marked as the right); this was followed by an involvement of the ankles, feet, knees, hips, and spine. He had been at the Home for Incurables for the previous two and a half years. Until admission to the hospital he was able to walk with the aid of a cane, and to sit in a semierect position in a high chair.

Physical Examination: Lay in bed on back, semirecumbent, legs and thighs flexed; he asked frequently to be lifted higher on pillows; could sit on side of bed with hips partially flexed; apparent age forty-five years; gait not noted; facies, expressive of tremendous emaciation. Bony structure that of a man of moderate size and development. Skin dry, glazed, and shiny, especially over ribs; on abdomen showed superficial scaling. Brownish pigmented patches on ring and small finger of right hand, and ring finger of the left hand; slight on forehead; oedema marked in feet. No abnormal pulsations or eruptions. Temperature: local not elevated; general, 98.2° F.; superficial arteries slightly sclerosed; no lymphatic enlargement; muscles markedly wasted; strength very poor; muscles appeared to have been of moderate development; tremors slight; no contractures; nails show marked linear striation.

Joints: Right thumb and middle finger subluxated; little finger fixed; right wrist joint fixed; left wrist movable. Elbow motion good. Shoulder motion limited, could not raise arms to horizontal position; anteroposterior motion also limited; neck very rigid; spine showed impaired motion. Great toes fixed in hammer toe position; second toes fixed, remaining toes showed impaired motion. Limitation of motion in articulations of tarsus. On right side reversal of anteroposterior arch of foot, convexity downward. Right knee spindle shaped, enlarged, motion limited. Left knee, moderate motion; left hip, motion good; right hip, fixed. Head, angular in shape, size proportionate to body. Hair dry. Face showed signs of wasting, sunken eyes, hollow cheeks and temporal fossae, prominent molars, chin, and nose, thin lips. Color, slight pigmentation on forehead; pallid. Eyes, dark brown; size normal, pupils reacted to light and accommodation; conjunctivae slightly congested; sclera, pale. Ears, large, no abnormality in shape; mastoids prominent; hearing good. Jaws showed some

impairment of motion; lips thin, dry, and pale. Mouth and nose, mucous membrane pale; breath, foetid; teeth, few and carious; gums pale; tongue dry whitish coating, movements good, marked tremor. Palate, tonsils, and pharynx slightly congested; voice, slightly hoarse; vocal cords not examined; neck thin, motion restricted; carotid pulsations not marked; no thyroid enlargement; lymphatic glands not enlarged. Thorax: All normal depressions very marked from emaciation. Respiratory movements limited, breathing largely abdominal from lack of mobility of costal and spinal articulations. Apex beat fifth interspace one and one half inch within nipple line; pulsation visible in fourth interspace; no thrills; fremitus marked on both sides. Lungs: Percussion showed apex to be level with clavicle; base at sixth rib on left side; very slight descent with inspiration; percussion note not appreciably impaired. Heart: Upper border at lower edge of third rib; right border, slightly within right border of sternum; apex, one and one half inch within nipple line, fifth interspace. Auscultation sounds clear, but weak; no murmurs; cardiac action irregular. Abdomen: No thorough examination; walls very rigid. Liver enlarged, one inch below costal margin. Gastric area extends as low as umbilicus. Spleen not palpable. Nervous system: Gait not noted; coordination impaired from condition of joints, and weakness; slight tremor, largely volitional. Muscular strength impaired, equally decreased on the two sides. Reflexes: Patella, biceps, and triceps increased. Sensation: Tactile not appreciably impaired; sight, hearing, and speech normal; some mental impairment and irritability.

Blood: Hæmoglobin 38 per cent.; R. B. C., 5,130,000; W. B. C., 21,200.

Urinalysis: Urine slightly cloudy, pale yellow, neutral, no precipitates; sp. gr., 1013; albumin, distinct ring with HNO_3 ; sugar, negative; indican, distinct. Cystoscope showed urates, epithelial cells, a few leucocytes, and hyaline and granular casts.

Pathological Examination.—No gross changes were observed in the central nervous system. Microscopical examination of the brain showed a moderate grade of arteriosclerosis. The large cortical pyramidal cells of the motor cortex were the seat of senile changes, i. e., they were of somewhat smaller size with a diminution in the number of dendrites, a lessened quantity of chromatin, and a deposition of yellow pigment at one extremity of the cell. This deposition of pigment in some of the cells occupied a greater portion of the cell area. In such cases the nucleus took a somewhat eccentric position. These changes are normal to old age, and occurring at an earlier period of life in cases of marked arteriosclerosis are simply indicative of presenility. These changes occasionally occur in conditions of intense intoxication. I have observed them in a case of diabetic coma.

A microscopical examination of the spinal cord showed the same cellular changes as observed in the cortex. There was also a condi-

tion of arterial sclerosis of the vessels of the cord, with miliary aneurysms. Two miliary aneurysms, one in the area of the crossed pyramidal tract of the cervical area of the cord, the other in the anterolateral tract of the upper dorsal area, were observed. Small areas of perivascular sclerosis obtained here and there throughout the cord. The areas were not uniform around all vessels and occurred only around certain vessels, and like the miliary aneurysm formation, were in the distribution of the pial vessels, i. e., not in the distribution of the anterior spinal artery and its branches. There were small black granules scattered here and there over the entire area of cross section of the cord by the Marchi method. Inasmuch as a few sparse black granules may occur in normal conditions as a manifestation of nutritive changes within a normal limit an increase in the number of these fat granules is, I take it, merely the accentuation of the same nutritive changes in the myelin, due to the arteriosclerosis. The same condition obtained in the nerves. In the longitudinal section of the nerves these black granules were present, but not sufficiently frequent to constitute degeneration, i. e., the myelin formed a continuous entity between the nodes of Ranvier and the minute black granules which were occasionally present, never occurred as a continuous row of black dots, such as would necessarily be present if the nutritive changes in the myelin were sufficiently intense to constitute a pathological process. While, therefore, I consider the presence of those conditions both in the spinal cord and peripheral nerves as within the normal pale, it is only so here described within such limits. When the arterial changes are taken into consideration I should not consider them entirely normal in a man thirty-two years of age, but abnormal only in the sense of deficient nutrition due to arteriosclerosis.

In a cervical and lumbar enlargement of the cord, the ganglion cells of the anterior horns were diminished in number and the seat of the following changes: The yellow pigment occupied a large part of the cell area with an eccentric position of the nucleus and diminution in the number of dendrites. The nuclei of most of these cells were of much smaller size and stained very deeply with the nuclear stain. The nucleus with the hæmalaun-eosin took a pale violet tinge, in which the filaments of chromatin could be seen under a high power. In the cells under consideration the nucleus was reduced to one half or even one third of the normal size, took a deep purple stain, in the midst of which the nucleolus was hardly perceptible. In a few of the cells the nuclear area was so reduced as to form a very slight ring around the nucleolus. The other ganglion cells, both in the cervical and lumbar enlargements, were fewer in number than in normal cords.

The anterior and posterior roots were normal by the Van Gieson, hæmalaun-eosin, and Weigert stains. By the Marchi method, the posterior roots showed a number of small black granules, both in transverse and long section, but not sufficient to constitute unquestionable degeneration. This was borne out by the fact that secondary

FIG. 1.—Miliary aneurysm in the anterolateral tract of the spinal cord of Case 13. This aneurysm involves one of the pial arteries. Rarefaction and an area of sclerosis are seen around the aneurysm.

FIG. 2.—Section with the exception of "E" stained by "Haemalaun-carbolic-eosin" stain. A A, Normal cells. B, Eccentric position of nucleus, with diminution of its size. C, Marked diminution in size of nucleus. The nucleus has taken very deep stain. D, Atrophy, with pigmentation of the cell and with shadow nucleus. E, Perinuclear pigmentation, as shown by Marchi method.

degeneration was not seen by the Weigert method, other than as a slight perivascular sclerosis, in the posterior column. In such a chronic process this would undoubtedly be present had this degeneration gone beyond the limits of a functional and restorable process.

The changes in the spinal intervertebral ganglia, other than the marked arteriosclerosis of the vessels, were confined to the ganglion cells. The normal ganglion cells should be spherical with a large vesicular nucleus, staining a very pale violet with hæmalaun, with the cell substance staining a light purple. The chromophilic bodies of Nissl were distinctly stained and were in these cells finely granular and absent at the periphery of the normal cells. In the ganglia of this case, it is exceptional to find a cell approaching the normal. The yellow pigment described was present in these cells in large quantities. In some of the cells it appeared as a dark yellow homogeneous mass, whereas in others it occurred as very fine granules, giving a pale yellow tinge to the cell protoplasm. The arrangement of the pigment in the spinal ganglion cells was somewhat different from that observed in the cells of the spinal column. The usual arrangement of the pigment in the spinal cells is toward one end of the cell. In the spinal ganglia the deposition of pigment as a rule is around the nucleus in the centre of the cell. This is brought out very distinctly in sections by the Marchi method. The granular pigment in this case, both in the cells of the spinal cord and of the spinal ganglia, gave a black stain by the Marchi method and a purplish black stain by the Weigert sheath stain. The same character of pigmentation with more advanced changes in the nuclei and other evidence of senile degeneration of the cells, both of the spinal cord and intervertebral ganglia and the Gasserian ganglion, were present in a case of migraine with extensive arteriosclerosis of the central nervous system. In some of the cells, instead of a deeply stained contracted nucleus, the nuclei were very pale without nucleoli and without the chromatin filaments of the normal nucleus. The chromophilic elements of the cell protoplasm stained less intensely in these cells, especially towards the periphery of the cell. The outline was somewhat irregular in shape. In more advanced stages of degeneration the cell outline is very irregular, the cell protoplasm taking a homogeneous pale violet stain with a deposition of large quantities of yellow pigment at one side and sometimes taking up the entire cell area; the nucleus is either entirely absent, or if present has an eccentric position at the edge of the cell and at times appears as a vacuolar area in the midst of a mass of pigment, but taking no stain and appearing as a clear, stainless area.

All these cell changes have been noted as occurring in the intervertebral spinal ganglia, and are also present in the Gasserian ganglion.

An examination was made of the sciatic nerve and two similar nerves sent to the laboratory unlabeled. The examination of the sciatic nerve by the Marchi method showed no distinct, well defined degeneration, merely the presence of small black granules here and there as described. The

examination by the Weigert sheath method showed distinct degeneration in small groups of fibres. This degeneration was not that of individual fibres, but of a number of contiguous fibres running parallel in the same area of the nerve. This was best seen in microscopic sections cut in the long axis. The muscles were not submitted for examination.

The pathological lesions described in this case, i. e., the cell degeneration of arteriosclerosis and the changes in the peripheral nerves, have been found in other conditions. I have noted before the same cell degeneration in a case of migraine with arteriosclerosis of the nervous system and have also seen it in other cases of arteriosclerosis. The same group of lesions identical with all those described are present in a case of paralysis agitans with joint deformity.

The similarity of certain cases of paralysis agitans to the ankylotic form of rheumatoid arthritis is very striking. Spiller has recently called attention to this same condition. I have been impressed of this similarity for a long time, and Dr. Carncross, in an investigation of my cases at the Home for Incurables, both of rheumatoid arthritis and paralysis agitans, has noted in a number of cases a distinct identity of joint and sensory symptoms. The lesions of the sensory ganglia (the spinal and Gasserian) are of especial interest in their relation of chronic trophic disturbances. The association of disturbance of the sensory system to both acute and chronic trophic disturbance, has not received the proper attention. I have called attention to it in hydrophobia, for my attention had first been directed in this direction by Dr. Burr's observation at the Philadelphia Hospital of the rarity of trophic necrosis without sensory derangement. The atrophy arrangement in the muscles and other tissues in direct association with diseased joints, so called Charcot reflex atrophy, is similar, although not so extensive as the trophic disturbance in the same structures in rheumatoid arthritis. It is probable in cases of reflex atrophy following a joint injury, that a functional or organic disturbance of the sensory neurone, such as is described in this case, may be the explanation of the condition. The findings in these cases, if they teach anything, support the theory of an affection of the central nervous system for the cause of rheumatoid arthritis; that these lesions, however, may be secondary to the joint changes should not be lost sight of, especially as we see an identical symptom complex developing in the course of tuberculosis which may more easily explain the theory of a local pathological process in the joints.

In drawing conclusions from the cases here reported, it must be remembered that all of these cases, with the exception of Case I, are of long

standing and exhibit an advanced state of the disease. Notwithstanding this fact the frequency of the spinal involvement is striking. There is, however, no special reason why the spinal articulations should not be affected with the same frequency as the other joints. The fact remains that these joints are rarely involved in acute articular rheumatism. In Case I during the period of the initial acute stage, symptoms referable to the spine were not present, or at least were not spoken of by the patient, and yet within two years well defined and apparently advanced rigidity of the spine was presented on examination. The presence of root symptoms in this case, flattening of the chest, etc., gives us a clinical picture if the other joints are left out of consideration, almost if not exactly identical with that in the group of cases described by v. Bechterew.

The history of the case of isolated spinal rigidity (C. W.) deserves careful comparison with those here tabulated. In all the cases of rheumatoid arthritis there is a well defined history of acute manifestations in the joints followed at varying intervals by the progressive joint changes and at times with acute exacerbations of the chronic symptoms. In all the cases here reported of rheumatoid arthritis in which the spine is entirely involved, there is an extensive involvement of nearly all the other articulations, even the jaw joints in some of the cases being affected. In the case of C. W. the onset was insidious, without acute symptoms, and followed some time after a shock to the spine. The initial symptoms in this case were referred to the legs and in all probability were of root origin. The immunity of the other joints after ten years of progressive stiffening of the spine is noteworthy.

In spite of the similarity of the joint symptoms in some of the cases of rheumatoid arthritis to the disease described by v. Bechterew, we are not at all positive that the latter disease is in all cases or even in the case here under consideration to be considered as being a local manifestation of rheumatoid arthritis. One should be careful about arriving at positive conclusions in such a matter, inasmuch as it is highly probable that a group of etiologically distinct joint affections are classified clinically under the term rheumatoid arthritis. From a study of the cases at our disposal we are justified in drawing the following conclusions:

(1) That ankylosis and rigidity of the spinal column is a frequent manifestation of advanced rheumatoid arthritis.

(2) That it may develop early in the course of the disease and be associated with irritative root symptoms.

(3) That if the disease described by v. Bechterew is to be considered as a distinct clinical entity separate from rheumatoid arthritis, it should only be diagnosticated as such after the disease has progressed over a considerable period of time without involving joints other than those of the spinal column.

(4) That we are not able at present to differentiate from rheumatoid arthritis that large group of cases, reported by Marie and others, where the rigidity of the spine is associated with changes in the hip and other joints.

ASEPSIS AND ANTISEPSIS IN OBSTETRICS: ALSO "STERILE GAUZE" AND "STERILE WATER."*

By J. MILTON MABBOTT, M. D.,

NEW YORK,

ATTENDING OBSTETRICIAN, NEW YORK INFANT ASYLUM;
GYNECOLOGIST, OUT-PATIENT DEPARTMENT,
NEW YORK HOSPITAL.

We feel constrained to call attention to the fact that the word *asepsis* simply means *without sepsis* and does not mean *without antiseptics*. The definition of asepsis is absence of blood-poisoning, exemption from putrefaction and its consequences. A title quoted from Dr. J. C. Warren, *Use of the So Called Germicides in Efforts to Procure Asepsis* serves well to illustrate the meaning of the word. (*Standard Dictionary*.)

We frequently hear the terms *aseptic* and *antiseptic* loosely employed in relation to practice, as if the one implied the exclusion of the other, whereas both refer to methods aimed at the exclusion of infection, and antiseptics afford the surest means of securing asepsis.

Recently we were somewhat shocked to have our urgent appeal for immediate perineorrhaphy on correct mechanical principles,¹ read before the New York County Medical Society, vigorously opposed in the discussion by a medical gentleman who fears perineorrhaphy on account of the danger of sepsis. The gentleman in question has since circulated a reprint of his remarks as reported in the *Medical Record*, and we find that he deliberately leaves a ruptured perineum unprepared for the reason stated, while availing himself of no more efficient means of securing asepsis than "soap and hot water," with which one should "first scrub; second scrub; and third, scrub." He fails to inform us whether he uses three kinds of soap. And we strongly protest against being misunderstood as implying that we think he uses too much soap and

water. A soap solution is weakly antiseptic. Neither do we deny that very good results can be secured without the use of any other antiseptics. We simply contend that the best results cannot be so obtained.

There is no question whatever of the danger of sepsis being greater in an infected closed wound than in an infected open wound. And since we believe that microorganisms in the contiguous skin or air are occasionally responsible for infection, we too should have some hesitation in sewing up the perinæum without disinfection even in a cleanly conducted case. But why should we not cleanse the wound with an antiseptic solution and seal it from later infection? So far from being a cause of sepsis perinæorrhaphy thus becomes a valuable means of prevention. While there is one practitioner openly advocating the open treatment of the perinæum, the subject is worthy of our attention lest others be misled.

We desire right here to say a word about "sterile gauze" and "sterile water."

How long does gauze remain sterile after the unavoidable exposure to the air incidental to its removal from the sealed container and introduction into a wound or cavity? We have seen the uterus packed with "sterile gauze" after curettage in a mild case of puerperal septicaemia and at the end of twenty-four hours the gauze had a putrid odor much more offensive than any which had existed before, the patient in the meantime exhibiting no amelioration of symptoms. The gauze was removed and improvement rapidly followed.

Even though gauze be impregnated with an antiseptic, if its meshes contain air it may actually prove a source of infection. The uterus is a natural incubator. Therefore, avoid using gauze in the puerperal uterus or vagina except where packing or drainage seems very important, and when used remove it at the earliest permissible moment. Packing of the puerperal uterus either after abortion or later delivery is seldom if ever indicated. The cervix usually remains sufficiently open for drainage.

"Sterile water" exposed to the air is sterile only while it is too hot for any use in midwifery. By the time it has cooled sufficiently for use many microbes have fallen into it from the atmosphere and remain undestroyed at the lower temperature. Sterile water in sealed containers cannot be utilized without at least momentary exposure to the air. In the earliest post partum period, a few drops of such water left in the vagina or uterine cavity may be responsible for the sepsis seen a few days later. Admixture with blood forms an ideal culture medium. The puerperal uterus and genital tract probably present a better soil for infection than any other tissue or organ of the body. There is a vast dif-

ference between the puerperal uterus and the uterus not recently the seat of pregnancy. One part of corrosive sublimate in ten or twelve thousand of water will keep the water sterile when cool. A small quantity retained in the uterus or vagina will be harmless. It is obvious that no deductions from recent experience in dealing with the peritoneal cavity are applicable to the puerperal uterus and vagina. While we have reason to believe that the atmosphere ordinarily contains germs which may drop into sterile water at the moment of use and possibly cause puerperal infection, let us give our patient the benefit of the doubt as to whether Nature may be able to take care of the microbes. Let us do it for her. Our means of securing asepsis are far more certain when they include the moderate, rational use of an efficient antiseptic. Even our most scientific methods are imperfect. Dr. Brodhead has recently published a paper,² going so far as to advise abstention from all internal examinations during labor in cases previously ascertained to be normal, so long as they seem to be progressing favorably. Such extreme conservatism seems unnecessary to one who as yet has never lost one of his own patients from sepsis. But Dr. Brodhead's anxiety should at least serve to emphasize the importance of employing rigid antiseptic methods. On an occasion like this a little review may not be out of place.

Preliminary care of the patient during the early part of labor includes the usual bath, enema, and clean clothing. The hair of the pubes and neighboring parts should be clipped short with scissors so that there will be no danger of any hair reaching into the vulva later. The skin of these parts including the roots of the hair will be soaked with an antiseptic solution before making a vaginal examination (as stated hereafter) and also occasionally as labor progresses even though no examinations are made. Clean sheets, draw sheet, bed pads, or Kelly pad are employed as usual.

The hands of the attendants should be thoroughly scrubbed with soap and warm water for at least five minutes, and immersed in an antiseptic solution for an equal length of time. Wipe out under the finger nails with a little gauze or absorbent cotton wet with the solution. When late arrival does not allow sufficient time for such preparation, rubber gloves should be worn, or the hands should at least be dipped in an antiseptic solution and religiously kept out of the vagina and away from abrasions or a lacerated perinæum until properly scrubbed at the earliest opportunity.

Ordinarily a bichloride solution, 1 to 2000, is sufficient and suitable for all external purposes, and a 1 to 4000 solution internally. Where there is

² *Medical Record*, April 24, 1904.

reason to fear specific or special infection we use solutions twice as strong. Lysol, one or two per cent., keeps the examining fingers and mucous membranes slippery and is therefore useful where repeated examinations are made. Lysol is not trusted alone, but is used after the hands have been soaked in the bichloride solution. Petrolatum and other lubricants are seldom necessary.

Before making an examination, the vulvar canal and neighboring external parts for several inches in every direction, including the mons veneris, should be bathed with the antiseptic solution, using always for this purpose fresh "sponges" of absorbent cotton, as many as may be required, having a fresh solution with several such pieces of cotton in a basin within reach, either on the foot of the bed or on a chair or table near by, never dipping the cotton a second time into the solution, but dropping it after use into a slop jar or other receptacle. The preputium clitoridis should be drawn back and carefully cleansed, and creases between the labia majora and minora and all folds about the vaginal orifice which can be exposed to view should receive similar attention, the knees being drawn up and widely separated. Even where the final delivery is to be conducted in the left lateral decubitus, all this preparation should be done with the patient on her back.

The vulva should be wet with the antiseptic solution the last moment before examination. Both hands of the obstetrician (with or without gloves) are likewise wet by dipping them into the solution, and two fingers of the examining hand are introduced into the vagina, avoiding contact with apron, towel, or anything whatsoever, no matter how sterile, even the labia being held widely apart by the thumb and fingers of the other hand. With these precautions no vaginal douche need be employed in normal cases either before or after delivery. A single vaginal douche is usually given after instrumental delivery or perinaeorrhaphy; also at the end of a tedious labor, especially if there have been unusual manipulations. Forceps are boiled (or sterilized) immediately before use, and used out of the utensil in which they are boiled or a pitcher which has been disinfected with a 1 to 1000 bichloride solution and rinsed out with boiling water. Dipping them in a lysol solution will serve the double purpose of making them slip in easily and rendering a subsequent douche unnecessary.

Sterile napkins, or vulvar pads, as bought in sealed packages of reliable makers, or prepared and sterilized at home, are employed in the usual manner. A gas stove and fish kettle make an excellent sterilizer. Ordinary napkins fresh from the laundry are probably almost equally sterile and safe. Any napkin or pad must be looked upon as a neces-

sary evil and should be changed frequently, not less than five or six times daily during the first week after delivery. The mother should usually pass urine at these times, and the vulva should be bathed with a warm 1 to 2000 bichloride solution on each of these occasions. Bichloride tablets are so inexpensive that a fresh solution can be made every time. Antiseptic occlusion dressings have never seemed advisable.

In all cases, beginning with the second week after delivery we usually prescribe a mercurial vaginal douche (1 to 4000) once or twice daily to promote involution and on account of the grateful sense of cleanliness afforded to the patient. These douches may be discontinued when the lochial discharge ceases and napkins are no longer required.

In febrile cases and where the lochia develops the slightest bad odor, we do not hesitate at any time to employ vaginal or intrauterine douches, associated with digital exploration, considering such treatment absolutely indicated. The dull curette is believed to be a safe and necessary instrument in experienced hands and under certain circumstances.³ As an intrauterine douche it is customary to employ about two quarts of a warm 1 to 4000 (or 1 to 5000) bichloride solution, followed as part of the same douche by an equal quantity of fluid not more than half as strong. Such irrigation may be repeated at intervals of six or eight hours until the temperature of the patient remains under 101° F. (or even 100° F in some instances). The danger of poisoning from absorption is practically nil externally, very slight for the vagina, and very considerable for the uterine cavity. The last is greatest, of course, immediately after labor, when nothing stronger than a 1 to 8000 solution should be employed. Make sure that little or none is retained. Manipulate the uterus through the abdominal wall, and even let the patient be raised into a sitting posture for a few moments if necessary. Other antiseptics may be resorted to if the patient or practitioner exhibits an intolerance toward the bichloride of mercury. The physician may find antiseptics so injurious to his hands that he will adopt the use of rubber gloves. Rubber gloves are particularly useful in protecting the hands when it is necessary to examine a case already septic, and also as a safeguard to the patient if the skin of the doctor's hands is not perfectly sound and healthy. Small, fresh cuts on the hands should be disinfected with a bichloride solution, allowed to dry, and coated with flexible collodion.

Always warn a woman to keep her own hands away from the vulva while she is confined to bed. Let me add that this warning is not based on purely

³The indications for curettage have been admirably summarized in a paper by Dr. E. K. Brown, *Medical Record*, January 28, 1905.

theoretical considerations. During this period the bladder and rectum should not be neglected, and it is one of the exclusive duties of the nurse to render the necessary attentions. Sponge bathing and general cleanliness are presupposed, and the linen of the bed and patient may always be changed as often as desired.

19 FIFTH AVENUE.

A CLINICAL LECTURE UPON A CASE OF TYPHOID CHOLECYSTITIS.*

By J. CHALMERS DA COSTA, M. D.,
PHILADELPHIA,

PROFESSOR OF PRINCIPLES OF SURGERY AND PROFESSOR OF CLINICAL SURGERY IN JEFFERSON MEDICAL COLLEGE.

The first patient that I present to you to-day is a boy, eleven years of age, who was referred to us by Dr. James, of Mays Landing, N. J. There is nothing in the family history of this patient that has any bearing upon his present condition. He is said never to have had any of the ordinary diseases of childhood.

Two months ago he developed typhoid fever, which confined him to bed for five weeks. About a week after he had gotten up from bed (that is, something over two weeks ago), he developed severe abdominal pain in the right side, which was accompanied with nausea and constipation and was associated with a temperature of 104° . There were tenderness and abdominal rigidity, and the condition was regarded as due to appendicitis.

The severe pain quickly passed away, and after three days' confinement to bed, the child was about again, with a normal temperature and apparently entirely comfortable. After a few days he again complained of pain—this time distinctly in the right hypochondriac region. The pain came on rather suddenly; was not so violent as in the first seizure, and was accompanied with an elevated temperature, headache, thirst, nausea, constipation, and coated tongue. There was no vomiting. The tenderness was decided and the rigidity was marked. The next day the physician noticed that the child was beginning to become jaundiced. This was seen first in the whites of the eyes and afterwards spread rapidly over the rest of the body. Later, the stools were found to be clay colored.

During the next few days the child suffered from paroxysmal pain and grew gradually worse. He was brought to this city and admitted to the hospital.

The examination of the patient on admission showed that he was the victim of a general and very distinct jaundice. The pulse was 108; the temperature, 99.6° . There was marked rigidity of the upper portion of the right rectus muscle. The child complained of a little pain, but not much. At times there were paroxysms of pain. There was decided tenderness over the region of the gall bladder; and where as there was a general impression in our minds that there was a mass of some kind beneath, the rigidity of the rectus muscle prevented a certain conclusion.

The physical examination showed that the heart and lungs were normal. The leucocyte count was 10,400. The urine contained a trace of albumin and bile pigment, but no blood and no casts. A bac-

teriological examination of the blood was ordered, and the subsequent report showed that it was sterile and contained no malarial organisms. It showed, however, the Widal reaction strongly.

To sum up this case: A child had a distinct attack of typhoid fever, and when convalescent from the enteric fever, developed paroxysmal abdominal pain associated with elevated temperature, constipation and abdominal rigidity. This condition passed away, and was followed within a few days by a renewed attack, in which there was pain, tenderness, fever, rigidity, and well marked jaundice. The evening before his admission to the hospital the temperature was 103.6° and he lay upon his back with the legs and thighs flexed. The morning after his admission into the hospital, however, the temperature became normal; the spontaneous pain passed away, the tenderness greatly lessened, the rigidity became less distinct, the pulse slowed down a little, and the question arose whether this was a condition that was going to pass away without operation or whether operation should be undertaken. Between then and now we have carefully studied the patient. We have found that the symptoms oscillate. Some days the temperature is up, and some days it is down. One day it reached 104.6° and remained so for a few hours. Some days the tenderness is worse, and some days it is better. During the last two days, however, the rigidity has definitely increased, and the sensation of a mass has become more distinct, in spite of the rigidity. The leucocytes yesterday were found to have fallen from 10,400, which they were on admission, to 6,800; and we might conclude either that the patient is better or that the zone of inflammation is well encapsuled, or else that toxæmia has interfered with the leucocytosis. It is evident that there is not grave toxæmia and the general condition of the patient is certainly not better. Nevertheless, this is merely speculative, and I shall never allow the count of the leucocytes alone to determine my decision. The other symptoms are not better, although the leucocyte count has fallen.

What diagnosis shall be made in this case? We at once think of that protean malady, appendicitis. To be sure the pain and tenderness are not in the right iliac fossa, but occasionally appendicitis manifests itself in the right hypochondriac region. It does so when the tip of the appendix is near to or is attached to the gall bladder; it may do so when the appendix is high up back of the cæcum; or when, from lack of development, the cæcum has not descended, but remains in the gall bladder region. In the vast majority of cases, the signs of appendicitis are in the right iliac fossa. The attack of typhoid fever is not conclusive, as appendicitis may develop during and after typhoid. Jaundice is very rare in appendicitis, but may occur. Obstructive jaundice may arise in chronic appendicitis, as the result of adhesions about the gall duct; but this case is obviously not chronic appendicitis. In acute appendicitis with deep toxæmia, slight jaundice may occur; but this is not a state of deep toxæmia and the jaundice is not slight, but marked. In appendicitis with pyæmic abscess of the liver, there may be intense jaundice; but this patient lacks the other signs of pyæmia. In this case the jaundice points to trouble with the gall bladder or the gall ducts unconnected with appendicitis.

* Delivered at the Jefferson College Hospital.

This condition is not acute enteritis, although the fever, the colicky pain, and the sudden onset might suggest it. The jaundice is against this diagnosis; and so are the local rigidity, the mass, and the absence of severe vomiting.

It is obviously not intussusception; for it lacks the characteristically shaped mass which alternately becomes rigid and relaxed, and the tenesmus with the passage of bloody mucus, and presents symptoms that do not belong to intussusception.

It is not a renal, ureteral, or gastric condition.

Could it be tuberculous peritonitis? In acute tuberculous peritonitis there may be pain, tenesmus, elevated temperature, and rigidity. The pain, however, is usually slight; the tenesmus commonly trivial; and the rigidity not marked. The signs are not definitely localized, and there is a strong tendency to intestinal obstruction.

Considering everything,—the antecedent attack of typhoid, the mode of onset, the situation of the present trouble, the paroxysmal pain, the localized tenderness, the rigidity of the upper half of the rectus muscle, the mass, the jaundice, the irregularly elevated temperature, and the rapid pulse,—we are led inevitably to the diagnosis of typhoid cholecystitis with pus in the gall bladder; that is, suppurative cholecystitis. I shall have an anæsthetic administered and shall operate before you.

It was long ago known that inflammation of the gall bladder may arise during the course of typhoid fever. Both Louis and Andral were acquainted with this fact. For many years, however, it attracted comparatively little attention; and it is only during the last three or four years that professional interest in regard to it has been strongly awakened.

We now know that in most cases of typhoid fever the bacillus of Eberth enters the gall bladder. In fact, it is stated by Dr. Rolleston, of London, that in fatal cases of typhoid fever these bacilli are almost constantly present in the gall bladder. This does not, however, mean that in fatal cases of typhoid fever there is almost always cholecystitis; because the organisms may be present in quantities without there being any evidence of the existence of an inflammatory disease. There must be some factor present besides the bacilli, in order to produce this disease; or else the bacilli must be of peculiar virulence.

A great number of bacilli may be present and yet apparently do no harm whatever. They may, however, induce a catarrhal inflammation with desquamation of the epithelium; they may cause a purulent catarrh; or they may set up suppuration of the walls of the gall bladder. There may result inflammation or suppuration outside the gall bladder. In some cases pseudomembranous cholecystitis arises; in others, the gall bladder perforates from ulceration.

In cases of typhoid affections of the gall bladder, agglutinins are present in the bile or in the inflammatory exudate; and these may lead to the precipi-

tation of masses that serve as nuclei for gallstones. There have been reported by Dr. Harvey Cushing, of Baltimore, cases of posttyphoid cholecystitis in which gall stones were present, examination of these disclosing the fact that they contained typhoid bacilli. In a series of over thirty cases of cholecystitis operated upon by Professor Halsted, of Johns Hopkins University, nearly one third had had typhoid fever at varying periods before the operation. The factors present besides undue virulence of the organisms, when typhoid bacilli cause cholecystitis, may be a greatly lessened vital resistance of the system, the presence of gallstones, an antecedent inflammation of the gall bladder, an injury of the gall bladder, adhesions of the gall bladder, and particularly a blocking of the duct that permits of stagnation of the bile.

Attention has previously been called to the similarity between cholecystitis and appendicitis. It will be remembered that in appendicitis there may be catarrhal inflammation, there may be a purulent catarrh, there may be suppuration of the walls of the appendix, there may be perforation, there may be gangrene, and there may be circumappendiceal inflammation or suppuration. In both cholecystitis and appendicitis, blocking of the exit—from the gall bladder in one case, and from the appendix in the other—strongly favors inflammation, and in both very virulent microorganisms may establish an inflammation which causes the blocking.

Typhoid cholecystitis may arise during the existence of typhoid fever. The most common period for it to arise is at the end of the third week, just as the fever is beginning to decline. It is not uncommon during convalescence from the fever, and it has been pointed out by Dr. John H. Musser, of Philadelphia, that many so called relapses in typhoid are really cases of posttyphoid cholecystitis. Whenever what appears to be a relapse begins, the attending physician should carefully examine for the existence of cholecystitis.

Cholecystitis may arise months, or even years, after the occurrence of typhoid fever; and a pure culture of typhoid organisms may be obtained from the interior of the gall bladder. There are two explanations of such an occurrence. The first is that the bacilli found in the gall bladder have descended through many generations from the organisms that were present during the existence of the typhoid, and did not become active for harm to the gall bladder until some other factor had been introduced. The other explanation is that the organisms have been recently received from the intestine, the person being immune to typhoid fever, on account of his previous attack, but not being immune to inflammation of the gall bladder induced by the Eberth bacillus. In individuals that develop cholecystitis years

after an attack of typhoid fever, it is by no means uncommon to find that in the intervening period between the fever and the cholecystitis they have been sufferers from chronic indigestion and from occasional attacks of pain in the neighborhood of the pyloric end of the stomach.

A very curious fact has been called attention to of late—that is, that there have been reported cases of cholecystitis in persons that had never had typhoid fever, the typhoid bacillus having nevertheless been obtained by cultures. This matter was dwelt upon by Burley in the October number of *Medicine* for 1903. He reports a case of his own, and has collected six other cases from literature. It is, of course, conceivable that these persons may have had typhoid fever that was not diagnosed; or it may be that they were immune to the typhoid fever, although the gall bladder could still be attacked by the bacillus and made to pass into a state of inflammation.

The frequency of cholecystitis in typhoid fever is very hard to determine, because a large number of cases are probably unrecognized. Certain it is that in many cases of typhoid deep pressure over the gall bladder region occasions pain; yet, as this condition usually passes away and may not be associated with any other symptoms, it is impossible to state definitely the cause of it. Dr. John H. Musser and some other observers think that cholecystitis is much more common than is usually believed, and in many cases is unrecognized because the liver is high up and the gall bladder is under the ribs. It may not be recognized because the associated symptoms are not positive; it may not be recognized because the patient is in a condition of toxæmia and does not definitely recognize, locate, or complain of pain. Again, it may be confused with appendicitis.

The condition is rare in children of this age, and is more common in adults; but cases in children of only five years of age have been reported.

The route by which the organisms of typhoid fever reach the gall bladder has been much disputed. They may reach the bile ducts by means of the portal circulation, afterwards pass from the vessels to the bile channels, and eventually reach the gall bladder. In such a condition, cholangitis may precede or accompany the cholecystitis. It is doubtful, however, whether the normal liver will secrete the bacteria; and whereas this mode of infection may occur, it is probably not very common. It seems likely that most of the infections take place by ascending the common bile duct. If the gall bladder is adherent to the bowel wall, infection may take place in this manner. Another route of infection is through the lymphatic system, and Dr. Charles H. Mayo, of Rochester, maintains that this positively occurs. In cases of cholecystitis that have accompanied or followed typhoid fever, mixed infection with colon bacilli, staphylococci, etc., may be

found. Mixed infection with staphylococci may be followed by disappearance of the typhoid bacilli. The staphylococci attract hordes of leucocytes and the leucocytes may destroy the typhoid bacilli. There is no regularity as to the presence of leucocytosis in typhoid cholecystitis. In some cases it is present, in others it is not; it may be present in a case at one time and absent at another. In this case it is at present absent; on admission there was very slight leucocytosis.

In the patient before us, the diagnosis seems clear. He has suffered with occasional attacks of violent pain in the gall bladder region, and has persistent tenderness in the same region; there is marked rigidity of the upper half of the right rectus muscle, a mass in the right hypochondrium, a fluctuating temperature (the type being remittent), profuse sweats during the night, nausea, and very marked jaundice. Jaundice may or may not be present in these cases, and its absence would in no wise affect the diagnosis.

I purpose in this case to make an incision in the region of the gall bladder; and shall employ the incision of Dr. Bevan, of Chicago, which I have used before you a number of times. It is shaped like the *Italic* letter *f* without the cross line.

On opening the peritoneal cavity and searching for the gall bladder, I find that the colon is adherent to the under surface of the liver and is decidedly inflamed. Separating the adhesions from side to side, I am able to get my finger posterior to a mass, which is the gall bladder. I at once proceed to pack it around with iodoform gauze, inserting a piece in the foramen of Winslow; because, when I go to separate these adhesions, should there be a flow of pus, disaster might ensue if I had not protected the greater and lesser peritoneal cavities. I now separate the adhesions between the gall bladder and the colon. You see there is a burst of greenish white pus; and I exhibit to you a larger perforation in the wall of the gall bladder, the adhesions to the colon having prevented the passage of the pus into the peritoneal cavity. We shall take cultures of this pus.

I shall not remove the gall bladder, although the mucous membrane is in an advanced state of disease; because I think it not only desirable, but necessary, to drain the ducts for a number of days. I therefore scrape away the mucous membrane by the method suggested and employed by the Mayo brothers; carry the drainage tube down to the neck of the gall bladder, hold it in place with a purse string suture of the gall bladder, and surround the gall bladder with iodoform gauze, to catch any pus that may leak out by the side of the tube. I do not in this case, as in most operations requiring drainage of the gall bladder, suture the gall bladder to the abdominal fascia and the peritoneum; because the coats are so friable that the stitches would tear out.

I now close the abdominal wound, except at the point where the tube and the gauze emerge, and put on the dressings with the tube emerging between them. When the patient reaches the ward, I shall attach a long tube to this short one, in order to permit the bile to flow into a basin beneath the bed.

NOTE.—The patient recovered without an un-

favorable symptom. The culture taken from the gall bladder shows an unidentified bacillus, which is not the colon bacillus or the paracolon bacillus, and which is not identical with the typhoid bacillus or the paratyphoid bacillus. It resembles the typhoid bacillus, but possesses no agglutinative power. Further studies will be made to determine its character.

2045 WALNUT STREET.

FOOD PRESERVATIVES AND FOOD ADULTERATIONS.*

By H. W. WILEY, M. D.,
WASHINGTON, D. C.,

CHIEF OF THE BUREAU OF CHEMISTRY OF THE UNITED STATES
DEPARTMENT OF AGRICULTURE.

This, perhaps, is a hackneyed subject which you ask me to speak to you about to-night, and yet one of continued interest, not only to the physician, but also to the people themselves.

That food must be preserved is a fact recognized by every one. Only in a savage state is it necessary to eat food as it is secured, to live practically from hand to mouth; but in all civilized countries there is a laying up of stores of foods against the seasons when foods are not produced, and thus the necessity for preserving food in some way has been recognized since man emerged from the savage state.

The subject of the preservation of food by modern methods did not assume great importance until a half or a quarter of a century ago. The development of the science of chemistry placed in the hands of the manufacturer the means before unknown of preserving food, and the means of matching in manufactured foods natural tints and colors, all made possible by the development of tinctorial chemistry, on the one hand, and of synthetic chemistry, on the other hand.

We have many food preservatives which have been in use since the earliest times, the usual condimental preservatives and substances which reveal themselves to the consumers by their odor and taste, such as common salt, sugar, vinegar, and wood smoke. Their established use is well recognized and no legislation has forbidden the use of such preservatives. There is another class of preservatives, known as antiseptics; and in the quantities in which they are used they have neither taste nor odor, so that their presence is unknown to the consumer, unless stated to him.

I believe the fight against artificial coloring matters is almost won, and that the education of the public in regard to artificial colors is quite as effective in this direction as any legislation that can be enacted. The moment the people demand uncolored foods, that moment they will get them.

* Read by invitation before the Philadelphia County Medical Society.

It has been claimed that the use of colors in foods is not reprehensible so long as the colors are harmless to health. From the medical point of view I assent to that proposition. There is, however, a vice in the use of colors more insidious than the effect upon health, the vice of deception in food products. Why should a food product be made to assume a character which it does not possess naturally in respect to color? The manufacturer, who should be heard, says that the people demand that the food shall have these colors. They probably do at the present time, but they certainly did not at the beginning. The taste which now rules the public is one which has been created by the use of these coloring matters, and, therefore, the public cannot be held responsible for that taste; and, more than that, the public is certain to demand the uncolored article just as soon as they are informed in regard to the nature of these coloring matters. I refer especially to articles injurious to health rather than to that class which it is claimed have no effect of an injurious character upon the health of the consumer. I believe manufacturers agree that the use of mineral matters in foods is reprehensible. Candy manufacturers boldly proclaim this and are trying to have the use of mineral colors of any description prohibited. That is perhaps a rather sweeping condemnation, but we do know, for instance, that lead chromate and copper sulphate are not regarded by the medical profession as particularly wholesome articles of food. Copper sulphate is used because of its property of fixing in the tissues the natural green color. The color of peas and beans fades after a certain time, even though kept in the dark.

The manufacturer should have a fair inning, and he alleges that copper sulphate when added to foods enters into a chemical combination in which the copper salt becomes inert and insoluble in the digestive juices. I am not inclined to accept that as a logical argument. I have not, however, myself made any experiments looking to the determination of the effect of copper sulphate upon health and upon digestion, but am dependent upon data collected by other people. In a court of justice the accused is held to be innocent until proved guilty. Here, however, is a criminal, confessed to be guilty by everybody. Even the manufacturer will admit that copper sulphate in itself and uncombined in a food product is a harmful agent and, therefore, it should be held to be harmful until proved innocent.

As in many other cases, experts disagree in this. I am not speaking of the character of the expert. I believe that an expert has the same right to advance the interests of his client that an attorney

has, provided he does no violence to his conscience and to science. He has the right to make out the best case he can, preserving, always, his integrity. You all know that experts can take the same data and viewing them from different points, draw conclusions diametrically opposite, and do it reasonably and perhaps logically. Especially has this been true in France, where there was formerly a decision of the Committee on Hygiene prohibiting the use of copper sulphate in food products. The committee was convinced after further study that this decision was not applicable, and it was annulled. As a result we now get large quantities of food products from France containing copper in varying quantities. But the real effect of copper sulphate was not altered by this change of opinion. In considering questions of this kind, if we had the results of experiments with copper sulphate such as we have with borax we would have some additional sound and conclusive evidence. In the absence of such data, and in the presence of the conflicting opinions of experts the best thing to do is to be guided by the general principle that a substance known in itself to be injurious to health is guilty until proved innocent. All we have done in executing our food law so far is not to send the guilty party to jail, but to ask that the criminal be labelled so that all may be warned of his character. We hope some time to be able to settle this question by definite experimental evidence, but meanwhile we are content with publicity. I believe we can do more in many cases by moral suasion than by the strong arm of the law. In the almost two years of the execution of our food law we have never had a case in court and yet we have secured what we wanted. Since March 16th all food products entering this country artificially colored have had to bear a label stating the fact, though the material used for coloring need not be declared, except in the one case of the copper sulphate, which is not a coloring matter alone, but also a mordant.

I want to illustrate the position which I have occupied upon the almost universal coloring of butter. I have for many years opposed that practice, and I attended a convention some time ago in this city in which I took as it were my life in my hands upon this question. I am glad to report to this assembly that there is to-day a growing tendency among the farmers to believe that uncolored butter is better and will bring a higher price in this and other countries. The moment the dairymen understand this there will be no more difficulty about coloring butter. The farther south you go the deeper the people want the color of the butter. I don't know why a high

temperature and a desire for high color in butter go together, but it is a fact. Demand that the butter you eat shall be uncolored, and in two or three years, without trial by jury, you will get what you want. I was in a convention recently in Detroit, when one of the largest manufacturers said to me that they had joined me in my crusade against color, and that after the first of January their factory would make no more artificially colored food products. I do not believe it is a good thing for us to eat continuously even a small quantity of colors which may be regarded as harmless. They are not foods, are not, as a rule, digestible and have no relation to the chlorophyll and its derivatives which are the natural coloring matter of vegetable life. We know that there is a certain amount of foreign matter in food which is necessary to digestion, but Nature provides this in the foods. The idea which I formerly held to tenaciously, viz., that the coloring of foods by harmless matters made them more attractive and, therefore, more digestible, I no longer hold. My advice to food makers is to stop using colors as soon as they can and especially if the coloring is under suspicion of any kind.

Concerning antiseptics in relation to foods, I think the rights of the consumer are paramount. My position is that there should never be an antiseptic save those already enumerated admitted to foods, except in case of absolute necessity, unless the consumer orders it for himself. I believe anybody has a right to eat anything he pleases, but that he has no right to make another person eat the same thing. Antiseptics should not be used in food products except when ordered by the consumer, or when the foods are made for specific purposes and when they cannot be safely preserved by ordinary means until they are used and where such preservative is absolutely necessary in long journeys and in remote localities. It is far better to eat foods with antiseptics in them than to have no food at all. I am in sympathy with the campaign of education and believe that when preservatives are placed in foods the consumer should be notified; also that he ought to have the opportunity to get foods without them when he wants to. I believe many of the great food manufacturers are already excluding many of the antiseptics. At first when labelling was suggested the manufacturers said the people would not eat the correctly labelled foods. This brought them to the proposition that it was either right to deceive the consumer or to injure him. I do not believe it is right to deceive a consumer or to injure his physical health. Neither should violence be done to a man's moral health. One of the men interested in the making of foods stood

up before a committee of Congress and maintained that deception was the life of trade in foods and that the very moment you stopped deception you ruined trade.

Our experiments have convinced us that anti-septics in foods are injurious and unnecessary. Our methods of experimenting may be wrong, but they will all be published with the data and not a single fact observed has been left out. Our conclusions make the use of these substances in food products deleterious to health and they should be excluded on that ground. If I had any view at all concerning borax it was that it was the least harmful of all preservatives used in food. If it is, the others must be very injurious. We showed conclusively that borax in quantities not exceeding half a gramme a day and extending over a period of fifty or sixty days was distinctly deleterious to health, and used in large quantities it speedily put the subject out of the fight. We didn't get quite the results that our German friends did. Neither did we get those of the experts on the other side of the question employed by their clients to show that borax was harmless. The strength of our ground is that we had no client. We were not employed to do anything, except to make studies upon the effects of borax. We were not studying borax from the standpoint of the manufacturer. We were trying to enlighten the public and bring about a state of affairs radically different from that in the past. We have had a most sympathetic body of advisers in the medical profession, and I believe that through the medical profession the public will be taught the true principles of nutrition in this respect.

Sulphurous acid is found largely in foods, especially in desiccated fruits which are subjected to the fumes of burning sulphur to retain their color. It is also used to preserve wine, being produced by burning sulphur in the casks. I do not know of any way of preserving the good color of fruits during desiccation, except by fumigation with sulphurous acid. Whether that is justifiable or not I am not here to say, but that is a use which appears to be a universal one, and the same is true about the burning of the sulphur match in the barrel in wine-making; a use which has come down from antiquity. But when it is used as at the present time in an enormous excess for preserving a poor wine and putting on the market a new wine before it has ripened it is unpardonable. In this connection we are having a battle royal with our French brethren. To pay them a high compliment we adopted some time ago their standard for the use of sulphurous acid in wines, and as soon as we adopted it they objected to their own

standard and appointed a new commission who raised their standard to just double. They then appealed to us to adopt their new standard, and I suppose if we did they would make another double on us in the use of sulphurous acid.

We hope so to conduct the execution of this law that we will secure not the opposition, but the support of the importers. We are improving the character of our wines by keeping out those in which sulphurous acid is used in excess. We are improving the character of our Frankforter sausage by requiring Germany to send us such as they are willing to eat at home. Our law happily says that any food product not allowed to be sold in the country in which it is made shall not be allowed to come to the United States. On that ground we have sent back several cargoes of German sausage containing borax, and on arriving at the German frontier they are inspected and rejected, and, like the *Flying Dutchman*, they are still flying over the sea, seeking a port, a haven of rest.

I believe the application of the principle of honesty would be the best food law that could be enacted. If I were to write a food law in one sentence it would be that nothing unwholesome should be added to foods and that every food product should be marked and be exactly what it was said to be.

THE GONOCOCCUS IN THE VULVOVAGINAL REGION.*

By HERMANN J. BOLDT, M. D.,
NEW YORK.

The locality primarily attacked by gonococci is the vulvovaginal region and the urethra. In all instances of acute gonorrhœa, gonococci may be demonstrated to be present in the urethra. Even in later stages of gonorrhœa when the microorganisms have disappeared from the vulvovaginal region they may still be found in the urethra in seventy-five per cent. of the cases, if the patient retains her urine for about three hours or longer, and if the secretion is then expressed from the posterior part forward toward the meatus. Still later they may be found to have retained their abode in the peri-urethral and vulvar follicles, and in the excretory ducts of the Bartholinian glands. The prognosis is invariably good if the disease is properly treated. With very rare exceptions the progress or diffusion of the gonococci is so rapid that they invade the cervix, uterus, Fallopian tubes, and pelvic peritonæum almost simultaneously with the vulvovaginal region and urethra. Even without any treatment, gonococci disappear spontaneously from the urethra and vulvovaginal region in most instances.

* Remarks made at a meeting of the Section in Genitourinary Diseases of the New York Academy of Medicine.

If, however, proper treatment is begun early, they can be prevented from invading the more highly situated structures in fully ninety-five per cent. of the cases. The treatment should consist in the partaking of a bland diet, perfect cleanliness, and local applications. The vagina should be swabbed very thoroughly with a strong solution of one of the albumose or gelatose salts of silver. The urethra, the patient having previously urinated, should receive a similar application of a twenty-five per cent. solution. It is best applied with an intrauterine applicator syringe, made by the Kny-Scheerer Company on my suggestion. The advantage of applying this or any other medicinal agent in this manner may be obvious. The slender silver nozzle, which is four and one half inches long, is wrapped with absorbent cotton like an intrauterine applicator, the barrel of the syringe having previously been filled with the medicament. There being but one opening at the termination of the nozzle, the cotton becomes saturated from the tip backward when the fluid is ejected, and thus the solution in its full strength is brought in contact with every part of the mucous membrane. The cotton may be left in the urethra several minutes before removal. If a probe is first saturated with the solution to be used, a part of its strength is lost by its passage over the mucous membrane from before backward. The treatment should be used daily, then usually in ten days or less it will be found that the gonococci have disappeared.

ON TWO UNUSUAL CONDITIONS AFFECTING THE GASTRIC AND EPIGASTRIC REGIONS.

By W. MOSER, M. D.,

BROOKLYN,

PHYSICIAN TO THE GERMAN HOSPITAL.

CASE I.—The patient, a man about 30 years of age, consulted me in reference to a continuous distress in the gastric region. He could not describe what this distressful sensation was, but insisted that it was not painful. Status præsens: Heart normal; apex of one lung showed commencing consolidation; liver and spleen normal; stomach quite normal in position and outline; no vomiting or much gaseous eructation. Incidentally the patient stated and likewise showed that he could, as he expressed it, "push his stomach out." He did this as he said by "holding his breath." He took a deep inspiration, retracted the abdomen when presently his stomach appeared in the epigastric region like a balloon or a very large epigastric hernia.

Epigastric hernia very rarely attains such a size, and could be made to appear by acts of coughing, lifting, etc., and is, of course, an entirely different condition. The stomach, as we

are aware, admits at times of unusual mobility; but not voluntarily produced or replaceable. I refer to gastropotosis, which is a downward displacement of the stomach. What anatomical peculiarity underlies this voluntary forward displacement or dislocation I am unable to say. Athletes and physical culture exhibitors may produce through muscular action alone considerable bulging at the epigastrium. In our case possibly intraabdominal pressure and diaphragmatic action may come into play. It is possible that this abnormal mobility of the stomach may stand in relation to the distress of which he complains.

CASE II.—An Italian complained for many months of painful "knocking," as he expressed it, of his stomach and gastric region. Examination revealed clonic contractions in the epigastric region, which might be easily seen and felt.

The superficial or epigastric myoclonus did not disturb him so much as the "inside knocking," by which he meant the gastric clonic contractions. The patient complained of obstinate vomiting and diarrhoea, and was losing flesh.

The condition was probably a neurosis, or might have been secondary to serious organic lesions.

It was allied to gastrospasm (cardiospasm or pyloric spasm), in which the contractions are tonic in character, or to the "peristaltic unrest" of Kussmaul. In gastrospasm the whole stomach contracts and feels hard like a board (Hemmeter), which was not the case here.

In peristaltic unrest there was an undulatory motion, not clonic contractions, the waves varying from seven to eight in ten seconds and being continuous. This was a very distressing and obstinate condition, and difficult to subdue. I had tried bromides, valerian, etc., on a diagnosis of neurosis, with unsatisfactory results.

This condition certainly requires much further study. Epigastric myoclonus or gastroclonus *per se* is independent of clonic gastrospasm, is not associated with vomiting and diarrhoea, nor is it painful, being more like abdominal myoclonus or spasm of the abdominal muscles, which is one of my cases followed an attack of delirium tremens. It is possible that the pneumogastric or sympathetic nerve may be in some way implicated.

Bismuth and opium temporarily allay the symptoms.

In hysterical acute gastrospasm clonic or tonic contractions occur when a tube is passed or a hot or cold drink taken and not when the stomach is empty. Chronic cardiospasm produces the sensation as if some food stuck before it reached the stomach, like as occurs in stricture or carcinoma of the oesophagus. There was no difficulty in deglutition in Case II described.

In hysterical cardiospasm other symptoms of hysteria are usually present.

ATONY OF THE RECTUM AND ANAL SPHINCTERS: ITS ÆTIOLOGY, PATHOLOGY, DIAGNOSIS, AND TREATMENT.*

By WILLIAM BODENHAMER, A. M., M. D.,

NEW ROCHELLE, N. Y.

This subject is one of such general interest that the writer feels that no apology is necessary on his part for selecting it for discussion on the present occasion. Atony of the rectum is not an uncommon disease, and it is especially very interesting from the fact that it is not well understood, being almost always confounded, with what is commonly called *constipation* or *obstipation*, terms which, however, do not designate any disease whatever, neither can they be so considered or construed, for these terms simply signify the impaction or the repletion of fecal matter in the rectum, or in any other part of the intestinal canal, and are solely a cause of the disease in question, by the superdistention or dilatation of the walls of the organ, which such impaction or repletion of fecal matter induces. These terms can, therefore, represent only a cause or an effect of disease, but not the disease itself. Indeed, the writer will endeavor to show by some of the many authors he will give as references, how singularly, in this instance, they confound the cause, the effect, and the disease. But the fact must be conceded that the principal point, and the greatest difficulty in scientific practice, are to discriminate accurately between the causes and the effects of disease, for it is only by the removal of the former that we can expect to counteract effectually the operations of the latter.

Now, in order to be well understood, the writer will further say of the word *constipation*, that it is derived from the compound Latin word *constipo*, formed from *con*, together, and *stipo*, to crowd or to fill up closely; and also of the corresponding term *obstipation*, that it is derived from the Latin word *obstipo*, that is from *ob*, denoting, to obstruct, hinder, and from *stipo*, to fill up, or press closely together. It is, therefore, very evident that the abnormal stoppage or obstacle, as signified by the Latin prefix *ob*, is a foreign body in the rectum, the material or substance of which is compressed fecal matter; consequently, the obstruction or hindrance, signified by *ob*, cannot be owing to any morbid normal or organic structure pertaining to the rectum itself, causing such impediment. The true import, then, of these two words, is a mere collection of impacted, excremental matter in the rectum, the residuum of the

various processes concerned in alimentation; and that they differ so slightly in signification, that all medical lexicographers declare them to be synonymous.

ATONY, ITS DESCRIPTION AND DEFINITION.

Now, in describing or defining any disease, it is of the utmost importance to give, in the first place the etymology, signification, and application of its name. It is well known, however, that this self evident truth is singularly enough almost always ignored by both authors and lecturers on diseases of the rectum. Atony of the rectum, as its name implies (Latin, *atonia*, Greek, *arōia*, from *a*, priv, and, *trōos*, tone), consists essentially in the loss to a greater or less degree of the tone or contractile power of the muscular coat of the organ. It is not, strictly speaking, either *asthenia*, or is it *adynamia*, as some authors have named it, for it does not interfere seriously with the functions of the organ, as these terms seem to imply, no permanent or irreparable injury being done in such instances to the muscular fibres themselves by their distention; neither is it a true paralysis, such as occurs in paraplegia, but is merely a local impairment of muscular contractility. Comparatively few authors have written especially upon this affection as *rectal atony*, while numerous authorities have treated the subject under the denomination *rectal constipation*. It is evident that these names cannot be substituted the one for the other as one designates disease, the other not. Some few authors who have noticed the subject denominate it, severally, *constipation*, *distention*, *dilatation*, or *relaxation* of the rectum. But all these terms are employed in a very loose and bungling manner, and this simple circumstance alone shows that the subject has not been well studied; indeed, these terms are entirely too vague and too indefinite to denote the true nature of the malady; they merely indicate the cause or the effect, but not the real affection itself; hence, they are all misleading.

The habitual neglect to attend strictly to the calls of Nature in regularly emptying the rectal pouch is often, doubtless, a remote cause of the atony of its walls, for in such instances the consequent result of this neglect is the accumulation and impaction of the fecal matter in the cavity of the organ, which may in order be considered the approximate cause; while the superdistention or dilatation of the parietes of the organ by such repletion is the direct or immediate cause of the atony or loss of power in it; and it may be observed, too, that in such cases the protracted presence of the indurated fecal matter obtunds

* Read before the American Proctological Association at its meeting in New Orleans, La., May 6, 1903.

the organic sensibility of the rectal pouch, so that it sometimes requires something more than the mere rectal repletion itself to stimulate it to the expulsive effort.

This defect of muscular power in the rectum, the result of prolonged distention of its walls, is similar to that familiar condition which takes place in the bladder when the calls to empty it are postponed too long; in this case the organ will not respond when the effort is made to relieve it, so that catheterism must be resorted to should simpler means fail.

The distention of the rectal pouch by the impaction of fecal matter, may, on the contrary, however, be the sequel or effect instead of the direct cause of the atony; as when some other cause has previously produced it. In such a case the repletion of fecal matter is suffered to take place, because the organ is powerless to completely expel it; as, for example, atony or the loss of rectal power is often caused by the long and continued pressure of the head of the child upon the inferior portion of the rectum during a difficult and protracted labor. The writer has observed a number of such cases, and they are quite familiar to gynecologists, and are often difficult, if not impossible, to entirely relieve; he has seen some such cases, in which for months or for years after the accident the patients had not the power to expel indurated feces without resort to artificial measures. It is also well known that atony of the rectum is sometimes produced by the pressure upon the organ of ovarian tumors, uterine fibroids, uterine displacements, and the gravid uterus. It is very obvious that we can neither appreciate rightly, nor treat successfully the rectal atony in such cases without first also taking into consideration for treatment those primary and correlated affections of the genital organs themselves.

In certain conditions of the stomach and bowels there is often an excessive quantity of gas generated, which accumulates in the colon and rectum, and of itself, independent of fecal impaction, causes constant distention of these organs, and thereby produces atony of the same. Indeed, the writer must not omit mentioning here that the abuse or the too frequent use of effervescing or gaseous products, such as some mineral waters or other waters charged with gas, is also fraught with mischief by the gas producing constant undue distention of the walls of the intestinal canal, more especially in the colon and rectum, into which it so readily passes, and in which it is more or less detained, thus inducing the disease in question.

Now, as to the terms *distention*, *dilatation*, or *relaxation*, it is evident that each, like *constipation*, can only be properly used to designate the cause or the effect, as may be, instead of the atony itself. An evidence of the improper use of the term *constipation* to designate atony of the rectum, will at once appear by the manner in which it was used by the distinguished M. Bretonneau, of Tours, France, who was the preceptor of two pre-eminently great men of our profession, M. Trousseau and M. Velpeau, and who a number of years ago met with many cases in which he found "great dilatation and torpor of the rectal pouch, forming as it were, a greatly enlarged place for the lodgment of fecal matter, which sometimes accumulated in it to such an extent as to fail to be expelled by the natural efforts." This plainly described atony of the pouch of the rectum, he called *rectal constipation*, and astonished his contemporaries by the recommendation of powerful tonic and astringent injections into the rectum, remedies such as are usually employed in diarrhoea, etc., instead of the active purgatives generally used to cure constipation. But viewing the disease as atony, and not constipation so called, the tonic and astringent injections of M. Bretonneau were both highly proper and rational, as will be shown. Constipation, as it is called, has generally been attributed to torpor of the liver, and the most active concentrated cathartic remedies in the form of pills, etc., were employed to arouse the indolent organ; whereas, on the contrary, in the affection under consideration, the torpor is in the rectum itself and not in the liver, and can be relieved by much milder, safer, and more certain means. The writer himself has often witnessed great suffering from the indiscriminate and the very "infelicitous" administration of drastic purgatives in such cases.

Thus far the writer has been explicit upon several points, perhaps to prolixity, but he has found great discrepancy in the descriptions of various authors regarding this malady. Indeed, the loss of tonicity or defective muscular power in the rectum, especially in its pouch, rendering it incapable of properly expelling its contents is, to repeat, of much more frequent occurrence than is generally believed, and is doubtless often overlooked and diagnosticated as constipation of the bowels merely, and treated as such by purgatives. It is, however, an affection which is attended by much distress, inconvenience, and trouble, and is apt, unless relieved, to result in serious injury, not only to the rectum itself, but also to those organs in its immediate vicinity; indeed, whether the atony is due originally to the distention of

the rectum by impacted fecal matter, or to some other cause, it cannot continue long without also seriously affecting the muscular contraction or movement of the organ.

SOME OF THE CAUSES AND SYMPTOMS.

To enter fully into the causes, symptoms, rectal reflexes, and sequelæ which are consequent upon this pathological condition of the rectum, would far exceed the limits of this paper. A few observations, however, upon the most common causes and sequelæ of atony of the rectum, in addition to those already given, will be considered. The most common remote cause of atony is, perhaps, the habitual disregard of the calls of Nature to relieve the organ, as previously remarked. It is demonstrated by the anatomy and the physiology of the rectum and anus that Nature has designedly made provision for the accumulation as well as the retardation of the fecal matter in the rectum by furnishing this organ with a pouch or ampulla, and its extremity with a muscular mechanism in subjection to the will for the purpose of opening and closing it. This controlling and restraining power when properly and duly exercised is highly essential to our comfort and convenience, but when it is abused in order to postpone or to set aside the admonitions of Nature, so as to retain the excremental matter beyond the period when Nature calls for its expulsion, serious results, sooner or later, will inevitably ensue.

It may also be proper here to remark that not an infrequent cause of atony of the rectum is that some persons, especially females, are in the constant habit of daily using warm or hot water injections into the rectum for the purpose of evacuating this sometimes torpid organ; by continuing this pernicious practice, the rectum will soon be deprived of all normal power of evacuation by its own efforts. It must be obvious to all experienced practitioners that the continued employment of either warm or hot water enemata for the purpose of daily relieving the bowels is injurious; for, while it is true that by their first impulse they induce the peristaltic action, their reaction, however, is always followed by the muscular fibres being left more or less softened, relaxed, and deprived of their contractile power. These objections do not apply to cold water injections at the ordinary temperature; therefore, if such persons are compelled to use enemata in these instances, they should employ cold water instead of warm or hot water, by which they would more easily attain the end they have in view, and thus increase the tonicity of the muscular fibres of the rectum, and avoid the injury

of diminishing more and more every day the contractile force of those fibres; for it is known to be an established fact that the reaction of cold water leaves the muscular fibres of the rectum more vigorous, more natural, and more effectually disposed to peristaltic action; whereas the reaction of either warm or hot water leaves the muscular fibres of the organ relaxed and enervated; consequently neither warm nor hot water injections should ever be used in atony of the rectum as their tendency would be to induce the disease instead of curing it. But the abuse or the too continued use of large cold water injections may also produce atony, as they by their large quantity or bulk unduly dilate the walls of the rectum, and thus impair the power of its muscular coat. The very fashionable and frequent "flushing" of the colon, as it is called, by injecting into the bowels several gallons of water at a time, is a most pernicious practice, except in some serious disease, as many have found to their grief.

SYMPTOMS.

Some of the most prominent symptoms of atony of the rectum may be summed up as follows: There is generally experienced in confirmed cases a sensation of fullness or weight in the rectum and a frequent desire to defecate, but an evacuation, even if effected, does not altogether appease the desire, but leaves an uneasy feeling as if some fecal matter still remained, without sufficient power, however, to expel it; defecation is sometimes attended with tenesmus and forcing pains, and a discharge of mucus streaked with blood, or a discharge of fluid feces which may have passed by a fecal bolus lodged in the rectal pouch, and which may lead to an erroneous diagnosis of diarrhœa. In some of these cases the pouch of the rectum becomes dilated to an almost incredible extent, and filled with fecal matter, so that this distended viscus will sometimes be found to occupy a large space in the pelvis; while at the same time the organ makes but little or no effort to dislodge the accumulated mass; if the finger or the bougie is now introduced *per rectum* it will readily encounter the rectal bolus, and at once determine the nature of the case. The bladder, the urethra, and the other contiguous organs often participate in the irritation produced. In men the prostate gland and the bladder become affected, and in women uterine irritation and frequent micturition are the results. In such cases, whenever the rectum is completely evacuated, there is often experienced a distressed feeling of weakness in the loins, and of a sinking sensation, with a want of the usual muscular tension, until the organ again becomes moderately replenished. On

a specular examination of the empty rectal pouch in the worst cases, it will be found abnormally enlarged and presenting a smooth membranous bag, from which it would be difficult to expel indurated fecal matter by the natural efforts. In some instances, however, the pouch will be found to be partially filled with enlarged folds of loose mucous membrane, which during defecating efforts sometimes pass down into the fossa between the internal and external sphincters of the anus, blocking the narrow canal, and impeding the evacuation of the feces, and also to some extent forming an impediment to the introduction of instruments and enemas. This morbid condition of the mucous lining is doubtless the result of a neglected state of the bowels. Indeed, this affection, if neglected or mismanaged, may give rise not only to internal prolapsus recti, but also to an intussusception of the superior and undilated portion of the rectum into the dilated pouch of the inferior portion, and it may also give rise to a painful contraction or enlargement of the anal sphincters.

Atony of the rectum and colon is most commonly met with in delicate women of a lax muscular fibre, and in those whose sedentary occupations lead to a neglect of the necessary measures to insure the regularity of the functions of the organ. It is also frequently met with in delicate children.

(To be concluded.)

Adventures of Two American Officers in the East.—The War Department received a despatch on March 15th from Colonel Valery Havard, Medical Department, and Captain W. V. Judson, Corps of Engineers, military attachés with the Russian army in Manchuria, which read as follows: "Captured. Both well. Inform families. Havard, Judson." On the same day, according to the *Army and Navy Medical Journal*, for March 18, 1905, the State Department received a despatch from United States Minister Lloyd Griscom at Tokio, Japan, announcing capture by the Japanese forces near Mukden of Colonel Havard and Captain Judson, and stating that the two American officers would be sent to Tokio. Thence they will undoubtedly be ordered home to report at the War Department the results of their observations while with the Russian forces. The capture by the Japanese of these two officers leaves only one American army officer—Major Montgomery M. Macomb—with the Russian forces in the field. Major Macomb has not been heard from for two months, but it is believed at the War Department that he was with the Russian right wing during the battle of Mukden. No fear is felt by the authorities for his safety. Major General Arthur MacArthur left Tokio, Japan, on March 10th to join Marshal Oyama at Mukden. Captain John J. Pershing, United States Military Attaché at Tokio, left that city on the same day to join the army under the command of General Kuroki.

Our Subscribers' Discussions.

A SERIES OF PRIZE ESSAYS.

Questions for discussion in this department are announced at regular intervals. So far as they have been decided upon, the further questions are as follows:

XXXVII.—How do you manage the alcohol habit? (Answers due not later than April 15, 1905.)

XXXVIII.—How would you prevent disease of the vermiform appendix? (Answers due not later than May 15, 1905.)

XXXIX.—How do you treat erysipelas of the face? (Answers due not later than June 15, 1905.)

Whoever among our subscribers (with the limitations mentioned below) answers one of these questions in the manner most satisfactory to the editor and his advisers will receive a prize of \$25. No importance whatever will be attached to literary style, but the award will be based solely on the value of the substance of the answer. It is requested (but not required) that the answers be short; if practicable, no one answer to contain more than six hundred words.

Only subscribers to the *NEW YORK MEDICAL JOURNAL* and *PHILADELPHIA MEDICAL JOURNAL* (including regular and volunteer officers of the Medical Corps of the United States Army, Navy, and Marine Hospital Service, commissioned or under contract) will be entitled to compete, and all persons known to be engaged in medical journalism are disqualified. This prize will not be awarded to any one person more than once within one year. Every answer must be accompanied by the writer's full name and address, both of which we must be at liberty to publish.

The prize of \$25 for the best essay submitted in answer to question XXXVI has been awarded to Dr. Samuel Stalberg, of Philadelphia, whose article appears below.

PRIZE QUESTION NO. XXXVI.

THE DIET IN TYPHOID FEVER.

By SAMUEL STALBERG, M. D.,

PHILADELPHIA.

As soon as the diagnosis of typhoid fever, whether mild or severe, is made in an adult, he is put on the following diet: Add two ounces of boiled water to six ounces of pure raw milk, and give it to the patient, through a glass tube or a feeding cup, and either cold or warm, as is more agreeable to him, every two hours and a half of the twenty-four. Every half hour two ounces of cold boiled water is given. The water, if more agreeable to the patient, may be replaced for a time by either weak lemonade or weak tea, or the three may be alternated, water always being preferred. At least half an hour must elapse after the feeding before water is given. If the patient cannot drink two ounces of water at one time, it can be taken during the half hour. The patient rinses his mouth thoroughly after each feeding, either with a solution consisting of a teaspoonful of hydrogen peroxide in half a tumblerful of water, or of ten grains of boric acid, twenty drops of glycerin, and a few drops of lemon juice to the ounce of water. If the patient is too weak to

rinse his mouth, the nurse swabs it gently with the same solution.

On this plan my patient gets $3\frac{3}{8}$ pints of pure milk and a little more than two quarts of water during the twenty-four hours, with an allowance of four hours' uninterrupted sleep once during the same period. If the patient sleeps uninterruptedly for six hours, he is not, except in rare instances, awakened, when he gets only eight feedings, amounting to exactly three pints of milk. As a rule a patient should not be disturbed from sleep to take food. Every case of typhoid, as of any other disease, is a law unto itself, so I use the foregoing as a guide and watch my patient. If the milk agrees with him, as shown by a comparatively clean tongue, soft abdomen, and the absence of gastric symptoms, of curdy masses in the stools, and of repugnance of the patient to the milk, this diet is continued to the end of the first week of convalescence, this process dating from the day when the evening temperature first falls to normal.

If with the milk well digested, emaciation is marked, the quantity is increased to five pints, gradually, in the twenty-four hours, both by increasing the amount at each feeding and by shortening the intervals to two hours. If emaciation is still marked, an egg, either raw or soft boiled, is given with each of two or three of the daily feedings, either mixed in the milk or separately.

This brings us to those cases in which milk does not agree. When the only objection to the milk is the patient's repugnance, the latter is overcome by a little perseverance and urging, by giving teaspoonful amounts at a time, or by rendering the milk more palatable by the addition of a teaspoonful or two of coffee, etc., and we may have the patient grow accustomed to it and take it throughout the course of the disease.

When symptoms of indigestion and malassimilation of the milk present themselves, such as vomiting, eructations, diarrhœa, constipation, colicky pains, and the presence of curdy masses in the stools, the milk is either modified or replaced, in whole or in part, by other foods. The only trouble with the milk may be that too much is given—overfeeding—when it must be cut down to one half or less. In severe cases all food is stopped for a day or two.

When overfeeding is not the only cause, the milk is diluted and the precipitation of curds prevented by the addition to it of oatmeal water when there is constipation or barley water in diarrhœa. Arrowroot, gum arabic, or a teaspoonful of gelatin, which has the additional advantage of being an "albumin sparer," may be em-

ployed instead. When vomiting is present, the milk is peptonized.

If milk still disagrees, it is replaced, either wholly or in part, by the following foods: eggs, raw or soft boiled, not more than four during the twenty-four hours; broth of beef, mutton, veal, or chicken; oatmeal or rice gruel, clam soup, beef juice, and cocoa. The milk diet, or the one last described, or a mixture of the two is continued up to the end of the first week of convalescence. During the second week of convalescence milk forms the bulk of the diet, but from one to three of the milk feedings are replaced by any of the following: Milk toast or zwieback soaked in hot milk, chicken broth thickened with rice or vermicelli, raw or soft boiled eggs, junket, arrowroot and oatmeal gruel, and chicken jelly. During the third and fourth weeks more of the milk feedings are discarded, and to the list are added poached eggs, rice pudding, blanc mange, raw oysters, scraped beef sandwiches, bread and butter, baked apple, tender chicken, and finely divided broiled chop. After the fourth week a return to solid food may be made, avoiding the coarser foods, such as raw fruit, for several weeks.

When intestinal hæmorrhage occurs, food is withheld for a proper length of time, only small pieces of cracked ice being given, or teaspoonful doses of cold water, the return to food being made by giving teaspoonful doses of cold milk. In perforation all food is discontinued pending an operation.

Alcohol is not given as a food, but in cases with heart failure, delirium, etc., it is given in conjunction with other stimulants in the form of whiskey or brandy. The older and intemperate patients are those most likely to need this form of stimulation. Children are fed exclusively upon milk, which is Pasteurized or sterilized, the broths, junket, and egg albumen being allowed only when milk disagrees or is for any other reason contraindicated.

Finally, while the feedings are to be given regularly, and a minimum of nourishment is to be insisted upon, food should never be forced beyond the patient's ability to take it.

In outlining this dietary, certain principles, some well established and others theoretical, were considered. In typhoid fever we are confronted, on the one hand, by a debilitating fever which is to last some weeks, and during which the patient's strength must be maintained and conserved, and, on the other hand, by an ulcerated condition of the bowel, which must not be irritated by the passage through it of solid or rough particles of food or stretched by the gas produced

by the fermentation and decomposition of indigestible food, or perforation may occur.

Milk is the best food, because, in the first place, it is a complete food in liquid form, containing all the ingredients necessary for the maintenance of bodily nutrition. In addition, it is a good diuretic. In the second place, while it is true that milk becomes almost solid in the stomach by curdling, this is lessened by proper dilution, and hardly any residue is left after the last stages of its digestion in the first part of the small intestines. Most patients do well on an exclusive milk diet, and while the present tendency to extend the dietary in typhoid fever is not attended by so many dangers as were formerly feared, there are still good reasons for the adherence to as near a pure milk diet as possible; besides, this extension is in most cases unnecessary. The other foods mentioned do not come up to milk in either of the respects named; still, they are allowed when the use of milk is impracticable. To broth there is the additional theoretical objection that typhoid bacilli readily reproduce themselves in it, but it is allowed along with the other foods.

The liquid diet is continued for a whole week after the beginning of convalescence, for it is a fact well known by pathologists that healing of the ulcers may not be completed long after clinical recovery has taken place.

Water is important in typhoid fever, because it quenches thirst, washes out the alimentary tract, the blood, and kidneys, and supplies fluid to the, as it were, dried tissues and bodily juices. Plain water rather than carbonated is given, because the latter produces flatulence. For the same reason the latter is not used for milk dilution. Lime water is not employed for diluting the milk, because it would neutralize an already feeble gastric juice.

The care of the mouth indicated is important, as it enables the patient to take food more easily, and prevents several complications, such as stomatitis, otitis, etc.

There are cases in which, after all the typhoid symptoms have disappeared, the temperature remains elevated. This may be due to exhaustion, inanition, furunculosis, etc. In these cases the diet is to be more liberal, with proper precautions, in spite of the fever.

1331 SOUTH SIXTH STREET.

Dr. Harry M. Pierce, of St. Louis, writes:

The judicious administration of a suitable diet in typhoid fever is very often the most perplexing, as well as one of the most important questions in the treatment of this disease, for the bowels must bear the brunt of the affections. There-

fore any article which tends to increase the irritation and inflammation already present must be strictly eliminated from the diet. The food should be of the most nourishing kind, without an undue amount of residue to be passed in the stools, and it should be as varied as the patient's condition will allow. For if more than the minimum amount of waste products is to be passed, it causes a harmful increase of work by the bowels, which excites an increased blood supply and an excessive nerve stimulation, and thereby pain, excessive peristalsis, fermentation, tympanites, and perhaps hæmorrhage and perforation. The food should be varied or prepared in different ways, so that it will not become monotonous or nauseating, as is often the case. It is not necessary or advisable to limit the diet to liquids, as was formerly thought proper, except of course in dangerous and complicated cases.

Milk, in various forms, is the food *par excellence* in typhoid fever. Often, however, it is ordered in large amounts for a patient with whom it never agreed, or who disliked the taste, even when well. It will then only nauseate, or cause constipation, or be passed in the form of curds. If the taste of cow's milk cannot be tolerated, it may be given disguised as to taste or other milks substituted, such as kumyss or some proprietary milk food, or whey or buttermilk.

When it is given, it should be given in small amounts, never undiluted, but diluted with plain or mineral water, including vichy and seltzer, or peptonized, to the amount of two or three ounces every three or four hours.

Albumen is an important article of diet, and may be given at intervals in the form of egg water (made by stirring the whites of two eggs in a pint of cool water), or as egg nog.

Beef juice is best given by extracting the juice from fresh, tender beefsteak, a pinch of salt being added, or if the patient is rational and has the strength, by letting him chew small pieces of beefsteak, the nurse standing by to see that none is swallowed.

Barley water and rice water, well strained, to which a pinch of salt may be added, forms an important addition and relieves the monotony of a milk diet. The patient should be given plenty of cool (not ice cold) water or lemonade at frequent intervals. Weak tea, coffee, and cocoa form agreeable beverages and act as gentle stimulants.

Alcohol in small amounts should be given as a food in the form of egg nog or sherry and other light wines. Sweet wines, such as port wine, also ale, porter, and beer, are contraindicated.

Unless the case is complicated or of a danger-

ous character, it is best to give, at intervals (after ten or fourteen days), various semisolids, as follows:

Eggs, soft boiled, poached, or raw and well beaten.

Gelatins, plain custards, ice cream (plain), and other delicacies, such as blanc mange and soft puddings without raisins.

Soups, chicken, beef, oyster, rice, and barley, well strained and slightly seasoned; or they may be thickened with rice, barley, or a few plain crackers.

No solid food should be given for a week or ten days after all fever has left. This rule will prevent many a complication and relapse. Care should then be taken to add only the most digestible articles, and they should be given only at intervals and in small amounts. White meat of chicken or turkey, squab, tender beefsteaks, lamb chops, white fish, strictly fresh, and white mashed potatoes may be allowed, also tender and digestible vegetables, preferably stewed, and perhaps a small amount of stewed fresh fruits. Pork, in any form, veal, coarse and canned vegetables and fruits, fried articles, hot bread, pastry, gravies, and all rich and highly seasoned articles are strictly contraindicated.

If, after giving solid or semisolid food, distressing symptoms appear, such as pain, diarrhœa, tympanites, or even a slight rise in temperature, all solid and semisolid food should be withdrawn and the patient kept on a liquid diet until all these symptoms have disappeared. It is a good plan to allow no food for at least twenty-four hours.

The above described diet is prescribed for an uncomplicated and typical case of typhoid fever. When complications arise, the physician must use his own judgment in regard to what foods to allow.

When rectal feeding must be resorted to, it is usual to give four ounces at each feeding, composed of milk, without cream, to which an egg, well beaten, and three or four teaspoonfuls of whiskey or brandy have been added. This amount is given about every six hours. Much more than this amount is not apt to be retained or assimilated.

(To be concluded.)

Hyperpepsia is combated successfully, according to Soupault, cited in *Revue française de médecine et de chirurgie*, for September 19, 1904, by the following powder:

℞ Sodium phosphate.....5 grammes (75 grains);
Sodium bicarbonate.....4 grammes (1 drachm);
Sodium sulphate.....3 grammes (45 grains).

M. Take one such powder in a glass of alkaline water, daily, before breakfast.

Correspondence.

LETTER FROM PARIS.

The Shortcomings of the Hôpital Laennec.—Dr. Doyen and the Micrococcus Neoformans.—Paris as a Dwelling Place for Consumptives.—The Society for the Prevention of Consumption.—Sailing Vessels as Propagators of Yellow Fever.—Tuberculous Cows.—The Brains of Great Men.—A Gift by Madame Zola.—American Practitioners.—Rivious Students.

PARIS, March 26, 1905.

The newspaper called *Le Matin* may, of course, have other reasons for existence, but a great amount of its energy is devoted to keeping the Parisian hospitals from dropping into a slough of atrocious inefficacy. This week it is the Hôpital Laennec that is being considered, and the cause of the drubbing it is receiving lies in the shameful neglect of applicants for treatment. Like most hospitals here, it is immensely picturesque; like most also, it affords clinical material to students from the four corners of the earth; but, also like most, its sanitary condition is more suitable to China than to civilized France. The constant scourgings administered by the daily press seem to affect the hospitals in no way whatsoever, except, possibly, to keep them from becoming unthinkable worse. Of neglect, several examples are given where patients upon admission have been left for twenty-four hours without food. Of course I do not know the true reason for this, but it is quite within the limits of credibility that the money thus saved for the hospital goes into the hands of some brutal and heartless underling. Such things are done, and are quite in consonance with the strange French character.

Dr. Doyen—and the question about him is never *Is he doing any thing?* but always *What is he doing?*—is now before the public as a victim of persecution. Verily some bright man with time for trifles should put Doyen into a libretto, for in this Latin country he has all the importance of a pirate in opera bouffe. Some time ago, during the last Surgical Congress, Dr. Doyen obtained the appointment by the Surgical Society of a committee of its members for the purpose of following the methods which obtain in his clinic in the rue Piccini. Professor Metchnikoff, who was on the committee, made a report from the bacteriological point of view, and in this report, which was read before the society, Professor Metchnikoff recognized the existence of the *Micrococcus neoformans*, which Dr. Doyen discovered.

Since then Doyen has continued his researches.

Notably, it seems that by a number of demonstrable facts he has established the possibility of the transmission of cancer as a result of inoculation with the *Micrococcus neoformans*. With the object of making his discovery known to the scientific world, he addressed to the Academy of Medicine a request that he be permitted to deliver a lecture on the subject, accompanied by an exposition of his micrographic work. After such approval as Metchnikoff had given to his work, it seemed only natural that the Academy should accede to his request. But a contrary result was produced, for the Academy returned to him his photographs and his other preparations, and denied his request, on the ground that it could not nominate a commission to do over again such work as had already been done by the commission of the Surgical Society. The papers here have come to his aid; they have a mysterious trick of coming to his aid; but he did not need it. The day after, or very soon after, he read before the Anatomical Society a paper—the paper—on the Serum Diagnosis of Cancer. He also invited the society to study his microscopical preparations in the laboratory of Dr. Cornil. Moreover, as Harduin (a prominent French journalist) gravely announces, “very soon the great scientific public of Paris will be called to listen while Dr. Doyen himself shows forth the very important results of his researches upon cancer.” This whole matter of the Doyen controversy has proved to be a very excellent advertisement for Dr. Doyen himself, but so artistically handled withal that there is nothing toward which the most prudish of American doctors can point the finger of scorn.

The official placards of the French government are white. No private individual may put up a white poster, and fully one third of the official posters seem to be designed to educate the people upon consumption. Paris is one of the worst cities in the world for a consumptive to live in, if we are to credit the mortality tables. I find few writers, however, who give proper importance to the food of the Parisians and to the conditions in which they exist. The typical Parisian cares not a straw what he eats, so long as he may soak himself with strong drink, and I am constantly marveling at the meagre portions that content the restaurant frequenters. This, also the small rooms; the lack of water, the uncleanly habits, the vile sanitary arrangements, and the use of charcoal fires are things that should be eliminated, and if they were eliminated, I have no doubt that Paris would prove to be a desirable city for the consumptive to live in, or, at least, no worse than Washington or Baltimore, which have

approximately the same climate with a much smaller mortality from tuberculosis.

On March 12th M. Etienne, Minister of the Interior, presided over the annual general assembly of the Society for the Prevention of Consumption. Dr. F. Plicque received the five hundred franc prize of the assembly for his educational brochure.

At the Academy of Medicine Professor Chante-messe has brought forward facts to show that sailing vessels are more likely to be agents of the propagation of yellow fever than steam vessels, and M. Moussu, a professor in the Veterinary School of Alfort, has asserted, not only that the milk of tuberculous cows should not be used, but that no cow ever so slightly affected should be tolerated on a dairy farm.

Professor Poirier recently delivered an interesting lecture at the Sorbonne upon the brains of great men. Beyond explaining that modern science did not permit us to draw any conclusions as to the intellectual capacity of the individuals by an examination of the brain alone, nothing new was developed. Of cerebral localization, he spoke at length.

Madame Zola, the widow of the late writer, has offered the property at Medan to the public charities of Paris, the buildings thereon to be devoted to hospital purposes.

Along the boulevards, and on the avenue de l'opéra one sees everywhere the sign “American Dentist,” and Paris seems to be the city for an American dentist if the prices that Parisians are willing to pay for American dentistry are any criterion. The American surgeon, too, is highly esteemed, but it is the American quack who takes the palm. In all the Vespaciennes his placards are posted, with the Stars and Stripes to support his assertion. The skin grafters are also beginning to invade the Paris field, and glaring advertisements are cropping up on every hand.

Here, whenever the students have nothing else to do they start a riot. Anything will serve as a pretext, even the meteorological condition. Whether it is to the credit or discredit of the medical students I shall not say, but they excel all other students in this sort of deviltry. Before I began to write this note in the Café Vachette—all writing here is done in cafés—I noted outside the window, on the corner of the rue des Ecoles and the Boul' Mich', about fifty medical students. They were demonstrating against Professor Gariel. “Conspuez Gariel! A bas Gariel!” Other students joined them, and now the whole quarter is in a riot, with two hundred policemen endeavoring to keep the peace.

Therapeutical Notes.

NOTES ON THE NEWER MATERIA MEDICA.

(Continued from page 651.)

Antitetanic dusting powder is a mixture of equal parts of chloretone and dried antitetanic serum, which is used as a local application as a prophylactic against tetanus.

Aristol oil is a sterilized 10 per cent. solution of aristol in sesame oil, which forms a clear, reddish brown liquid that never decomposes or becomes rancid. It is recommended in the treatment of different diseases of the eye.

Cupridol is the name used to designate a 1 per cent. solution of mercuric iodide in oil, which is used hypodermically in the treatment of syphilis.

Decemliquor is represented to be a stable decuple iron manganate solution, 1 part of which, upon dilution with 1 part of 96 per cent. alcohol and 8 parts of water, yields a simple solution ready for use.

Digalen, the so called soluble digitoxin of Cloëtta, is now offered in aqueous solution containing 25 per cent. of glycerin and 3 Mg. of amorphous digitoxin, and put up in original vials of a capacity of 15 Cc.

Digitalysatum Bürger is a standardized preparation of digitalis, each gramme of which contains 0.7 Mg. of crude digitalin, corresponding to 1 Gm. of the fresh and 0.2 Gm. of the dried leaf. It is asserted to be made from selected, freshly sun dried digitalis leaf. The dose is 1 Gm.

Digitoxin, soluble, is a white, amorphous body which is described by the discoverer (Cloëtta) as a substance chemically identical with crystalline digitoxin. (See Digalen.)

Duran is a combination of calcium carbonate and phosphate with egg albumen, in the form of a white powder; it is also put up in chocolate tablet form. It is said to be useful in children's diseases, particularly rickets and similar ailments.

Durana is the name given by a German firm to a rubber plaster, mull and cambric plaster, prepared according to the process of Unna.

Dysentrol is referred to as an extract of bidam, of German origin, the nature of which is unknown to us. It is put up as a fluid extract and in tablet form, and is recommended in the treatment of dysentery in doses of three tablets daily or a teaspoonful of the fluid extract thrice daily.

Elchina is referred to as a fortified cinchona elixir containing 0.32 per cent. quinine, 2 per cent. sodium glycerophosphate and 1 per cent. tincture of nux vomica. Mixed with wine and in some cases with the addition of 3 per cent. of hydrochloric acid it is considered useful in gastric affections and weakened conditions of the system.

Emulgates are dry, light, and rather pleasant tasting powders, which may be administered pure or mixed with sugar in capsule or tablet form. The powders are prepared by a special process from equal parts of oils and lecithalbumin. A number of these so called emulgates have been put on the market under the names of castor oil

emulgate, cod liver oil emulgate, iodipin emulgate, bromipin emulgate, creostal emulgate, sandal oil emulgate, copaiba emulgate, male-fern emulgate, etc.

Enesol is a mercury salicylarsinite, obtained by the action of methylarsinic acid on basic mercuric salicylate. It is a white, amorphous powder, soluble in water to the extent of 1 in 25. It is said to form a less irritating and less toxic substance than its constituents separately.

Enterin is the name under which a hexamethyl-entetramine proteid has been introduced. It is used as an antipyretic and astringent in doses of 0.75 gm.

Erosan is one of the new guaiacol elixirs put up by a Swiss firm. It is said to consist of potassium sulphoguaiacolate, gm. 10; water, gm. 30; syrup, gm. 105; fluid extract of orange peel, gm. 5; and ethyl morphine hydrochloride (dionine), gm. 0.3. This may be identical with erasin, previously reported, as it is a common occurrence for names to become altered in the printing.

Ether salicylate has been introduced as a substitute for mesotan. Mixed with an equal volume of castor and olive oils it is used in this way as an external application in the treatment of rheumatism.

Eucaine lactate appears in form of a white powder, with a melting point of 155 degrees C. It is easily soluble in water, forming a solution of faint alkaline reaction; 119 gm. of eucaine lactate contains the same amount of eucaine base as 100 gm. of eucaine hydrochloride. It is said to be very effective as a local anæsthetic, and is preferred in eye, ear, nose, and throat operations, being prepared in solutions of different strengths according to the site of operation.

Eusoma, a word compounded of the Greek prefix *eu*, meaning well, good, etc., and the suffix *soma*, meaning the body, is applied to a liquid compound of *Echinacea angustifolia*, *Thuja Occidentalis* and *Baptisia tinctoria*, which has been used successfully as an antiseptic dressing in the treatment of wounds and skin diseases.

Fatigue antitoxine is said to be obtained by injecting into horses a specific toxine obtained from muscles of animals which have been worked to death. W. Weichardt's own account of his discovery, as translated from the *Deutsche medizinische Wochenschrift*, is as follows: "The author pulled guinea pigs back and forth over rough ground until they were very tired and there came a sinking of the bodily temperature. Under careful antiseptic precautions I obtained some muscular plasma, which, as compared with the normal flesh, tasted bitter, and was reddish in color. Animals into which it was injected in any quantity died promptly. I secured some of the dialysable matter of the residue, which contained a toxine, which in a few weeks became absolutely dry, and at low temperature remained active. Injected into animals it produced an antitoxine. Consumption (*verfütterung*) of this antitoxine produces a species of immunity against weariness. Contrary to the toxine, the antitoxine is dialysable, and therefore easy to obtain."

NEW YORK MEDICAL JOURNAL

NEW YORK, SATURDAY, APRIL 8, 1905.

THIS JOURNAL'S FORTY YEARS OF PUBLICATION.

The first number of the *New York Medical Journal*—it was started as a monthly—was dated April, 1865, the month that witnessed the virtual termination of the great civil war and the assassination of the beloved President of the United States, Abraham Lincoln. The times were troublous, and to found a new medical journal was venture-some. Had the venture been assumed by any ordinary man, failure would probably have followed; but it was taken by so strong a man as Dr. William A. Hammond, a man who, though certain martinets had succeeded in temporarily humiliating him, stood honored by the medical profession of the whole world. Dr. Hammond launched the journal upon a successful and creditable career, and its further conduct, up to the time when, with the beginning of the year 1880, the present editor assumed control, was under the editorship successively of Dr. Edward S. Dunster, Dr. William T. Lusk, and Dr. James B. Hunter—all well known men.

When the present editor entered upon his duties, the time for changing the journal from a monthly to a weekly seemed to him to have arrived, but it was not until three years later that the publishers thought themselves justified in making the change. The first actual issue of it

as a weekly was dated January 6, 1883. In size of page and in general typographical appearance it was then exactly what it is now, but the pages of reading matter were only twenty-eight in number. Successive amplification has brought us to the fifty-two page numbers of the present day. In 1890, when the journal became the property of its present publishers, it had only a short time before been expanded to thirty-six pages—a gain of eight over the original number. Since that time it has gained sixteen. During less than five years of its present ownership, therefore, it has been enlarged twice as much as during the seventeen preceding years of its publication as a weekly. Its circulation has steadily increased, until now it is believed to have the largest of any weekly medical journal printed in the English language (and probably in any other language), if we exclude such circulation as is mainly provided for by membership in some organization. It was powerfully reenforced in 1903 by the consolidation with it of the *Philadelphia Medical Journal*, whose best features the consolidated journal has since continued.

Though the position of this journal has always been conservative, avoiding the sensational and seeking only to give its readers the greatest practicable amount of useful matter, it can point to certain occasions when it took a stand calling for some courage—notably its early warning against too implicit a trust in the supposed curative powers of Koch's tuberculin and its defense of the German surgeons in the memorable case of "Frederick the Noble." Such is the present activity of medical journalism that it is not easy to add to any individual journal a feature that is at the same time novel and valuable. Perhaps our most noteworthy achievements in that direction are to be seen in our department of Subscribers' Discussions and in that of Issues and Events of the Day.

While we do not believe in cackling like a hen when she has laid an egg, it has seemed proper to remark in this general way upon the completion of our forty years of publication. We do not in the least doubt that in the future we shall meet with that cordial appreciation and cooperation of our subscribers that we have to thank for our

successful career thus far, and we look forward therefore to still further advances in usefulness to the profession of medicine.

LESIONS OF THE BONE MARROW IN TYPHOID FEVER.

It is gratifyingly evident that the *Bulletins* issued by the Ayer Clinical Laboratory of the Pennsylvania Hospital are worthy to be ranked with the *Journal of Experimental Medicine*, the *Journal of Medical Research*, and other publications of the first order that this country has within the last few years been contributing to the solid medical literature of the world. The second number of the *Bulletin*, now before us, opens with an article by the director of the laboratory, Dr. Warfield T. Longcope, entitled *A Study of the Bone Marrow in Typhoid Fever and Other Acute Infections*. The field of investigation gone over by the author is not one that had before been entirely overlooked, but it must be conceded, we think, that his work has covered it much more thoroughly than any one person's previous researches and perhaps more systematically than those of all other preceding investigators. The interest of the subject and the light that its study may shed on the morbid processes set up by some of the infections are readily apparent. In addition to typhoid fever, the diseases studied by Dr. Longcope with regard to changes in the marrow were pneumonia, peritonitis, chronic nephritis, and tuberculous disease, but to a certain extent acute cerebrospinal meningitis and puerperal septicæmia also were investigated.

In twenty-six cases of typhoid fever Dr. Longcope found certain definite and constant histological lesions closely resembling those of the mesenteric glands and the lymphoid follicles of the intestine and spleen. They were characterized by the presence of many lymphoid cells, large phagocytes, and foci of necrosis, with more or less hyperplasia of the blood-forming cells. In many cases of intestinal perforation and general peritonitis there were, besides the disseminated foci of necrosis, diffuse degenerative changes in blood-forming cells, accompanied with marked œdema and congestion of the tissues. Differential counts of the bone marrow cells in ten cases showed a decided relative increase of the lymphoid cells

over the granular myelocytes. The author thinks it possible that the lesions of the marrow are in some way nearly related to the hypoleucocytosis characteristic of the disease, and perhaps the cause of it.

THE QUICK ACTION THERMOMETER.

There seems to us to be food for reflection in one of the sections of a pamphlet entitled *The Testing of Clinical Thermometers* recently issued by the Bureau of Standards of the Department of Commerce and Labor. The half minute thermometer appears to have been produced in compliance with an unreasonable call on the part of the profession, and possibly those who have joined in the demand have to some extent defeated their own purpose. There are clinical thermometers, we are told in the pamphlet, that, "when properly used," require from less than half a minute to two minutes to indicate the temperature within the mouth, and in a water bath, it is said, these same thermometers will generally "take up" the temperature of the bath in five seconds or less.

The structural requirements of such a thermometer make it fragile in the extreme and its index difficult to replace. It is in this difficulty of shaking the index down below the normal mark that there probably resides the chief stumbling block in the way of rapid thermometry, for a thermometric observation involves such shaking down as well as the retention of the bulb in place for a specified time. In addition, for some persons there is required the devotion of an appreciable space of time to such management of the magnifying front as to make it practicable to read the scale. When these things are taken into account, we doubt if the half minute thermometer really saves times to the busy practitioner. We may admit, of course, that it abbreviates the patient's annoyance, though that curtailment is held to be dependent on the patient's keeping the bulb "under and in good contact with the tongue," care being taken "not to press the thermometer against the tongue hard enough to impede circulation," and "not to inhale air through the mouth." We do not think it advisable to place a thermometer under the tongue, for in that situation it is a torment to a sick man, who, if he is at

all inclined to doze, is apt to crush it between his teeth. The best place, it seems to us, is between the molar teeth and the cheek, and we doubt if the difference in temperature between that space and the one under the tongue is sufficient to vitiate an observation. Attempts at quick thermometry, we believe, have been overdone.

THE REVIEWING SHAM.

Few things of human interest contain so much humbug as the review departments of various publications. The medical journal, which should be freer from adverse criticism in this regard than the secular periodicals and newspapers, is peculiarly open to impeachment. The abuses of reviewing are by no means confined, however, to the journals. Publishers are wont to send for review works of such trifling importance that mere mention of their titles, publishers, and prices is more than compensation for the expense incidental to the publication and postage of the work. In many instances, however, the publisher is at considerable expense in the presentation of review copies of works of considerable importance. It is not my purpose to discuss here the relations of the book publisher and journal, save to say that a better understanding between them along common sense lines is decidedly in order.

What I have to say bears solely upon the interests of valuable literary productions and the educational features of reviews. Oftentimes the reviewer is expected to review such books as are allotted to him and receive no other compensation for his work than the book itself. This is perhaps most frequently the case with medical book reviewers. The reviewer is more often than not an individual whose professional and literary experience by no means qualifies him for the work. The spectacle of the tyro in medicine reviewing a comprehensive scientific treatise by an author of many years' experience and profound learning is more amusing than edifying. The airy manner in which some ignorant reviewers will wave aside works comprising the best effort of the best years of the author's life is by no means encouraging to honest literary and scientific endeavor. The larger percentage of books of which alleged reviews are published are, as a recent

writer in the London *Author* pertinently remarks, "either never read or merely skimmed through, quoted from, condemned or praised at the whim of the reviewer."

Some reviewers entertain the fallacious idea that the author and publisher are highly entertained and fully compensated for sending a book for review by a flattering eulogy of the work. Other reviewers fondly imagine that to condemn a really valuable work *in toto* is the strongest possible evidence of the wisdom, scientific acumen, and literary discernment of the writer of the review. Both are decidedly in error. It would require literary and scientific ability of a very high order to write a book of any pretensions which would be wholly good or wholly bad. The wise author or publisher is he who weighs reviews which are merely eulogistic and those which are sweepingly condemnatory in the same balance, and entertains only contempt for them. A review which shows plainly that the writer of it has merely skimmed the book through or read only the title page is accepted by the initiated as evidence of the incapacity of the reviewer. When he is so impertinent as to utterly condemn without argument a work which has required years of preparation and the best thought of its author, he merely decorates himself, to use a well worn metaphor, with a pair of long, mouse-colored ears.

Many of the reviews which are published in medical journals are mere reiterations. A journal of more or less prominence having published a review, the lesser lights of journalism simply republish it in many instances. So lazy are the reviewers employed by many medical journals that in order to get a review which will show the scope and character of a book it is necessary for the publisher to send with the work a printed or typewritten synopsis of its contents. This plan alone will in many instances prevent a complete waste of the volume and the postage required to transmit it to the journal.

In these days of multitudinous literary productions, the review department of a periodical should be considered one of its main features, and not a matter of secondary importance. One would think, to read the reviews and notices in some of

our prominent medical journals, that the editors begrudged any more space than was necessary to stimulate publishers to send them volumes to be sold for the personal benefit of the editor or to be added to his own private library.

The review department of medical journals should be comprehensive, up to date, and conducted by men of sufficient learning and literary discernment to make their reviews valuable. In general, much more space should be accorded the review department than is the usual custom. Reviews of new medical works are of much more importance to the subscribers of the journal than My Last One Hundred Cases of Catheterization of the Iter a Tertio ad Quartum Ventriculum, by Professor A. Packinghouse Carver, of the Hospital of the Little Sisters of the Rich.

Last, but not least, erudite and critical reviews would serve as a stimulus and educator for the author who conscientiously desires to do good work. To maintain a proper and authoritative standard for such reviews, the plan recently adopted by the *New York Medical Journal* and *Philadelphia Medical Journal*, that of purchasing for review works which are of real importance, would seem wisest.

G. FRANK LYDSTON.

DR. CHARLES A. L. REED AND ISTHMIAN SANITATION.

Dr. Reed's strictures on the policy pursued by the late Isthmian Commission of cramping the work of Colonel Gorgas and the other sanitary officers on the Isthmus of Panama gives promise of resulting in a very wholesome change. Some people have fancied that their publication by Dr. Reed was indiscreet, but in our opinion it was not only justified, but actually called for by the condition of things.

THE SO CALLED GLOBUS HYSTERICUS.

The hysterical nature of the subjective sensation known as globus hystericus is put in very serious doubt by Dr. Max Buch (*St. Petersburger medicinische Wochenschrift*, 1905, No. 4; *Berliner klinische Wochenschrift*, March 6th), who reports twenty cases in which it was associated with decided hyperalgesia of the cervical and lumbar sympathetics. In half of them the sensation could be evoked by pressure on the lumbar sympathetic. Not one of his patients was hysterical, but most of them were chlorotic. Six of them were men, and they all had neurasthenia.

THE DIFFICULTIES OF SANITATION IN RUSSIA.

The plight of the medical profession in Russia will be brought home to physicians of this country when they read that the recent medical congress in Moscow, in spite of heavily penalized bureaucratic orders to the contrary, was obliged to discuss political questions in connection with measures designed to prevent a plague of cholera. A resolution was passed declaring that an improvement in the economic conditions of the people was necessary as a basis for the preservation of health, and that for the future prevention of epidemics it was imperative to have radical changes in the tax laws, to grant an increase in the quantity of land allotted to the peasants, to satisfy the demands of the industrial classes, and to grant all the concessions necessary to completely tranquilize the ignorant population, among whom otherwise it would be impossible to execute sanitary measures. Even the lives of doctors, the resolutions said, would otherwise be in danger.

AN UNUSUAL CASE OF MENINGITIS.

On Monday morning a young woman was picked up in the street in New York in an advanced stage of alcoholic intoxication. Upon her recovery from this attack she was found to be suffering from cerebrospinal meningitis and is, we believe, still under treatment for the latter. This case is interesting in leading to speculation as to what effect alcoholic saturation of the system may have on the course and prognosis of meningitis.

Obituary.

WILLIAM BODENHAMER, M. D., LL. D.,
OF NEW ROCHELLE, N. Y.

In the decease of this aged physician—he was in his ninety-seventh year—the profession has lost a man who was still of great power, though it is several years since he retired from practice. Dr. Bodenhamer was for many years a specialist in rectal diseases in New York, and his treatise on those affections, published many years ago, is a work still frequently consulted. In recent years it has been our privilege to publish several of his articles, all showing his erudition and distinguished for precision of statement; and the correspondence involved has impressed us with his modesty and amiability.

The Osler Dinner.—Invitations to subscribe to this dinner, to be given at the Waldorf-Astoria, New York, on Tuesday evening, May 2nd, may be obtained by applying to the chairman, Dr. James Tyson, 1506 Spruce Street, Philadelphia, up to April 20th.

News Items

Society Meetings for the Coming Week:

MONDAY, April 10th.—New York Academy of Medicine (Section in General Surgery); New York Academy of Sciences (Section in Chemistry and Technology); Medical Association of the Greater City of New York; Society of Medical Jurisprudence, New York; New York Medicohistorical Society (private); New York Ophthalmological Society (private); Gynecological Society of Boston; Corning, N. Y., Medical Association; Burlington, Vt., Medical and Surgical Club; Norwalk, Conn., Medical Society (private).

TUESDAY, April 11th.—New York Academy of Medicine (Section in Genitourinary Surgery); New York Medical Union (private); New York Obstetrical Society (private); Buffalo Academy of Medicine (Section in Medicine); Kings County, N. Y., Medical Association; Rome, N. Y., Medical Society; Medical Society of the County of Rensselaer, N. Y.; Newark, N. J., Medical Association (private); Trenton, N. J., Medical Association; Clinical Society of the Elizabeth, N. J., General Hospital and Dispensary; Northwestern Medical Society of Philadelphia; Practitioners' Club, Richmond, Ky.; Richmond, Va., Academy of Medicine and Surgery.

WEDNESDAY, April 12th.—Medical Society of the Borough of the Bronx, New York; New York Pathological Society; New York Surgical Society; American Microscopical Society of the City of New York; Society of the Alumni of the City (Charity) Hospital, New York; Society for Medical Progress, New York; Pittsfield, Mass., Medical Association (private); Philadelphia County Medical Society; Lenox Medical and Surgical Society (private).

THURSDAY, April 13th.—New York Academy of Medicine (Sections in Pediatrics and Otolary); Society of Medical Jurisprudence and State Medicine, New York; Brooklyn Pathological Society; Medical Society of the County of Cayuga, N. Y.; South Boston, Mass., Medical Club (private); Pathological Society of Philadelphia; Church Hill Medical Society of Richmond, Va.

FRIDAY, April 14th.—New York Academy of Medicine (Section in Neurology); Yorkville Medical Association, New York (private); Brooklyn Dermatological and Genitourinary Society (private); German Medical Society of Brooklyn; Medical Society of the Town of Saugerties, N. Y.

NEW YORK.

Infectious Diseases in New York:

We are indebted to the Bureau of Records of the Health Department for the following statement of new cases and deaths reported for the two weeks ending April 1, 1905:

	April 1.		March 25.	
	Cases.	Deaths.	Cases.	Deaths.
Measles	470	21	379	9
Diphtheria and croup.....	317	31	294	38
Scarlet fever.....	224	20	258	13
Smallpox	1
Chickenpox	149	..	180	..
Tuberculosis	413	172	576	198
Typhoid fever.....	45	6	19	6
Cerebrospinal meningitis.....	189	131	167	85
	1,808	381	1,873	349

Society of Sanitary and Moral Prophylaxis.—

A meeting of this society will be held at the Academy of Medicine on Friday, April 14th, at 8.30 p. m. The business before the meeting will be adoption of constitution and by laws; papers on: Education in Sexual Hygiene, by Dr. John H. Elliott, of the Hudson Guild; The Sexual Necessity, by Dr. Edward L. Keyes; Attitude of the Church Toward Sexual Hygiene, by Reverend Henry A. Brann, rector of St. Agnes's Roman Catholic Church; Ignorance, Perversion, and Degeneracy, by Mr. Frank Moss, of the Society for the Prevention of Vice; Education Within the Medical Profession, by Dr. Prince A. Morrow.

The papers will be discussed by prominent members of the laity and of the medical profession. Stephen Smith, M. D., chairman; Edward L. Keyes, Jr., M. D., secretary *pro tem*.

The Medical Association of the Greater City of New York.—A stated meeting of this association will be held in Hosack Hall, New York Academy of Medicine, on Monday, April 10, 1905, at 8.30 p. m. Order of exercises: Immunity and Infection; Introductory Lecture on Immunity, by Dr. Edward K. Dunham; Phagocytosis in Its Relation to Immunity, by Dr. Eugene L. Opie; Therapeutic Value of Antitoxic Sera, by Dr. H. T. Marshall; Therapeutic Value of Bactericidal Sera, by Dr. H. D. Pease; Diphtheria Antitoxine in Cerebrospinal Meningitis, by Dr. Arthur J. Wolff; Limitations of Serum Therapy, by Dr. Henry W. Berg; discussion by Dr. William H. Park, Dr. James Ewing, Dr. Frank Grauer, Dr. James C. Ayer, and Dr. Edward Waitzfelder. J. Lee Morrill, M. D., treasurer; P. Brynberg Porter, M. D., recording secretary, 150 West Eighty-fourth Street.

New York Hospital Commission.—John E. Parsons, chairman of the committee of twelve recently appointed to consider propositions for the benefit of New York city hospitals, was empowered by his committee at its first meeting on April 3rd at R. Fulton Cutting's office, 32 Nassau Street, to select four subcommittees which are to hold frequent meetings and report to the general hospital committee. These subcommittees are to deal, respectively, with hospital support, hospital cooperation, hospital economics, and hospital accounting. The committee of twelve, which was appointed by Mr. Cutting, president of the Association for Improving the Condition of the Poor, consists of Frederick Sturges, Dr. John A. Wyeth, Dr. John Winters Brannan, Isaac Wallach, Hoffman Miller, Seth Low, Thomas Mulry, representing the Roman Catholic hospitals; T. O. Callender, representing the Brooklyn hospitals; Frank Tucker, vice-president of the Provident Loan Society; Frederick A. Cleveland, chairman of the subcommittee on accounting of the Mayor's finance committee of fifteen, and Leonard E. Opydyck, secretary of the New York Association for Improving the Condition of the Poor.

Academy of Medicine.—The Section in Pediatrics will meet on Thursday, April 13th, at 8.15 p. m. Order: Presentation of patients: A Case of Congenital Defect of Some of the Shoulder Muscles, by Dr. Charles Herrman; A Case of Hæmophilia in a Girl of Eleven Years, by Dr. Matthias Nicoll, Jr.; report of cases: A Case of Intrauterine Amputations, by Dr. William L. Stowell; paper: The Fat Question in Its Relation to the Production of Infantile Marasmus, by Dr. Heinrich Stern; paper: Important Points in the Diagnosis of Sporadic Cretinism, Mongolism, Achondroplasia, and Rachitis, by Dr. Charles Herrman. Discussion by Dr. Louis Fischer, Dr. Louis C. Ager, and others. L. E. La Fetra, M. D., chairman; John Howland, M. D., secretary, 49 East Fifty-third Street.

The Section in Otolary will meet on Thursday,

April 13th, at 8.15 p. m. Order: A Case of Mastoiditis, Complicated by Gangrene of the Lung, Endocarditis, and Pericarditis, without Apparent Involvement of the Lateral Sinus, by Dr. S. McCullagh; (a) A Case of Exploratory Cerebrotomy, (b) Exhibition of a Case of Ossification of the Auricle, by Dr. G. B. McAuliffe; Report of a Case of Acute Mastoiditis. Death from Meningitis. Post Mortem Examination, by Dr. Arnold Knapp; Preliminary Report of a Case Presenting Menière's Symptoms for Five Years. Result to Date of Operation of Ossiculectomy, by Dr. P. D. Kerrison; paper: The Dangers of Attempting to Curette the Jugular Bulb Prior to Ligation of the Jugular Vein in Operations Upon the Sigmoid Sinus, by Dr. J. D. Richards. Emil Gruening, M. D., chairman; W. H. Haskin, M. D., secretary, 42 East Forty-first Street.

The Section in Medicine will meet on Tuesday, April 18th, at 8.15 p. m. Order: Presentation of Cases and Specimens; Clinical Reports: (a) Pernicious Anæmia with Exhibition of Case, by Dr. Theodore C. Janeway; (b) Hæmophilia, by Dr. Harlow Brooks; papers: Analysis of Forty Cases of Arthritis, with Special Reference to the Diagnosis of Gout and Rheumatism, by Dr. Charles C. Ransom; discussion by Dr. Townsend, Dr. Potter, and others; An Introduction to the Bacteriology of the Typhoid Colon Group of Bacilli, by Dr. B. H. Buxton; On the Impossibility of Differentiating So Called Paratyphoid from Typhoid Fever Except by a Bacteriological Examination of the Blood, by Dr. Warren Coleman; discussion by Dr. W. G. Thompson, Dr. Meltzer, Dr. Brill, Dr. Manges, Dr. Ewing, Dr. Park, and others. Charles H. Lewis, M. D., chairman; E. E. Smith, M. D., secretary, 26 East Twenty-ninth Street.

PHILADELPHIA.

Change of Address.—Dr. Rufus B. Scarlett, to 4242 Chestnut Street.

Woman's Medical College.—Dr. Gertrude A. Walker has resigned the position of clinical professor of ophthalmology in the Woman's Medical College of Pennsylvania; Dr. Anina C. Rondinella has resigned the positions of demonstrator of ophthalmology and assistant demonstrator of pathology.

Charitable Bequest.—By the will of Meyer Guggenheim, who died at Palm Beach, Fla., on March 16th, the Jewish Hospital of Philadelphia receives \$20,000. The money will be used for improvements in the Guggenheim Private Hospital, which was founded by a gift of \$80,000 from the testator in 1903.

The Society of Normal and Pathological Physiology, University of Pennsylvania, offered the following programme at its meeting held April 3rd: Knee Jerks Without Stimulation of the Patellar Tendon, by Dr. E. B. Twitmyer; A Study of the Initial Stage of Voluntary Movements of Extension and Flexion, by Mr. Robert H. Gault.

Nurses Graduate.—The commencement exercises of the Pennsylvania Hospital Training School for Nurses were held on March 30th, at the hospital, Eighth and Spruce Streets. Dr.

Alfred Stengel delivered the address. After the formal exercises the graduating class held a reception. The following young women finished their course of training:

Ida F. McBride, Sara Virginia Kenley, Parmelia M. Doty, Cora Mae Acker, Beulah May Cope, Martha Mills, Jennie Clapp, Ethel Van Harlingen, Clara Newby, Helen Maud Fair, Anne O. Richards, Margaret Wagenhurst, Edith F. Krause, Helen E. Sprecher, Margaret Stuart, Anna Van Valkenburg, Julia McL. Cruikshank, Florence E. Owen.

Scientific Society Meetings for the Week Ending April 15, 1905.—Monday, April 10th, Section on General Medicine, College of Physicians; Wills Hospital Ophthalmic Society. Tuesday, April 11th, Kensington Branch, Philadelphia County Medical Society; Philadelphia Pædiatric Society; Botanical Section, Academy of Natural Sciences. Wednesday, April 12th, Philadelphia County Medical Society. Thursday, April 13th, North Branch, Philadelphia County Medical Society; Pathological Society. Friday, April 14th, Northern Medical Association; West Philadelphia Medical Association. Saturday, April 15th, West Philadelphia Branch, Philadelphia County Medical Society.

Death.—Dr. William H. Warder died at his home, 1212 North Broad Street, on March 28th, aged 71 years. Dr. Warder graduated from the University of Nashville in 1859. He came to Philadelphia from the South in 1864 and identified himself with the Jefferson Medical College, where he quizzed in obstetrics and surgery. Dr. Warder was a member of the obstetrical staff of the Philadelphia General Hospital from 1874 to 1881. He was a member of the Pennsylvania State Medical Society, the Philadelphia County Medical Society, the Obstetrical Society, and the Medical Club.

The Health of the City.—The following cases of transmissible diseases were reported to the Bureau of Health for the week ending March 25, 1905:

	Cases.	Deaths.
Malaria fever.....	0	0
Typhoid fever.....	306	17
Scarlet fever.....	48	1
Smallpox.....	1	0
Chickenpox.....	66	0
Diphtheria.....	54	9
Cerebrospinal meningitis.....	7	2
Measles.....	28	1
Whooping cough.....	12	3
Tuberculosis of the lungs.....	48	51
Pneumonia.....	87	51
Erysipelas.....	12	0
Puerperal fever.....	2	1

The total death rate was 531, in an estimated population of 1,438,318, corresponding to a yearly mortality of 19.19 per 1,000 population. The total infant mortality was 117; under one year, 96; between one and two years, 21. There were 36 still births, 23 males and 13 females. The following deaths from other transmissible diseases were reported: Tuberculosis, other than tuberculosis of the lungs, 10; dysentery, 1; diarrhoea and enteritis, under two years, 23. The increase in the number of cases of typhoid fever in the districts described last week continues. The temperatures have been higher and there was 1.07 inches of rain falling during the week. On Sunday evening, March 19th, there was a sharp thunder storm, the first of the year.

Some Legislation Affecting the Public Health.

—The State legislature now in session at Harrisburg passed a bill on March 30th, permitting the use of certain maximum proportions of sodium benzoate and of harmless vegetable coloring matter in fruit syrups and fruit products for use in soda water, "soft" drinks, and ice creams. It is to be hoped that the governor will use his veto power on this measure. He has vetoed the measure, reported in these columns last week, to allow of the castration of idiots. A bill to permit the State Live Stock Sanitary Board to conduct scientific investigations in relation to the causes, nature, and prevention of diseases of domestic animals has met with the governor's approval.

American Society of Tropical Medicine.—The second annual meeting of the American Society of Tropical Medicine was held at Philadelphia on March 24, 1905. The following scientific programme was offered:

Dr. Seneca Egbert, The History of the Republic of Panama and of the Panama Canal; Dr. Joseph McFarland, The Canal Zone; Dr. Roland G. Curtin, Medical Conditions of the Isthmus of Panama.

At the business meeting which preceded the scientific meeting the following resolution, which is to be sent to the proper authorities, was adopted:

The American Society of Tropical Medicine, at the suggestion of Sir Patrick Manson, of London, one of its honorary members, begs to call your attention to the fact that the investigations of the past decade have so increased our knowledge of malaria, yellow fever, hook worm disease, and other tropical diseases as to make their prevention quite possible by the exercise of comparatively simple measures, and begs to recommend as a means toward the diminution and extinction of these maladies, that a certain amount of information regarding them be included in the curriculum of the public schools in our tropical colonial possessions.

The following officers were elected for the ensuing year:

President, Dr. Roland G. Curtin, of Philadelphia; vice-presidents, Dr. Victor C. Vaughan, of Ann Arbor, and Dr. William S. Thayer, of Baltimore; treasurer, Dr. Wharton Sinkler, of Philadelphia; secretary, Dr. Joseph McFarland, of Philadelphia; assistant secretary, Dr. John M. Swan, of Philadelphia; councilors, Dr. Thomas H. Fenton, of Philadelphia; Dr. James M. Anders, of Philadelphia; Dr. Judson Daland, of Philadelphia; Dr. Ramon Guiteras, of New York, and Dr. B. F. Stahl, of Philadelphia.

The next annual meeting will be held in March, 1906.

Future of the Free Hospital for Poor Consumptives.

—At the annual meeting of the Free Hospital for Poor Consumptives, held March 13th, Dr. Lawrence F. Flick outlined plans for broadening the scope of the institution, provided the legislature appropriated the \$300,000 which were asked for. Later, in presenting himself before the committee of the legislature having the appropriation under consideration, Dr. Flick was treated with such discourtesy as to make it apparent that this appropriation would not be granted, and the announcement has been made that the institution will at once be placed on a paying basis. On March 1, 1904, there were 100 patients in the sanitarium; 281 were admitted in the year, 204 were discharged, 63 left, and one died. The total cost of maintenance was \$31,-

989.11. A table bearing on the progress of the patients while at the institution follows:

Deaths	1
Improved	58
Much improved	62
Disease arrested	101
Not improved	32

The following officers were elected: President, Dr. Lawrence F. Flick; vice-presidents, Louis Gerstley and M. S. Kemmerer; secretary, Charles W. Welsh; treasurer, Edward A. Millar; managers, James M. Willcox, Tatnall Paulding, Frank Graham Thompson, Talcott Williams, Benjamin Wolf, Samuel Castner, Jr., Dr. C. J. Hatfield, Dr. John K. Mitchell, Dr. D. J. McCarthy, and Dr. Joseph Walsh. The failure of this appropriation is to be regretted by all who have the interests of the control of pulmonary tuberculosis in Pennsylvania at heart. The Free Hospital is well established, and has done an excellent work, so far as its means have permitted, and it seems wiser to encourage such a well established institution than to give the amount of money asked for to an institution which does not yet exist.

GENERAL.

Change of Address.—Dr. A. A. Gillette, to 511 North Washington Street, Rome, N. Y.

Dr. F. E. Prewitt has been appointed police surgeon to the force of Denver, Colo.

Dr. Gilbert E. Seaman, of Milwaukee, has been appointed surgeon major of the first regiment, W. N. G.

Epidemic in Louisville, Ky.—There is said to be a severe epidemic of follicular amygdalitis in Louisville.

Illness of Professor Edward S. Wood, of Boston.—Dr. Edward S. Wood, professor of chemistry at the Harvard Medical School, upon whom an exploratory laparotomy was performed a few days ago, is convalescent, and will leave the hospital in a short time. The nature of the abdominal trouble is, however, said to be serious.

Nurses Graduate in Kansas City.—The following young women graduated as trained nurses from the Training School for Nurses of the Kansas City Hospital on April 4th: Elizabeth W. Canfield, Mary P. Hetrick, Elvia M. Patton, Nellie Holmes, Lulu B. Hunt, Emma D. Sandell, Josephine Reidy.

Council of Physicians and Surgeons of New Brunswick, Can.—A meeting of the Council of Physicians and Surgeons of New Brunswick was held at Fredericton on March 27th. The following officers were elected: President, Dr. Atherton; treasurer, Dr. Walker; registrar, Dr. Skinner.

Professor Osler's Successor.—The trustees of the Johns Hopkins University have elected Dr. Lewellyn Franklin Barker, now head of the department of anatomy in the University of Chicago and in Rush Medical College, to the professorship of medicine made vacant by the resignation of Dr. William Osler.

Gaillard's New Title.—Since the amalgamation of *Southern Medicine* and *Gaillard's Medical Journal*

(in October, 1904) it has been decided to consolidate the name to *Gaillard's Southern Medicine*, published by Gaillard's Southern Medicine, Inc. The officers of the incorporation are William Edwards Fitch, M. D., president and treasurer; M. C. Fitch, vice-president, and E. W. Fitch, secretary. We wish our contemporary every success under its new name.

American Physician Appointed to the Vatican.

—Dr. William A. Dunn, of Boston, has become a member of the medical and surgical staff of the Vatican. Dr. Dunn is 50 years old and graduated from Harvard Medical School in 1875. After studying abroad for some time he returned to Boston, where he built up a practice. His attainments have secured him the place of consulting physician with the chief medical attendant of Pope Pius X.

Hampton County, S. C., Physicians Organize.

—The physicians of Hampton met on March 23rd, the counties of Hampton, Beaufort, Colleton, and Dorchester being represented. Dr. Southwood Smith was elected president; Dr. J. L. Folk, vice-president; Dr. C. A. Rush, secretary and treasurer. Dr. M. B. Mouson was elected delegate to the State Medical Association, which will meet at Greenville, April 12th. The following were elected censors: Dr. J. W. Colson, Dr. C. P. Walter, Dr. C. R. Peebles.

The Proposed General Military Hospital.—It is understood the commission appointed to select a site for the general military hospital, for which an appropriation of \$100,000 was made at the last session of Congress, has decided upon the tract of land lying on the west side of the Seventh Street Road, about opposite the national cemetery known as the Battle Cemetery, a short distance above Brightwood, D. C. The tract contains ninety-one acres and has a broad frontage on the Seventh Street Road and runs back to the line of Sixteenth Street extended.

Medical and Chirurgical Faculty of Maryland.

—Dr. William Osler will make his last public appearance on the afternoon of Thursday, April 27th, when he will deliver the annual oration of the Medical and Chirurgical Faculty of Maryland. The lecture will begin at 4.30 o'clock, and will be delivered in the large assembly room of McCoy Hall, Johns Hopkins University. The anniversary meeting, marking the one hundred and seventh year of the faculty, will be held April 25th, 26th, and 27th, and will be a farewell to Dr. Osler. An interesting programme of medical papers and discussions is being prepared.

The Fifteenth International Medical Congress will be held at Lisbon in April, 1906. At a meeting of the National American committee, held at St. Louis last September, officers and members were appointed to represent the Congress. The executive committee are Frank Billings, M. D.; William Osler, M. D.; Frederick Shattuck, M. D.; Abram Jacobi, M. D.; and J. H. Musser, M. D., chairman. Any communications regarding the presentation of papers at this congress can be sent to Miguel Bombarda, secretary

at Lisbon, or to Dr. Ramon Guiteras, secretary for this country. John H. Musser, M. D., chairman; Ramon Guiteras, M. D., secretary.

Assistant Surgeons for the Navy Graduated.

—The following have graduated as assistant surgeons from the Navy Medical School at Washington:

H. W. Smith, of Massachusetts; Eugene A. Vickery, of Massachusetts; Harry F. Hull, of Colorado; William A. Angwin, of California; James L. Belknap, of Massachusetts; Norman T. McLean, of Massachusetts; Richard Beck Chapman, of California; Robert Graham Heiner, of the District of Columbia; Robert Earl Stoops, of Ohio; George Lewis Wickes, of New York; William John Zalesky, of Iowa; Lewis Hawley Wheeler, of Connecticut; Henry Agett May, of Maryland; William Dunlop Owens, of the District of Columbia; Owen Joseph Mink, of Illinois; Frederick Eugene Porter, of Tennessee; Carey Travers Grayson, of Virginia; Wrey Gilmor Farwell, of New York; David Clark Cather, of Virginia; William Neil McDonnell, of Minnesota; Addison Bertram Clifford, of Michigan; Clarence Edward Strite, of Maryland; Howson White Cole, Jr., of Virginia.

Statement of Mortality in Chicago for the Week Ending April 1, 1905, compared with the preceding week and with the corresponding week of 1904. Death rates computed on United States Census Bureau's estimated midyear populations of 1,990,750 for 1905 and of 1,932,315 for 1904:

	April 1, 1905.	March 25, 1905.	April 2, 1904.
Total deaths, all causes.....	577	581	576
Annual rate per 1,000.....	15.11	15.21	15.58
By sexes.....			
Males.....	323	322	341
Females.....	254	259	235
By ages.....			
Under 1 year.....	134	126	91
Between 1 and 5 years.....	54	58	37
Over 60 years.....	122	109	117
Important causes of death.....			
Acute infectious diseases.....	30	24	25
Apoplexy.....	17	12	23
Bright's disease.....	56	37	36
Bronchitis.....	21	22	21
Consumption.....	69	81	80
Cancer.....	21	27	32
Convulsions.....	19	16	11
Diphtheria.....	6	4	4
Heart diseases.....	45	36	36
Influenza.....	4	7	5
Measles.....	11	2	0
Nervous diseases.....	20	27	30
Pneumonia.....	106	106	124
Scarlet fever.....	1	0	5
Smallpox.....	1	2	0
Suicide.....	11	7	11
Typhoid fever.....	6	5	4
Violence (other than suicide).....	25	25	22
Whooping cough.....	12	9	0
All other causes.....	98	132	117

Public health conditions at the end of the week and of the month continue fairly satisfactory. There is some decrease of the hospital population, especially of typhoid fever and pneumonia. The worst of the pneumonia season is over and consumption will soon again resume its lead as cause of the greatest number of deaths. Between November 1, 1904, and April 1, 1905—154 days—there were 2,263 deaths reported from pneumonia and 1,384 from consumption. During the corresponding period of 1903 to 1904, there were 2,666, or 403 more, pneumonia deaths and 1,295, or 89 fewer, deaths from consumption. At the close of office hours Saturday, April 1st, there had been 3,657 deaths from consumption reported in New York city and 5,700 from pneumonia during the 154 days of the current pneumonia season. Chicago is especially favored, by comparison, in respect of these two diseases, as well as of cerebrospinal fever.

Pith of Current Literature

SEMAINE MEDICALE.

March 1, 1905.

1. Anaphylaxis, By Professor R. LEPINE.
2. Treatment of a Crushed Hand, By Dr. F. LEJARS.

1. **Anaphylaxis.**—Lepine says that after the administration of a drug three results may follow; there may be a return of the organism to the status quo ante, there may be developed a habituation, or tendency to immunity against a similar dose, in other words, prophylaxis, or there may be developed an exactly opposite tendency which Richet has named anaphylaxis. Some diseases seem to be anaphylactic, such as grippé, as it is a matter of common observation that persons who have once suffered from this disease are more prone to other attacks. The writer says that perhaps the idea of anaphylaxis may be of use in the domain of pathology, but he does not show how it is of any practical value.

2. **Treatment of a Crushed Hand.**—Lejars advises to anesthetize the patient, apply Esmarch's bandage, cleanse the wound and neighboring parts thoroughly, remove all foreign bodies and débris of whatever nature, bits of bone, flesh, etc., amputate any portion which has been crushed beyond hope of recovery, readjust the tissues as nearly as possible to their normal condition, suturing the divided tissues when necessary, remove Esmarch's bandage, check hemorrhage, drain freely, and apply a sterile dressing.

LYON MEDICAL

March 12, 1905.

1. The Weight of Certain Organs in Diabetics, By R. LEPINE.
2. Gastrostomy in Certain Forms of Peritonitis, By JABOULAY.
3. Myelitis from Tuberculous Toxines, By CLEMENT.

1. **Weight of Organs in Diabetics.**—Lepine examined the internal organs of 36 patients who died of diabetes and obtained the following results:

Heart, small (less than 270 grammes for men and 250 grammes for women).....	17
Heart, large.....	14
Heart, normal.....	5
Spleen, normal.....	10
Spleen, below normal weight.....	8
Spleen, above normal weight.....	18
Liver, normal.....	10
Liver, greatly increased.....	13
Liver, small.....	8
Liver, pathologically changed.....	5
Kidney, normal.....	11
Kidney, over 400 grammes, but proportional to the weight of the liver and spleen.....	8
Kidney, very large in proportion to the other organs and to the weight of the patient.....	10
Kidney, pathologically changed.....	8

2. **Gastrostomy in Certain Forms of Peritonitis.**—Jaboulay reports a case of septic peritonitis complicating an operation for intestinal obstruction in which gastrostomy was successfully performed to control the vomiting and prevent distention of the stomach with consequent pressure on the neighboring parts.

3. **Myelitis from Tuberculous Toxines.**—Clement reports six cases, and states as his conclusions that myelitis occurs in the same way as peripheral toxic neuritis in the tuberculous, and

is usually tabetic in appearance. In most cases the nervous phenomena, especially at the beginning, mask the pulmonary trouble to both the patient and the physician. It may therefore be said to be an initial lesion of phthisis of the tabetic or spasmodic type. The nervous symptoms develop slowly and never result in complete locomotor ataxia, but remain perhaps for years resembling incipient tabes. The pulmonary tuberculosis seems to develop more slowly than usual, but in two of the cases here reported it ran a very rapid course.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

April 1, 1905.

1. Acute Meningitis, By W. T. COUNCILMAN.
2. The Surgical Aspects of Major Neuralgia of the Trigeminal Nerve. A Report of Twenty Cases of Operation of the Gasserian Ganglion, with Anatomical and Physiological Notes on the Consequences of Its Removal (Continued), By HARVEY CUSHING.
3. Fluorescence Artificially Produced in the Human Organism by the X Ray, by Radium, and by Electric Discharges, as a Therapeutic Method, By WILLIAM JAMES MORTON.
4. The Diagnosis and Treatment of Perforation in Typhoid Fever, with a Report of Nineteen Cases, of Which Sixteen Were Operated on, with Five Recoveries, By MORRIS MANGES.
5. Early Diagnosis and Operative Treatment of Gastric Cancer, By G. W. McCASKEY.
6. Some Complete Urine Analyses, By J. H. LONG.
7. Immunity. Chapter X.

1. **Meningitis.**—Councilman writes on the pathology and bacteriology of acute meningitis. He does not concern himself with the symptomatology and treatment of the disease. While acute meningitis may be produced by a number of microorganisms, three are most generally concerned in its production. They are the pneumococcus, streptococcus, and meningococcus of Weichselbaum. It is the latter coccus which is at present of so much concern. The evidence which we have justifies us in the conclusion that there is a form of meningitis produced by the *Diplococcus intracellularis meningitidis*, that the epidemics of acute meningitis are due to this organism, that sporadic cases are not infrequent, that, with rare exceptions, primary cases of meningitis are due to this organism; that recovery takes place much more frequently in this type of disease than when infection is due either to the pneumococcus or the streptococcus, that the disease is more common than is generally supposed, that the organism does not live as a saprophyte outside the body, that the organism may be found on the mucous membrane of the nose, where it may produce a rhinitis, and that it is probable that infection of the meninges takes place by extension from some of the adjacent mucous membranes by means of the lymphatics. We can only explain the epidemics of the disease by the assumption that at certain times the power of infection is increased either by an increase in the virulence of the diplococcus or by a decrease in the resistance of the tissues.

3. **Fluorescence.**—Morton summarizes his

paper thus: (1) The excitation of fluorescence within tissue is a species of phototherapy and depends on the same basis for curative effects. The term sensitization is not accurate, for it is not known what the term means. There is no proof that fluorescent substances make the cells or other microorganisms vulnerable to the exciting radiation. (2) What the fluorescent light lacks in intensity is compensated for by propinquity to tissue. (3) The methods of Tappeiner, 1900, followed by Dreyer, 1903, consist primarily of superficial applications, or of parenchymatous injections submitted to the action of sunlight or to the action of the electric arc light. (4) The method here outlined consists of a medicinal saturation of the entire blood system with a fluorescent solution, and submission of parts or of the whole of the patient to the Röntgen and Becquerel radiations and to electric discharges. (5) The method naturally includes filling cavities with fluorescent solutions, as well as using these solutions medicinally. (6) This method is not of the same category as sensitization by Dreyer's method, for the process and the results are different. (7) The curative effects obtained by this method are probably due to the fluorescent light. (8) This method permits of an improvement in skiagraphic effects and of fluoroscopic examinations. (9) Following the suggestions of the use of fluorescent solutions in diagnosis and treatment, the method has proved of value in determining the position and size of the stomach and other cavities of the body. (10) The thoracic cavity presents on the fluoroscope a degree of illumination greater than that produced by the x radiation alone. (11) The method is useful in tuberculosis of the lungs, and in other cases of tuberculous deposit, as well as in cancer.

4. **Perforation in Typhoid.**—Manges emphasizes the need of more closely watching all cases of typhoid fever, so that the first symptoms of perforation will not occur unheeded. It is impossible to formulate rules for guidance in reaching a diagnosis of perforation. It has often been said, and it is undoubtedly true, that the so called absolute signs of perforation are in reality the signs of the resulting peritonitis. Sudden pain, vomiting, and obliteration of the liver dullness are the most characteristic signs of perforation. With experience and care a correct diagnosis is not very difficult, and a strong suspicion of perforation justifies recourse to operation.

BOSTON MEDICAL AND SURGICAL JOURNAL.

March 30, 1905.

1. The Results of Medical Treatment of Peptic Ulcer at the Boston City Hospital. By GEORGE G. SEARS.
2. Angeioneurotic Œdema: Report of a Case Operated Upon During an Abdominal Crisis.
By FRANCIS B. HARRINGTON.
3. Observations on Pneumonia with a Report of Two Fatal Cases of Extrapulmonary Suppuration. Suggestions for Treatment, By DANIEL E. KEEFE.
4. Eclampsia, By WARREN R. GILMAN.

1. **Peptic Ulcer.**—Sears concludes: (1) That the strongest argument so far presented in favor of the surgical over the medical treatment of pep-

tic ulcer is the failure of the latter. (2) That the danger to the patient from operation in skilled hands is not greatly increased, the immediate results of both medical and surgical treatment being about the same. (3) That the future interest to the clinician lies, not in hearing of the prowess of the surgeon, recorded in long series of successful operations, but in learning their end results. Until they are known conservatism seems the proper course, but when medical treatment has failed, as shown by the recurrence of repeated small hæmorrhages or the persistence of other symptoms, a resort to operation is legitimate and justifiable. (4) That the surgical treatment of hæmorrhage is of questionable utility, since in many cases it has continued, or first appeared, after operation, and in some, at least, of the successful ones it is doubtful if operation had any influence for good. (5) That the interests of the patient will be best served, when doubt arises as to the advisability of operation, if the decision is not left to the physician or surgeon alone. Only by their cooperation will it be possible to avoid either the sacrifice of life from unnecessary delay, or the performance of useless or even harmful operations.

2. **Angeioneurotic Œdema.**—Harrington reports a case of angeioneurotic œdema which came to operation on account of an acute abdominal crisis. At operation the following condition of affairs was found: There was a good amount of clear free fluid among the intestines and filling the pelvis. The intestines themselves were engorged with blood, and so red that a mild peritonitis was at first suspected. There were no hæmorrhagic areas in the intestinal walls, but at a point within a short distance of the ileocecal valve, a cylindrical enlargement of the ileum $2\frac{1}{2}$ inches long was brought to light which entirely surrounded the gut, increasing the bowel circumference to twice its ordinary size. The swelling was evidently in the bowel wall, elastic to touch and did not pit upon pressure. It can be easily understood how such an infiltration could derange peristaltic action of the intestine. The engorgement of the intestines and the free fluid were explained by the violent peristalsis brought on in the effort to force down the lesion which was actually in the intestinal wall. There was no distention above the lesion, since the finger could be easily passed into the swelling at either end. The patient recovered from the operation.

3. **Pneumonia.**—Keefe is in the habit of treating pneumonia according to the following plan: Patients are instructed to lie, not on the affected side, but on the side of the sound lung, thus favoring the emptying of the vessels of the lung by means of gravitation, while ice is applied to the affected side. The medicinal treatment, especially the first stage, should consist of: (1) One active purge; (2) wet or dry cups or leeches; (3) free use, all over affected lung, of as strong counterirritants as can be comfortably borne; (4) veratrum viride to bleed the lungs into the abdominal and general capillaries, or the direct abstraction of blood from a vein followed, if need be, by infusion. For the remainder of the disease we are

virtually powerless. There may be a moment when a dose of digitalis, ammonia, or whiskey may do good, but the author has not been able to find it. It is not before the latter part of the second or third stage. A few doses of morphine may be indispensable in pleuropneumonia. Plenty of fresh air should be admitted, but the body covering should be sufficient to promote perspiration and dilatation of the superficial capillaries.

AMERICAN MEDICINE.

April 1, 1905.

1. Treatment of Cerebrospinal Fever,
By CHARLES G. STOCKTON.
2. A Dissertation on Temperament, Diathesis, Dyscrasia,
Predisposition, Cachexia, Susceptibility, Idiosyncrasy,
and Heredity, By HOMER WAKEFIELD.
3. On Peritoneal Adhesions, By CARL BECK.
4. The Treatment of Hæmoptysis, By FRANCIS HARE.
5. Some Observations Upon the Treatment of Chronic Dis-
eases, By CURRAN POPE.
6. An Interesting Tumor and Its Relations to Heredity,
By HENRY E. RADASCH.
7. Papillomas in Syphilitic Child, Occluding Both Nostrils,
By W. G. B. HARLAND.

1. **Cerebrospinal Fever.**—Stockton concludes that when we recollect the difference in virulence in different epidemics, it is easy to understand how faulty notions of the effects of treatment may gain credence. A review of the subject seems to warrant the conclusion that benefit does follow certain measures and that the most useful procedure is to bring about the best hygienic condition for the patient, that is: (1) Absolute quiet in well ventilated, darkened rooms, with the absence of all excitement and irritation. (2) Giving the greatest attention to secure the proper performance of the various functions of the body. (3) The trial of the hot baths after the method of Aufrecht in all cases in which they seem to do good. (4) The practice of intraspinal puncture, with drainage when necessary to relieve severe pressure symptoms, to be repeated, if necessary, provided benefit follows the first puncture. (5) The use of antipyrine in cases in which the temperature is raised, not only for the relief of this symptom, but for the mitigation of headache and hyperæsthesia. This drug is also useful in improving the mental state, and it is not followed by depression. (6) The use of opium or the bromides alone, or in connection with antipyrine for the relief of convulsions, pain, hyperæsthesia and pressure symptoms generally, which are not relieved by the foregoing methods of treatment. (7) The use of mercury when needed for its laxative effect, or to assist elimination.

3. **Peritoneal Adhesions.**—Beck's paper consists of cursory remarks he made during the discussion of a paper read in a local medical society. Peritoneal adhesions are easier to prevent (by early operation) than to deal with when once formed. The author's experience with cases of chronic progressive adhesion-forming peritonitis, as it is observed idiopathically as well as after appendicitis, is absolutely bad. The nature of this condition demands further study.

4. **Hæmoptysis.**—Hare reports nine cases of hæmoptysis (eight tuberculous and one from mitral disease) treated with amyl nitrite inhalations. In all sixteen attacks of hæmorrhage were combated. In fifteen of the cases the hæmorrhage ceased inside of three minutes, in one case inside of ten minutes. There was in no case immediate recurrence of bleeding after the drug had expended its power.

5. **Chronic Disease.**—Pope asserts that there would be less chronic disease if the profession put less faith in drugs and more in rational and pain-taking treatment. The best means of combating chronic disease are, in the order of their importance: (1) Hydrotherapy, local and general; (2) electric currents, local and general, high frequency, galvanic, faradaic, sinusoidal, static, static wave; (3) massage and vibration, local and general; (4) exercise and gymnastics, local and general; (5) hygiene and diet; (6) rest, freedom from worry and work; (7) control and individual influences; (8) medicinal measures.

MEDICAL NEWS.

April 1, 1905.

1. The Coagulation of the Blood, By LEO LOEB.
2. Nephritis Complicating Mumps,
By JAMES ALEXANDER MILLER.
3. The Status of Suprarenal Therapy,
By SAMUEL FLOERSHEIM.
4. The Specific Therapy of Tuberculosis,
By CHARLES DENISON.
5. Intestinal Ileus with Strangulation. By R. R. HUGGINS.
6. Report of a Case of a Large Parovarian Cyst, and Two Cases of Large Ovarian Cysts,
By FRANK C. HAMMOND.

1. **Coagulation of the Blood.**—Loeb reviews the more recent investigations regarding the coagulation of the blood, reports some of the more important facts and briefly considers what is usually termed the "therapy of the coagulation of the blood," which comprises, however, only one phase of the process of coagulation. The blood of invertebrate as well as of vertebrate animals is studied. The paper is fragmentary in character and only considers certain aspects of the problem.

2. **Nephritis in Mumps.**—Miller reports the following case: Acute exudative nephritis in the course of mild double parotiditis, in a boy four years old, with a marked family predisposition to kidney disease, occurring in the twelfth day of the parotiditis, which was further complicated on the eighteenth day by a moderately severe attack of measles. The measles exercised no influence upon the nephritis, which entirely disappeared in thirty-five days, and after several months had not recurred. There are thirty similar cases on record and a summary of them is given. The author concludes: (1) Acute nephritis complicating mumps may occur in either children or adults, and is much more frequent in males than in females. (2) The parotiditis is usually double, mild in character, and the nephritis is more liable to occur during early convalescence. Exposure to cold

may be a predisposing factor. (3) The nephritis is usually moderately severe, of less than one week's duration, and ending in complete recovery. Rarely it may develop into chronic nephritis, or it may be so severe as to cause death. (4) This complication of mumps is infrequent, but probably not as rare as usually considered. Febrile albuminuria is probably very common in mumps, but this, as well as more serious kidney lesions, is probably often overlooked. (5) Careful urine examinations should be made, and strict precautions against exposure should be taken, in all cases of mumps, both during the acute symptoms and during convalescence.

3. Suprarenal Therapy.—Floersheim asserts that there are no contraindications to the exhibition of preparations of the suprarenal glands. He believes that some of the stable preparations are of the greatest utility in very many different conditions, and that their use should be better understood.

5. Intestinal Ileus.—Huggins reports four cases of ileus with strangulation. Two of the patients died and two recovered. The paper is a plea for early diagnosis and early operation.

MEDICAL RECORD.

April 1, 1905.

1. The Relation of the Nervous System to Visceral and Trophic Phenomena, By JOSEPH FRAENKEL.
2. Perinæorrhaphy and Prolapse, By ARNOLD STURMDORF.
3. Compound Traumatic Separation of the Lower Epiphysis of the Femur, By GILBERT GEOFFREY COTTAM.
4. The Value of the Present Quantitative Tests for Hearing; with the Demonstration of a New Apparatus, By W. SCHIER BRYANT.
5. The Rapid Bacteriological Diagnosis of Diphtheria, By HENRY A. HIGLEY.
6. The Best Method of Administering Potassium Iodide, By MAX HÜHNER.
7. A New Remedy for Ulcerative Processes, Acute and Chronic, Including Pulmonary Tuberculosis, By HUBBARD W. MITCHELL.

1. Relations of the Nervous System.—Fraenkel attempts to define the relations of the nervous system (the cerebrospinal or somatic, and the vegetative, or as Langley calls it, the automatic) to the pathology of the vegetative functions. The paper, owing to its scope, is necessarily fragmentary in character, and does not lend itself to condensation. The author holds that a thorough study of the influence of the nervous system on vegetative functions and its dependence upon them promises the following results: (1) Greater exactness of localization of organic disease of the nervous system and better interpretation of early symptoms. (2) More rational conception of functional conditions. (3) Clearer therapeutic indications.

2. Perinæorrhaphy.—Sturmdorf asserts that a perfect restoration of the pelvic floor after laceration is not to be hoped for unless it is possible to unite each of the severed tissues to each other. This can never be accomplished, save by an immediate operation. Even then the difficulties may

be insurmountable unless guide sutures are applied before the perinæum is torn. He advises therefore introducing three or four silk sutures through the perinæum before the child is born. If no tear occurs the stitches are easily removed. There is no best operation for the repair of an old perineal tear. Each case should be studied separately and operated upon according to circumstances. This implies, on the part of the operator, an adequate knowledge of the mechanism of prolapse of the pelvic organs. The author propounds some theories of his own regarding intraabdominal tension.

3. Epiphyseal Separation.—Cottam reports two personal cases of traumatic separation of the lower epiphysis of the femur. Both these cases were subjected to operation and both recovered. In the first case the deformity was considerable. The second case is of such recent date that ultimate results cannot be predicted.

4. Tests for Hearing.—Bryant has devised a special type of phonograph for use in testing the hearing. The instrument is not described. The author thus summarizes his paper: "The methods at present in use do not give adequate tests for the perception of the human voice, nor do they give results which can be compared. My phonographic acoumeter does all of these things, and more. It overcomes the chief difficulties and inaccuracies formerly accompanying quantitative hearing tests. It gives a satisfaction and accuracy not hitherto attained. It furnishes a test with the human voice which does not vary and can be multiplied and repeated indefinitely. Unilateral as well as bilateral tests can be applied without doubt or error. Eyesight aids are eliminated. It furnishes a universal standard, whose records are always comparable. It furnishes a sure way of detecting all feigned deafness short of total bilateral deafness; and it is an ideal machine for furnishing acoustic exercise which has been recommended in the treatment of deafness."

5. The Diagnosis of Diphtheria.—Higley describes in detail a rapid method of diagnosing diphtheria from the examinations of stained slides made directly from the diseased membrane. The author emphasizes the fact that the method he advocates is not suited to the uses of the average clinical practitioner, as it requires the skill of the trained laboratory worker to get good results from it.

7. A New Remedy.—Mitchell advocates the use of a preparation he has devised. The substance is non-toxic, can be used internally or externally, and is prepared as follows: To a convenient quantity of water add 3 per cent. sodium chloride, 0.1 per cent. bromine, and 0.5 per cent. hydrochloric acid (C. P.). Subject this mixture to the action of an electrical current until such chemical action has taken place within the mixture as to convert all free bromine into a compound with the other elements present. The length of time necessary for this depends upon the amount of fluid acted upon and the strength of the current used. The resulting fluid is pale amber in color, with a strong odor of chlorine, a

slightly acid taste, and a sp. gr. of 1022. It must be kept in amber colored bottles, in a cool place, and tightly corked.

11. The Pathology of Puerperal Fever, By FOULERTON.
12. The Blood in Puerperal Fever, By EMERY.
13. On an Epidemic of Puerperal Fever a Century Ago, By HELLIER.

[This "symposium" will be found interesting and important, and is therefore abstracted with a view to comprehensiveness.]

1. **The Clinical Aspects of Puerperal Fever.**—Herman defines the disease as one which results from the inoculation of wounds with pathogenic organisms. Puerperal ulcers may be present upon the vaginal mucous membrane, with false membrane and fever. Hospital gangrene, with fever and prostration, is now rarely seen. Spreading traumatic gangrene is also rare. It is accompanied with false membrane and suppurative inflammation of the veins, lymphatics, and muscular structure of the uterus. It quickly extends to other tissues and is usually fatal. Sapræmia is a local poisoning which disappears when the infecting cause is removed. Septicæmia means the entrance of toxic microbes into the blood with intense systemic disturbance. It is usually quickly fatal. Pyæmia usually results from uterine phlebitis. Fever is intense, and there are many secondary abscesses. Death is the usual result. Peritonitis quickly follows delivery, from direct injury, from the extension of endometritis or from extension of inflammation of the pelvic cellular tissue and uterine muscular tissue. It is usually quickly fatal. Late peritonitis may be caused by substances retained in the uterus, by the extension of gonorrhœa, or by the injury to a preëxisting tumor or abscess during labor, the inflammatory symptoms being deferred until a week or longer from the occurrence of labor. Pelvic cellulitis usually develops rapidly to peritonitis, and may be quickly fatal or it may result in a chronic condition resulting in absorption or suppuration, surgical interference being eventually required in the latter case.

2. **The Treatment of Puerperal Fever.**—Galabin considers local disinfection the first step to be taken, sores and ulcers being treated according to the intensity of the local lesion. A specimen

of the secretion from the uterus should be submitted to microscopical examination and culture. The uterus should be irrigated with an antiseptic fluid if the temperature exceeds 102° F. The bowels should be opened with calomel, followed by sodium sulphate. If the temperature reaches 103° or 104° F., the uterine cavity should be explored with the finger. This is better than repeated irrigation or curettage. The curette may be used if the finger detects substances which it cannot remove. Plugging with iodoform gauze is advisable if bleeding is persistent. The diet should be principally fluid, abundant, and administered in feedings at short intervals. Saline injections into the rectum or cellular tissue are frequently beneficial. Cold, quinine, tincture of iron, strychnine, and phenacetin will often be found useful means of treatment. Antistreptococcic serum is thought worthy of trial, also nuclein and silver. Abscesses should be opened as soon as they are apparent. Hysterectomy should rarely be practised. Pyosalpinx may be treated by abdominal or vaginal section, according to the indications.

3. **The Prevention of Puerperal Septicæmia.**—Berry Hart considers that in this disease the lymphatics are invaded by microbes conveyed on the fingers of the attendant or from the patients' uncleaned external genitals. Infection may also arise from preëxisting disease in the uterus or its appendages. Preventive measures consist: 1. In avoidance of infection by clean hands with or without gloves. 2. In cleansing the external genitals. 3. In avoiding laceration by skilful conduct during the labor. 4. In avoiding uterine manipulation to separate the placenta, which does not exclude manipulation during hæmorrhage. 5. In general hygienic care during pregnancy. A vaginal douche may be given at the end of labor, but subsequently cleansing should be accomplished with cotton moistened in bichloride solution. Puerperal infection is preventable, and should be prevented by conscientious individual effort.

4. **The Midwives Act, 1902.**—Cullingworth discusses this useful act which was intended to secure the better training of midwives and regulate their practice.

5. **A Criticism on the Midwives Act, 1902.**—Glover discusses this act from the standpoint of the general practitioner, and suggests that the requirements for the practising midwife should not be made too exacting.

6. **Some Impressions of Puerperal Septic Disease in Its More Severe Forms.**—Gordon thinks this disease is seen in its worst forms in a large isolation hospital, and his hospital experience has largely been with such cases. The women are usually very poor, have been attended by a midwife, and are not taken from their homes until their prospects for recovery have nearly or quite disappeared. Such patients are usually delirious, the abdomen is swollen, the uterus very large, cervix and perineum lacerated, and the uterine discharge fœtid. In the sapræmic cases, the disease being still local, recovery usually takes place. In

the septicæmic cases, with streptococcic invasion, even though the typhoid condition is present, there may be twenty per cent. of recoveries. In the septicæmic cases with infection from the colon bacillus, the infection occurs later than in the other forms and the result is usually fatal. The author believes in curetting in the severe cases with the sharp curette, and in irrigating and disinfecting the surface immediately afterward. Gloves are to be worn, and after the curettage an injection of antistreptococcic serum is to be made. Pelvic suppuration and septic thrombosis of the femoral vein have been frequent complications.

7. Prevention of Puerperal Fever in London Hospitals.—Gow mentions the following requirements for the accoucheur at Queen Charlotte's Hospital: 1. The finger nails must be short, no rings worn, the sleeves must be rolled up; 2, thorough washing of the hands with soap and water, and scrubbing with a nail brush; 3, hands must be rinsed in clean water, but not dried; 4, immerse hands in 1 to 1,000 bichloride solution for one minute, scrubbing with nail brush; 5, lubricate finger with vaseline immersed in 1 to 100 bichloride of mercury; 6, do not let examining hand touch anything before the examination; 7, after the examination wash hands thoroughly in soap and water. Treatment should be simply that which is comprehended in the expression—surgical asepsis.

8. Asepsis in the Rotunda Hospital, Dublin.—Tweedy describes this ancient maternity and the methods in vogue there. The attendant washes and scrubs his hands and wears gloves or finger stalls; instruments are boiled in soda solution. The vulva of the patient is cleansed and only four examinations are allowed during a labor. No douching is practised, the placenta is expressed after it has reached the vagina, a diaper moistened in bichloride is applied to the vulva, and an abdominal binder secured. Each bed has its own clothing and furniture. The patients are cleansed night and morning with all possible antiseptic precautions. All vessels used are sterilized. If symptoms of sepsis appear, examination is made, also a culture of the secretions, and a douche is given, also a purgative. If the symptoms persist, the douche is repeated the following day, secretion from the uterus is aspirated into a glass tube and a culture again made. The uterus is then douched with salt water, or hydrogen peroxide. If on the following day there is no improvement the patient is placed in an isolation ward and there receives special nursing and appropriate treatment. The mortality and morbidity have been reduced to an extreme limit.

9. Puerperal Fever and the Control of Midwives.—Paget observes that midwives are now subject to legal restrictions. The inspector acting under the medical officer of health has the following instructions: 1. To inspect the midwife's case book; 2, to inspect her antiseptic washes, lubricants, and instruments; 3, to report as to personal cleanliness; 4, to report as to the sanitary condition of her residence; 5, to see that she has washable dresses for use only in her prac-

tice; 6, to exercise educational influence on those who need improvement; 7, to carry out such correspondence concerning midwives as the county health officer may direct; 8, to report any case of malpractice, negligence, or misconduct as the health officer may direct.

10. Puerperal Septicæmia from a Public Health Aspect.—Williams states that statistics show that while this disease has almost disappeared from the lying-in hospitals it is as prevalent as ever in private practice. The author thinks this is largely due to the imperfections of midwives and prophesies great improvement from the influence of the new law regulating the practice of midwives.

11. The Pathology of Puerperal Fevers.—Foulerton observes that puerperal fever includes a number of forms of disease which differ in their pathology and their clinical features, hence no concise classification is possible. The processes involved in this disease are: 1. Infection of lacerations of the perineal tissues or of the vaginal wall with possible extension to the cavity of the uterus, that is, localized infection and toxæmia or these conditions and generalized infection in addition. 2. Primary infection of the contents of the uterus, or of the placental site, localized poisoning, or localized and then general infection. Ten different varieties of bacteria were found in a study of fifty-four cases of puerperal fever. Of these the streptococcus was by far the most frequent and most important. In many cases there was mixed infection. In the secondary infections the colon bacillus and the streptococcus pyogenes albus were most frequently found. Autoinfection is not frequent, but is possible as follows: 1. There may be infection by bacteria carried by the blood to the uterus from some focus of infection localized in a remote part of the body. 2. Infection may proceed from bacteria which were present before labor in the cervical canal or the upper part of the vagina. 3. Bacteria from the lower part of the vagina or the external tissues may be carried to the uterus by the examining finger or by instruments. Vaginal douching is usually, though not always, unnecessary, and so also is curettage. The latter is often harmful. In the absence of exact bacteriological diagnosis the safe rule is to treat every case of puerperal fever as probably of streptococcic origin.

12. The Blood in Puerperal Fever.—Emery sums up his study as follows: The patient may or may not be anæmic at term. If anæmic the hæmoglobin is reduced rather than the corpuscles. The leucocytes are increased, especially in the first pregnancies, the polynucleus being more numerous. If the puerperium is normal the leucocytes diminish soon after delivery and continue to do so for a fortnight. The red corpuscles and the hæmoglobin diminish for a day or two and then are regenerated. Should general septic infection occur, the leucocytes would increase, the hæmoglobin and red cells diminish, and the leucocytes would have the iodine reaction. Should abscess occur apart from general septicæmia the polynuclear leucocytes would show a marked increase.

and would give the iodine reaction. The hæmoglobin and red corpuscles would be affected slightly if at all.

13. An Epidemic of Puerperal Fever a Century Ago, and Its Surroundings.—Hellier writes of an epidemic at Leeds, from 1809 to 1812, recorded by William Hey. It was associated with a severe epidemic of erysipelas, but the connection of the two was not recognized. The treatment consisted of bleeding and purging, and with this treatment Hey states that all but three of his patients recovered. One of these was a consumptive, and one was not bled enough.

ANNALS OF SURGERY.

March, 1905.

1. The Diagnosis and Treatment of Fracture of the Carpal Scaphoid, and Dislocation of the Semilunar Bone,
By CODMAN and CHASE.
2. Fractures of the Tarsal Bones., By EISENDRATH.
3. Technics of Exposure of the Spinal Cord and Canal, Osteoplastic Resection, and Laminectomy,
By BICKHAM.
4. A Case of Cervical Rib, with Symptoms Resembling Subclavian Aneurysm, By MURPHY.

6. A Series of Cases of Intussusception in Childhood,
By WALLACE.
7. Intestinal Hernia, By CUMSTON.
8. The Relation of Mechanical Distention to the Etiology of Appendicitis, By VAN ZWALENBURG.

1. Fracture of the Carpal Scaphoid.—Codman and Chase draw the following conclusions as to the treatment of simple fracture of the scaphoid bone: 1. Cases which have not been treated or which have been treated as sprains, by a short period of fixation followed by massage, active and passive motion, seldom if ever have union of the fragments. 2. If the joint is kept fixed for a number of weeks immediately after the injury union may occur, but the functional result is not perfect, though better than in cases of non-union. 3. It is too late to obtain union if fixation is not attempted within a few weeks after the injury. 4. Excision of the proximal half of the broken scaphoid promises a better ultimate result than any other form of treatment. 5. In operation involving risk, a reasonable attempt should be made to obtain union by fixation, if the case is seen soon after the injury. 6. Operation should not be delayed many months, because secondary joint changes may occur and chronic arthritis result. 7. The advisability of operating in cases of long standing is doubtful, and must be decided by the amount of disability in each individual case.

2. Fractures of the Tarsal Bones.—Eisendrath gives as the points of greatest value in making the diagnosis of fractured tarsal bones, palpation of a fragment, pes valgus or varus traumaticus, the x ray examination, and the history of the case. *Treatment.*—1. In simple fractures without displacement. Immobilization at right angles, well padded removable cast. Massage on the third or fourth day. Cast should be worn eight weeks. 2. In simple fractures with displacement, if a frag-

ment impinges on the skin, make the fracture a compound one, with aseptic surroundings. Remove the fragment, if lateral. If behind the ankle and the tendo achillis is detached the latter should be sutured to the os calcis. If astragalus or os calcis is badly splintered, it should be removed. 3. In compound, crushing, and gunshot fractures, the same rules should be observed that apply elsewhere in the treatment of such injuries of the extremities. .

5. Intussusception in Children.—Fagge has operated in eighteen cases, and the advantages of operation are now generally recognized. Fourteen of the patients were under one year of age. In sixteen a tumor was felt through the abdominal wall or per rectum. Routine examination under an anæsthetic is always desirable in suspicious cases. All those cases in which the lesion had persisted less than forty-eight hours were reducible, reduction being facilitated by very early treatment. Ten of the intussusceptions were single and ileocæcal, one was single and enteric. Seven were double, three being colic ileocæcal, two ileocolic colic, two enteric ileocæcal. In one case there was probably a triple intussusception. In seventeen cases primary laparotomy was undertaken as quickly as possible, in one inflation had been twice tried without success. The incision was, as a rule, on the right of the middle line, its centre being at or below the level of the umbilicus. The combination of inflation with laparotomy is not approved. The intussusception can often be reduced by a finger in the rectum as high as the iliac colon, where it can be easily treated through the abdominal incision. Until the reduction reaches the ascending colon it is performed partly out of sight; the intussusception is then delivered from the abdomen. The escape of the intestines from the abdomen should be avoided as far as possible. When eventration has been compulsory the abdominal wound should be widely opened and the intestines returned, coil by coil.

Six patients died from shock and toxæmia within twenty hours after the operation; a seventh died on the fourth day, two more died on the twenty-third day, but only indirectly from intussusception. A number of the cases were gangrenous and offered no chance for recovery. There are remote as well as immediate risks from intussusception, and recovery from the acute illness may be more apparent than real. When the intussusception is irreducible, gangrene being present, resection is preferable to the formation of an artificial anus.

1. **Anthrax.**—(See our abstract of *British Medical Journal*, for March 11 and 18, 1905.)

2. **Surgical Shock.**—Mummery, in the first of his Hunterian lectures, tells us that the essential feature in the production of the condition known as surgical shock, is a steady fall in general blood pressure. This fall in blood pressure results from exhaustion or fatigue of the vasomotor centres. That it is not due to structural changes is evident from the fact that no lesions are found in persons dying from shock and that when recovery takes place it is complete. It is produced mainly in two ways: (1) By injury to important afferent nerve paths; and (2) by exposure or injury of the abdominal viscera. Shock and its causative conditions give rise to marked changes in the action of the heart. The pulse rate is only secondary to the blood pressure as a guide to the condition of the vasomotor mechanism. During the early stages of operations the pulse rate usually follows the blood pressure. In the later stages of severe operations, however, a fall in the blood pressure is usually accompanied by a rise in the pulse rate. The vasomotor centres are, of course, not the only ones affected—but the others, such as the cardiac or respiratory centres, are affected secondarily. In many cases of shock there is a marked toxic element present. Direct poisoning of the nerve centres, especially of the vasomotor centres by the toxins in the blood, is a factor of considerable importance in the production of exhaustion and paralysis of these centres. Collapse differs from shock mainly in the fact that the vasomotor centres are not exhausted—their function is only suspended. The symptoms in the two conditions are almost identical. Collapse is due to a sudden great fall in blood pressure, resulting from a severe hæmorrhage or from a great and sudden loss of circulating fluid, such as occurs in cholera; or from a sudden suspension of function or paralysis of the vasomotor centres, resulting from some violent afferent nerve impulse, as, for instance, a blow in the splanchnic area or upon the genital organs. In shock the condition develops gradually, whereas in collapse the symptoms come on suddenly or at least very rapidly. In shock treatment is very difficult and often unsatisfactory, since the nerve centres are exhausted. In collapse, however, treatment is apt to be more satisfactory and effective, since the cause is either a lack of circulating fluid which can be remedied, or a suspension of function of nerve centres which it is only necessary to set going again.

4. **Epilepsy.**—Turner defines epileptic equivalents as certain psychological states which to some degree take the place of epileptic seizures. The following characters may be accepted as sufficient reason for regarding psychological manifestations as epileptic equivalents: (1) The occurrence in the family history of similar or allied

conditions, interchangeable with forms of genuine epilepsy; (2) their association in the same person with forms of genuine epilepsy; and (3) the existence of definitely epileptic characteristics, such as sudden onset, transitory duration, and irregular periodicity. The interparoxysmal mental condition found in epileptics is not wholly a direct consequence of the seizures, but is an expression of the same hereditary degenerative constitution which gives rise to the convulsions. The close relation which exists between mental disability and facial expression is nowhere more readily seen than in cases of confirmed epilepsy. One of the commonest and at the same time most characteristic stigmata of degeneration is seen in facial asymmetry and deformity. Certain cellular cortical changes also occur which indicate defective cerebral development. The essential feature for the development of convulsions appears to be deprivation of arterial blood, coinciding with capillary and venous stasis, from cortical motor areas. The medicinal treatment of the convulsions forms only one item in the treatment of epilepsy. The most satisfactory management of the disease is that which is carried out in special institutions or under the care of a well trained and sensible nurse attendant. Epileptics suffer notoriously from lowered vitality and sluggish circulation in the extremities for which warm baths, spinal douches, and massage are important remedial agents. In the treatment of epilepsy there has ever to be kept in mind the persistent character of the malady and the tendency towards mental deterioration.

5. Industrial Anthrax (*Milroy Lectures, II*),
By T. M. LEGGE.

2. **Puerperal Infection.**—Lea states that the frequency of severe puerperal infection has shown little diminution during the last forty years in Great Britain, except in lying-in hospitals, where the mortality has been reduced to a minimum. Puerperal sepsis still causes over 40 per cent. of all deaths in child birth, and its death rate is 2 per 1,000. It occurs mainly among women confined at home and attended by midwives. Overcrowding, climate, and even zymotic diseases, such as diphtheria and scarlet fever, have but little to do with its production. And there is still far too much sepsis among patients of the better class attended by physicians. The gravity of instrumental or manual interference cannot be too strongly insisted upon. The essential point is surgical cleanliness. The morbidity, that is, the proportion of cases in which a rise of temperature takes place, varies from 10 to 15 per cent. in even

the best maternity hospitals. Puerperal fever is a wound infection, nearly always the result of the introduction of organisms from without. The conditions during and after delivery are such that it is surprising that infection does not take place in every instance. Many organisms may produce the disease. *Streptococcus pyogenes* is the most frequent; many varieties exist, and exhibit all degrees of virulence. Streptococcal invasion of the uterus is often characterized by gray membranous exudation over the cervix; the lochia are usually profuse, hæmorrhagic, and not offensive. In severe cases they may be suppressed. *Staphylococcus pyogenes*, *albus* and *aureus*, are usually only saprophytic, but occasionally they may cause severe or even fatal infection. The colon bacillus is a frequent cause of infection. The infection is often superficial and characterized by very offensive lochia, often becoming purulent. Association with streptococci increases the virulence of the colon bacillus. Other specific organisms occasionally met with are the diphtheria bacillus, the typhoid bacillus, and the tetanus bacillus. The saprophytic bacteria of the vagina are responsible for many cases of infection; they are anaerobic and usually non-pathogenic. The clinical course of puerperal infection depends on many factors; among them are: (1) The period at which infection occurs; (2) the site of infection; (3) the type of organism and its virulence; (4) the local conditions present in the uterus; and (5) the resisting power of the individual. Putrid infection of the uterus may occur—(a) as an infection of the amniotic fluid, commencing before delivery; (b) as an infection of the placenta, especially after abortion; (c) as an infection of the decidua and blood clot *in utero* after delivery; (d) as gaseous septicæmia; large quantities of gas developing in the uterus; (e) as an abscess of the uterus or infection of a myoma; and (f) as gangrene of the uterus or dissecting metritis. Autogenous infection may occur as absorptive fever from decomposition of clots, decidua, or placenta. Gonorrhœa at the time of delivery may cause an autogenous infection. The early symptoms are few but definite: 1. The temperature usually rises within forty-eight hours; this is slight at first, but becomes marked on the third or fourth day and is often accompanied by a chill. Fever after the fifth day points to a post partum infection. 2. The pulse rate is early increased and out of proportion to the degree of pyrexia. 3. Delayed involution of the uterus is characteristic of infection of the uterine cavity, and is often accompanied by tenderness. The cervix is soft and patulous. 4. The lochial changes are not uniform, and should be investigated bacteriologically always. The writer discusses the various modes of treatment and the indications for the same. His conclusions regarding the use of antistreptococcal serum are as follows: 1. The serum is innocuous if carefully prepared and injected with due precaution. 2. It must be administered early in the disease and in large doses—20 c.c. twice or thrice in twenty-four hours in severe cases. 3. If administered early and in large doses definite improvement is observed in a considerable proportion of cases. 4.

All statistics are valueless unless accompanied by bacteriological details.

3. **Lead as an Abortifacient.**—Hall reports a series of thirty cases of lead poisoning resulting from the use of lead to produce abortion. This practice prevails in the Midland districts of England, and is gradually increasing. The drug is usually taken in the form of patented pills—for "regulating" the monthly periods, etc. The author has purchased and analyzed several varieties of these pills, and finds that they all contain small quantities of lead. All of his patients were women of child-bearing age, usually married, and mothers of families. Of the first 18 patients, 11 did miscarry, one was pregnant, five admitted delayed menstruation, while only one denied any menstrual trouble. More than half the patients admitted having taken an abortifacient.

5. **Anthrax.**—Legge, in his second Milroy lecture, discusses the treatment of anthrax. Until recently it has been merely expectant or consisted in cauterization or other allied treatment of the local pustule. But a serum derived from an immunized animal is coming more and more into use. As spontaneous cures are frequent in external anthrax, the relative value of the three methods of cure must be considered—i. e., as to the amount of scarring, time required for treatment, etc. The general mortality is 25 per cent. Good results can be obtained by excision if it is practised early. The claims for the serum treatment are as follows: 1. It is innocuous even in large doses. 2. It can be well borne even when introduced into the veins. 3. No case taken in an early stage, or of moderate severity, is fatal if treated with the serum. 4. Some apparently hopeless cases are saved by the use of the serum. 5. When injected into the veins the serum quickly arrests the extension of the œdematous process which often causes death by suffocation. 6. It reduces to a minimum the destruction of tissue. 7. In some situations (eyelid) the serum must not be used. 8. Patients treated with the serum appear to become convalescent in a few hours. 9. In internal anthrax, where it is administered intravenously, it is the only treatment which can hold out any hope. The serum is prepared by Professor Scavo, of Siena, Italy, and is known by his name. It is obtained from asses which have been immunized against the disease.

 4. The Therapeutic Value of Relaxing Climates, By WILLIAMS.
 5. On Addison's Disease, with Two Cases, and Also a Case Which Presented the Symptoms of Disease of the Suprarenal Capsules, By CONDER.
1. **Chronic Suppuration in the Frontal Sinus.**—Turner admits that there is no single method

of procedure applicable to all cases of this disease. If the sinus is a small one and inspection of it through the aperture made in the anterior wall has been thorough, and if no ethmoidal disease co-exists, opening and draining may suffice. Communication with the nose by means of a drainage tube must be kept up for a long period. In all other cases the sinus should be obliterated. This permits thorough inspection, access to the ethmoidal cells, and free communication with the nose. The bridge of the nose need not be preserved if the sinus is shallow and the supraorbital region is not prominent. Whatever radical procedure is adopted the ascending process of the superior maxilla should be removed to facilitate access to the ethmoid labyrinth and nasal cavity. The author feels the desirability of collective investigation into the results of surgical interference upon the frontal sinus and possibly upon the antrum also.

4. The Therapeutic Value of Relaxing Climate.—Williams affirms that the attitude of the majority of physicians toward climatic treatment is that of indifference. This is partly due to the lack of opportunity to become familiar with climatotherapy. Change of air is often recommended, but in a very vague manner. Besides pure air, moisture, sunshine, and exposure must always be thought of. The bracing climate is most useful for those who are in moderately good health, its elements, including high altitude, dryness, and rarefaction of the atmosphere, free exposure to sun and wind, and moderate rainfall. In the relaxing climate, which has no charms for the robust, there are moderate elevation, moderate exposure to wind, full exposure to sun, and high humidity with equability of temperature. This is the climate which is desirable for sufferers with chronic pulmonary disease, chronic renal disease, and chronic nervous disease. In the chronic pulmonary diseases sedative measures are more frequently indicated than stimulating ones. A relaxing climate is therefore very often the most suitable. Emphysema is much benefited by a moist atmosphere, and may serve as the type of pulmonary diseases, which are best treated by a relaxing climate. For the chronic kidney diseases, especially intestinal nephritis, the climatic essentials are warmth and equability. A bracing climate constricts the cutaneous vessels and raises the blood pressure, while a relaxing climate reduces it. For these diseases, therefore, Madeira, the Canaries, and many places in France and the British Isles are eminently suitable. In chronic heart disease also one must remember the danger arising from too bracing a climate, with heightened blood pressure, mental exhilaration, and improved functioning of the entire organism. In the degenerative processes of the nervous system in which the most that can be done is to retard the morbid process, the relaxing climate is the only safe medium; a bracing climate, though more agreeable will hasten the fatal issue. With the climatic treatment, such therapeutic aids as baths and waters go hand in hand. A locality should therefore be chosen, if possible, in which all these desiderata can be combined.

5. A Case for Diagnosis, By BELL.

2. Certain Problems of the Nervous System.—Mills finds that all experimenters agree that no functional union can take place between the central ends of two nerves. Bethe believes that functional union of the peripheral ends of two limb nerves has been demonstrated in puppies. Langley and Anderson could not get such union in rabbits and cats. If the central end of a limb nerve joins two peripheral nerves, stimulation of one peripheral nerve, after severance of the joined nerves from the central nervous system may cause contraction of the muscles innervated by the other. This is an axon reflex set up in fibres from the central end, one branch joining one peripheral nerve, and the other branch joining the other. If one peripheral nerve consists of afferent fibres an axon reflex may still be produced by stimulating it. This supports the view that regeneration takes place by downgrowth of axis cylinders. Nerves may be lengthened by joining them with a corresponding nerve of the opposite side. The phrenic nerve can unite functionally with the cervical sympathetic, and the cervical sympathetic with the recurrent laryngeal. The functional result will be that which is proper to the nerve of final distribution. The fibres of the sympathetic in the neck central cannot, when the ganglion is removed, make functional connection with those beyond the ganglion; preganglionic fibres cannot connect with postganglionic fibres. Afferent fibres cannot unite with efferent and give motor effects, that is, they cannot really coalesce with efferent fibres. Whether the regeneration taking place when fibres of the same class are united is due to coalescence or to downgrowth is still a matter of dispute.

Letters to the Editor.

AN OPERATION FOR PHIMOSIS.

MERIDIAN, MISS., March 27, 1905.

To the Editor,

Sir: I have an operation to report performed according to my method of circumcision. The operation was done by Dr. de Gaffenried, of this city, assisted by myself, and done according to my method. After sterilizing the instruments, etc., an incision was made with scissors on the dorsum through the skin and mucous membrane as far up as possible. These two flaps were held back and the prepuce was stitched all around behind the corona and as high up as they could be inserted, using the smallest size continuous catgut suture, the frenum being skipped, the last stitch coming out opposite the first. The operation was done in fifteen minutes. The suture first having been inserted, then all the prepuce in front of it was trimmed or cut off with scissors as close to the suture as possible. Then the operation was ended. There was good coaptation, with very little hæmorrhage. It is now five days since the operation. The wound is nearly all healed by first intention. There is no pus and the little suture is entirely absorbed. The advantages of this method are: 1. The continuous small sized catgut suture is inserted before there is any cutting done (except the dorsal cut), making it an easier job to insert the sutures, as in the old method the field for insertion of the sutures is obscured by the blood, making it troublesome to insert the sutures. In my plan there is very little bleeding, and if there is bleeding, the sutures are already inserted; hence the bleeding does not interfere with the suturing. The use of the smallest size catgut suture that will hold causes less irritation and helps union by first intention. This is a little thing, but little things count. J. M. WHITE.

Proceedings of Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of February 22, 1905.

The President, Dr. JAMES M. ANDERS, in the chair.

The Pasteur Treatment for Rabies Administered at the Patient's Home.—Dr. MYER SOLIS COHEN reported the following case: A man and his son were bitten by a dog whose medulla and plexiform ganglia showed the changes diagnostic of rabies. They were given the Pasteur treatment at their homes, the virus being mailed by special delivery each day by the Pasteur Institute of the Department of Health of New York city. On its arrival the virus was put on ice and as soon after as practicable was injected with aseptic precautions into the subcutaneous tissue of the abdomen. The patients' bowels were kept open and alcoholic excesses were avoided. There was no constitutional disturbance or any interruption of the daily work.

On but two occasions did the treatment cause a local reaction, which, however, responded to antiseptic measures. Two weeks after the cessation of all treatment no symptoms of rabies had developed. The patients consequently were considered out of danger.

Dr. COHEN concluded that a person when bitten by a rabid dog need not necessarily go to a Pasteur Institute for treatment, but, if within a day's journey of one, might be supplied daily by mail with the virus, which could then be injected by the family physician, with probable success.

Dr. ERNEST LAPLACE referred to his privilege of working with Pasteur in 1885 and 1886 in his experiments which had resulted in an absolutely preventive treatment of hydrophobia. Pasteur never made a diagnosis of hydrophobia unless a piece of the brain or spinal cord of the dog was injected into rabbits and they died of hydrophobia. Dr. Laplace did not advocate the adoption of this method, but believed that for the scientific value of the treatment it was not well to be satisfied without this inoculation. Although the germ of hydrophobia had not been found, Dr. Laplace believed that the treatment was based upon a scientific foundation. That the poison existed was undeniable, for it could be produced and reproduced, attenuated, and made more and more virulent at will; and more could be done with this poison than with any other, except that of anthrax. Pasteur's idea was to produce in a patient with dog hydrophobia, which required three weeks for development, a tolerance of the rabbit hydrophobia, which was more virulent and took only ten days to develop. The pains alluded to in Dr. Cohen's case he thought due to local causes. If treatment could be carried out at home, he regarded it as a step of great worth to medicine in general. The moral effect upon a patient leaving home in a desperate rush for treatment he considered very bad.

Dr. WILLIAM M. ANGENY referred to a person bitten by a supposedly rabid dog who was sent to New York for the first two days' treatment, and after that the virus was sent to Dr. Angeny for use.

Dr. G. MORTON ILLMAN thought it strange that there should not be an admission of the diagnosis of hydrophobia, since the condition is proved by inoculation and was rapidly becoming associated with a definite pathology. In human beings there were distinct changes in the ganglion cells and in the medulla. With their complete Board of Health, he thought Philadelphia should have a laboratory in which this treatment could be carried out.

Dr. COHEN said that in the question of whether or not a dog had rabies, if the head only was taken to the pathologist of the Live Stock Sanitary Board of Pennsylvania, a report would be given on it.

Surgical Intervention in Cases of General Peritonitis from Typhoid Perforation, and from Acute Gonococcus Infection.—Dr. JOSEPH PRICE said that the profession had been slow in accepting the overwhelming evidence of operative and clinical facts. A few of the early surgical obstructionists, however, were now the most aggressive and persistent advocates of early surgical intervention in abdominal traumatism and pathology. With the present precise knowledge of pathology and diagnosis, he believed there was no excuse for delay in operation. Surgical intervention for peritonitis and

perforating ulcers was suggested during the seventeenth, eighteenth and nineteenth centuries, but nothing of a positive nature was done until about 1878. Embolism of large and small mesenteric vessels he believed had not yet received deserved attention. Any variety of peritonitis or infection should be anticipated surgically. From a long experience he believed that about all the sufferers from perforations in and about all the viscera in the peritoneal cavity, typhoid, suppurative, gall bladder, gastric, and duodenal perforations should be saved. The possibility of peritonitis remaining local or circumscribed by adhesions should not be considered if a diagnosis of perforation had been made. Firm, pure silk he regarded as the best suture material and the interrupted sutures as giving the best results with less risk of strangulation. If the margins of the ulcer were ragged, they should be trimmed. A resection was unjustifiable. The irrigation should be a thorough cleansing of the entire surface with sterilized water. It was his impression that irrigation with hot normal salt solution was harmful, causing irritation. Curetting or wiping dirty points with gauze was followed by good results. The gauze pack, as so commonly and recklessly used, he regarded as a dangerous thing. Two typical cases were cited and the plea was made for early diagnosis, early surgery, and more thorough toilets to arrest peritonitis and sepsis.

Dr. ERNEST LAPLACE said that cases of peritonitis proved fatal because of their coming too late to the surgeon. This he thought was more often the fault of the physician than of the patient. Two distinct problems in Dr. Price's paper, he said, were peritonitis as produced by perforating typhoid ulcer, and diffuse peritonitis from other causes. An important point of difference between the two was that when a typhoid fever ulcer perforated, the contents of the intestines that flow into the peritoneal cavity were largely harmless at the time, as it required a little while for the germs to become pathogenic. If such a case ended in recovery, the poisoning was local. It was quite a different thing to treat a foul peritonitis resulting from a gangrenous appendix or from the rupture of an appendicular abscess that had gradually leaked into the abdominal cavity.

The abscess cavity in particular and the peritoneal cavity in general, he believed were best cleaned out with sterile water. The much vaunted saline solution, he thought, was objectionable on account of its irritating effect. The cleansing of the abdominal cavity should be continued as long as it was possible without detriment to the patient, and to effect this he carried out a plan of repeated irrigation.

Temperature and pulse records, while valuable with reference to shock, gave no indication of the necessity for an operation. The decision should depend upon the general appearance of the patient. In washing out the abdominal cavity he avoided the use of gauze, using rather the smooth surface of a glove or the bare hand. While iodoform gauze was a great power for good in some wounds, in some it caused increased inflammation. If used at all it should cover only the spot that was the seat of the abscess, and should be separated from the rest of the cavity by the plain gauze.

Dr. JOHN H. GIBBON did not believe the diagnosis of typhoid perforation easy, and he regarded it as a

great mistake to wait for the typical symptoms of perforation before the surgeon was called in. The most valuable symptoms to the surgeon, in his opinion, were localized pain and rigidity coming on suddenly. He agreed with Dr. Price that resection was hazardous. Anchoring the bowel, surrounding it with coffee dams of gauze, he believed was the best method. The element of time he regarded as of the utmost importance in these operations. In localized peritonitis thorough drainage was better than thorough irrigation, but generalized peritonitis demanded complete irrigation. Admitting that salt solution might give pain when applied to the peritonæum, he yet believed that it did good.

Dr. B. F. BAER's experience with salt solution did not agree with that of Dr. Laplace. He had used it for the last few years, and believed it nourished the patient by filling the blood vessels. There was less probability of adhesions, and the skin was in a better condition on account of the effect of the salt solution upon the kidneys.

Dr. LAPLACE explained that he had said he believed salt solution would irritate in general peritonitis where from the washing there could only be expected a cleansing effect and where the amount of the solution was insufficient to prove an antiseptic.

Dr. EDMUND W. HOLMES thought surgeons should agree that the four symptoms of pain, localized tenderness, abdominal rigidity, and some interference with respiratory action were indications for operative interference.

Dr. R. P. McREYNOLDS thought the diagnosis in typhoid perforation particularly difficult. In general peritonitis from gonorrhœal infection he saw no reason for operating in the acute stage. The temperature came down to normal if the patients were kept in bed, given hot douches, and treated by the expectant method. After this the purulent tubes might be removed and the abdomen closed without drainage.

Dr. PRICE said that no progress in medicine had pleased him more than that of the modern clinician in the question of diagnosis. It was his experience that often the rural practitioner would make a more refined and accurate diagnosis than he personally was willing to make. In the packing of gauze, too often there resulted bowel pressure. It should be placed not too low down, and not packed upon viscera paralyzed by peritonitis and overdistention. The cases of peritonitis which he feared the most were those with enormous distention. With reference to waiting for recovery from collapse or for reaction, practised by early operators, Dr. Price believed surgery to be a very good treatment for shock.

Book Notices.

Handbuch der Tropenkrankheiten. Herausgegeben von Dr. CARL MENSE, Kassel. Erster Band, mit 124 Abbildungen im Text und auf 9 Tafeln. Leipzig: Johann Ambrosius Barth, 1905. Pp. xii+354. (12 marks.)

The last few years have witnessed a remarkable renewal of interest in the diseases of tropical climates, and the revival can hardly have failed to

facilitate medical administration in our new tropical possessions. Indeed, our own medical men serving in Cuba and in the Philippines have contributed not a little to the common stock of knowledge of such diseases. In this handbook Dr. Mense has had the collaboration of Baelz, of Tokyo; Bassett-Smith, of Haslar; Van Brero, of Lawang; Van der Burg, of Utrecht; Calmette, of Lille; Carroll, of Washington; Eysell, of Kassel; Leishman, of London; Looss, of Cairo; MacCallum, of Baltimore; Martin, of Diessen; Plehn, of Berlin; Pösch, of Vienna; Rho, of Naples; Ruge, of Kiel; Rumpf, of Bonn; Sander, of Berlin; Van der Scheer, of The Hague; Stickler, of Giessen; and Ziemann, of Charlottenburg. It will be seen therefore that the book may well be called an international work.

The first article, by Plehn, is on tropical diseases of the skin. Diseases occasioned by worms and the *Arthropoda* are then treated of by Looss. The next article, on the nervous and mental diseases of the tropics, is by Van Brero. The varieties of vegetable poisoning are described by Rho, and those of animal poisoning by Calmette. All these articles are of the condensed cyclopædic character, and they are freely and very effectively illustrated. The volume gives great promise that the completed work will be a noteworthy addition to the literature of tropical diseases.

Pathologische Physiologie. Ein Lehrbuch für Studierende und Aerzte. Von Dr. RUDOLF KREHL, O. Professor und Direktor der medizinischen Klinik in Strassburg. Dritte neu bearbeitete Auflage. Pp. xvi-620. Leipzig: F. C. W. Vogel, 1904. (Price, 15 M.)

The title of this volume involves a contradiction to established definitions of a few years ago, and affords some indication of the rapid progress which is being made along important lines. Pathological physiology is indeed a misnomer if the scope of physiology is limited to a consideration of the normal functions of the body, but this is no longer admissible. One of the distinguishing and attractive features of Landois's *Physiology* of a generation ago was the attention devoted to the changes in function produced by disease. Other writers on general physiology have since followed more or less the example of Landois in this respect, but it has remained for Professor Krehl to elevate pathological physiology to the rank of a distinct and separate subject. That there was need of such a treatise is sufficiently shown by this third edition of his scholarly work. In it will be found much interesting material which has hitherto been available only from the most scattered sources. Of special value are the chapters on the blood, including hemolysis; recent problems of infection and immunity; nutrition, and metabolism. In them the reader will find a clear guide to many of the intricate developments in modern experimental medicine which promise important practical results in the near future. The value of the text is materially increased by a complete index and by the wealth of references to recent literature accompanying it.

Outlines of Physiological Chemistry. By S. P. BEEBE, Ph. D., Physiological Chemist to the

Huntington Fund for Cancer Research, and B. H. BUXTON, M. D., Professor of Experimental Pathology, Cornell Medical College. New York: The Macmillan Company; London: Macmillan & Co., Limited, 1904. Pp. vii-195. (\$1.50.)

The increasing attention which has been paid to the study of physiological chemistry has called forth several valuable manuals on the subject during a recent period, but none that we have thus far examined makes so successful an attempt to deal with the theoretical side of the many questions involved in this study as does the little work before us. The theory of solutions is studied in the opening chapter, and a terse but succinct account is given of the phenomena of ionization. The nature of the reactions in chemico-physiological processes is explained throughout, and the work closes with a valuable chapter on disease and immunity, which is explanatory of the actions of serums. All the important discoveries of modern chemical research which are utilized in the teaching of physiological chemistry are embodied in this handy-sized textbook, which should commend itself strongly to teachers.

A Manual of Personal Hygiene. Proper Living Upon a Physiological Basis. By AMERICAN AUTHORS. Edited by WALTER L. PYLE, A. M., M. D., Assistant Surgeon to the Wills Eye Hospital, Philadelphia; Secretary of the Section on Ophthalmology, American Medical Association, etc. Contributors: D. H. BERGEY, M. D.; J. W. COURTNEY, M. D.; GEORGE HOWARD FOX, M. D.; E. FLETCHER INGALS, M. D.; WALTER L. PYLE, M. D.; B. ALEXANDER RANDALL, M. D.; G. N. STEWART, M. D. (Edin.); and CHARLES G. STOCKTON, M. D. Second Edition, Revised and Enlarged. Philadelphia: W. B. Saunders & Co., 1904. Pp. xiv-441. (Price, \$1.50 net.)

In the second edition this useful book has been augmented by an illustrated section on home gymnastics, a chapter on domestic hygiene, and an appendix explaining the simpler methods of massage, bathing, and first aid. It is a book that the physician may recommend for his patient.

Miscellany.

The Present Position of the Treatment for Carcinoma of the Rectum.—Mummery, in the *Practitioner*, for November, 1904, in referring to the present practice states that excision is performed, as a rule, only when the growth is small, is easily reached from the anus, and is not fixed to surrounding parts. This limits the operation to less than 10 per cent. of all cases of cancer of the rectum.

The percentage of suitable cases is smaller than in other forms of cancer, because the disease is seldom detected in its early stage. Too often the piles or fistula which may complicate the disease is thought to be the only difficulty, and too often a careful digital examination is not made.

The operation also is a difficult one, and the mortality has been high, sepsis being the most cause of a fatal result.

The reduction of the mortality from the opera-

tion must be aimed at, and this must come by improvement of the technics.

With regard to recurrence, if the diseased tissue has been thoroughly removed the statistics are favorable. The glands are not involved early, and metastatic deposits occur late, if at all. The unfavorable features of the operation and its consequences have been overdrawn and the percentage of those who recover and who lose control of the faces is not more than 10. Even should incontinence occur it can be overcome if necessary by the performance of colotomy, which also leads to far less annoying consequences than have usually been depicted. Colotomy is not to be recommended as a palliative measure in the treatment of cancer, but it is sometimes imperative when complete obstruction of the rectum threatens. The possibility of cancer high up in the rectum, or in the sigmoid flexure, must not be overlooked, and it can best be diagnosed by the aid of the electric sigmoidoscope. A growth in this location is best removed by the abdominal or the abdominoperineal route.

If the lowest portion of the growth is not more than two inches from the anus the perineal operation is the most desirable. A portion or all of the coccyx may be removed to give sufficient space. A preliminary colotomy may be required especially if the sphincters must be removed.

Fixation of the tumor need not prevent its removal if it is only of inflammatory origin.

In inoperable cases the tenesmus may often be relieved by castor oil or salts. If the hæmorrhage is profuse the ulcerated tissue may be curetted away, or the cautery may be used.

Irrigation of the rectum with 5 volumes per cent. of cold peroxide of hydrogen with chlorine water, may also be practised. The diet should be fluid, as far as possible.

Internally one may use perchloride of iron or potassium iodide, salol, creosote, phenacetin, and a variety of other drugs before resorting to morphine.

Prescribing Pharmacists and Dispensing Physicians.—At the March meeting of the Kings County Pharmaceutical Society, Dr. J. H. Droge, of Brooklyn, presented an interesting paper on *The Pharmacist and the Physician*, in which he dwelt on some of the sins of the pharmacist in his relations with physicians and of the shortcomings of medical men. Originally, said Dr. Droge, the pharmacist and the physician were one; but gradually a separation was brought about and we now have two distinct recognized professions. By legislation and through colleges with the various State boards of pharmacy, the standing and efficiency of both professions were being gradually raised. A large number of physicians wrote their prescriptions, depending upon the skill of the pharmacist properly to compound them. This should be so, as the doctor's time could be well occupied by the study and cure of disease, and not by compounding and dispensing his own remedies. But, asked Dr. Droge, What had become of our old time, reliable, competent manufacturing retail pharmacists and dispensers, and what were the causes that had driven them away from their noble profession? How many retail

pharmacists to-day prepared their tinctures, pills, ointments, elixirs, extracts, etc.? All these preparations were sold by the manufacturers and bought by the pharmacists, thereby saving time and money.

The manufacturers controlled the supply of drugs which they bought at the lowest prices, but the drugs were not always of the highest grade. By the use of machinery he could turn out better looking products, such as tablets, pills, tinctures, and ointments. No hand made pill could compare in shape, uniformity, and appearance with those made by the leading pill makers. Few retail pharmacists could make their own preparations as cheaply as they could buy them ready made, but it was a question whether they got the best grades of chemicals and drugs in these preparations and whether the physician obtained the desired result from his prescriptions.

Referring to the increasing competition which the pharmacist is compelled to meet on all sides, Dr. Droge said he was forced into giving a certain amount of medical advice and into counter prescribing whether he wished to or not. He was constantly called upon to treat emergency cases, to dress wounds and sores, treat coughs, colds, rheumatism, headaches, or other ailments, and the customer was willing to pay double the price for the drugs, in order to save a doctor's fees. There was no question that in many cases counter prescribing was overdone. The pharmacist had no legal right to make a diagnosis and to treat diseases; his function was to compound prescriptions and to sell drugs, not to treat illness. Dr. Droge said he considered it wrong to allow a person to suffer and perhaps die from want of temporary aid by a pharmacist in the absence of a physician and the courts would uphold the pharmacist in such cases. Yet the pharmacist did not only given temporary relief for emergency treatment, but he continued the treatment from day to day and from week to week. In many cases the practice obtained this way was much more lucrative than that of his neighbor, the physician, and he made more money than he would in adhering strictly to compounding and selling drugs. It was not likely that he would give up this part of his income for sentimental reasons only. Consequently the physician would endeavor to prevent his prescriptions being taken to a drug store where these objectionable practices prevailed, or he would dispense his own drugs. He also must earn his living and get it, in spite of all drawbacks; such as the prescribing druggist, the advertiser, the quack, and the manufacturer of ready made remedies. He would oppose all such in an endeavor to hold that which he considered rightfully his own. Medicine was a profession and the advice of a physician was given for the welfare of his patient and not for the sole benefit of financial gain on the part of the physician. The constant aim of the medical profession was to alleviate suffering, to reduce the amount of sickness, and by sanitary methods to prevent the causes and spread of diseases. What other profession or class of men constantly endeavored to take away from themselves the source of livelihood? Did they not try to prevent that from

which they made a living—namely, disease? And still the physician had to contend with a great many unscrupulous people who were constantly aiming to make money regardless of whom their treatment might injure. Whether the patient needed the goods or not, the quack or the charlatan, in his convincing manner, misled suffering humanity into buying his goods and the result in the majority of cases was injurious to the health of the patient.

Every day new remedies were put before the public by well worded advertisements, not alone by means of posters, circulars, and the public press, but, he was sorry to say, through the medical, religious, and pharmaceutical press. Innumerable sample packages or powders, pills, tablets, etc., were mailed to clergymen, school teachers, and prominent persons exploiting the wonderful effects of their remedies, endorsed in many cases by physicians!

One gross injustice to the doctor and a dangerous procedure by some unscrupulous druggists was the substitution of other articles than those ordered. High priced drugs of certain known strength were replaced by cheaper ones of variable quality, and thus the calculations of the physiological action were upset. The doctor failing to obtain the desired effect from the drug prescribed lost confidence in the drugs or druggist and resorted to dispensing or depended largely upon suggestion and hygiene. How many physicians knew that paregoric was often made from benzoic acid obtained from urine? Two samples could rarely be found to resemble each other in medicinal properties and therapeutic strength.

Three fourths of the salicylic acid sold was made from coal tar and not from true oil of wintergreen, often producing serious gastrointestinal inflammation. Cheap preparations of ipecac were inert. Sweet spirit of nitre, syrup of iron iodide, tincture of nux vomica, belladonna, digitalis, ammonium carbonate, etc., were all injured by age, yet they continued to be dispensed until the supply gave out.

Any number of preparations could be mentioned which required careful watching on the part of the conscientious druggist. The doctor who practised medicine blindly, and paid no attention to the important factor of pure drugs, was simply gambling on the case. With the physician quality was considered of primary importance, price a secondary matter.

A very unprofessional and injurious practice of a few druggists and doctors was the prescribing and dispensing of secret preparations by number or name known only to the pharmacist and the physician. The patient was thereby compelled to have the prescription compounded at that particular drug store, the chances being that the patient paid an extra high price for his drugs. Who knew that the doctor was not also a financial gainer by the transaction?

Dr. Droge made a plea for an extension of pharmaceutical teaching in the medical colleges, saying he did not think it out of place to mention this subject which to his mind was of great importance to both professions. Every medical student should be compelled to take a practical course in

pharmacy. He should know how to write a prescription intelligently, giving proper dosage and avoiding incompatibilities, and be familiar with the appearance of drugs and mixtures prescribed. During his own brief experience as a pharmacist he said he had the opportunity of learning the merits of properly prepared prescriptions. The scheme introduced by the Kings County Pharmaceutical Society some time ago of presenting to the physician samples of preparations compounded according to the National Formulary and the United States Pharmacopœia was, he thought, a very good one.

A great mistake some physicians made was to tell the patient to buy ten grains of antipyrine or five grains of quinine or some other drug, or some proprietary preparation, whereas if he would write a prescription for the patient, it would be of advantage to himself and the pharmacist from a financial point of view and oftentimes prevent serious results to the patient at a future date because of his taking the drug without consulting the doctor, possibly when it was not indicated.

Official News.

Public Health and Marine Hospital Service:

List of Changes of Stations and Duties of Commissioned and Non-Commissioned Officers of the Public Health and Marine Hospital Service for the seven days ending March 29, 1905:

- BAILHACHE, PRESTON H., Surgeon. Reassigned to duty at Stapleton, N. Y., effective March 8th.
- BLUE, RUPERT, Passed Assistant Surgeon. Relieved from duty at the Plague Laboratory, San Francisco, Cal., and directed to proceed to Norfolk, Va., and assume command of the service.
- BROWN, B. W., Passed Assistant Surgeon. Upon being relieved by Surgeon J. B. Stoner, to proceed to Louisville, Ky., and assume command of the service, relieving Passed Assistant Surgeon G. B. Young.
- COFER, L. E., Passed Assistant Surgeon. Reassigned as Chief Quarantine Officer of the Territory of Hawaii, effective December 1, 1904.
- CORPUT, G. M., Passed Assistant Surgeon. Upon being relieved by Passed Assistant Surgeon M. K. Gwyn, to proceed to New Orleans, La., and report to Medical Officer in Command for duty and assignment to quarters.
- CURRIE, D. H., Passed Assistant Surgeon. Directed to assume temporary charge of the Plague Laboratory, San Francisco, Cal.
- EAGER, J. M., Passed Assistant Surgeon. Upon being relieved by Assistant Surgeon A. J. McLaughlin, to proceed to Washington, D. C., and report at the Bureau for duty. March 24, 1905.
- FOSTER, M. H., Passed Assistant Surgeon. Detailed as inspector of unseviceable property at San Diego Quarantine Station.
- GRUBBS, S. B., Passed Assistant Surgeon. Upon being relieved by Passed Assistant Surgeon C. W. Wille, to proceed to Chicago, Ill., and report to the Medical Officer in command for duty and assignment to quarters.
- GWYN, M. K., Passed Assistant Surgeon. Upon expiration of leave of absence, to proceed to South Atlantic Quarantine Station and assume command of the service, relieving Passed Assistant Surgeon G. M. Corput.
- HERTY, F. J., Pharmacist. Granted leave of absence for four days from March 8, 1905, on account of sickness.
- KING, W. W., Passed Assistant Surgeon. Granted one day's leave, March 18, 1905, under paragraph 189 of the regulations.

KORN, W. A., Passed Assistant Surgeon. Granted leave of absence for seven days from March 29th.

LUMSDEN, L. L., Passed Assistant Surgeon. To proceed to Perth Amboy, N. J., for duty during absence of Passed Assistant Surgeon W. A. Korn.

McKAY, MALCOLM, Pharmacist. To report, April 3, 1905, to chairman of board for physical examination to determine his fitness for promotion to the grade of pharmacist of the first class.

McLARTY, A. A., Acting Assistant Surgeon. Granted leave of absence for thirty days from April 1st.

McLAUGHLIN, A. J., Assistant Surgeon. Relieved from duty in the Bureau, and directed to proceed to Naples, Italy, for duty in the office of the American Consul, relieving Passed Assistant Surgeon J. M. Eager. March 25, 1905.

STONER, G. W., Surgeon. Reassigned to duty in the Immigration Service, Ellis Island, N. Y., effective March 8th.

STONER, J. B., Surgeon. Relieved from duty at Norfolk, Va., and directed to proceed to Evansville, Ind., and assume command of the service, relieving Passed Assistant Surgeon B. W. Brown.

WILE, C. W., Passed Assistant Surgeon. Upon being relieved by Surgeon L. L. Williams, to proceed to Gulf Quarantine Station and assume command of the service, relieving Passed Assistant Surgeon S. B. Grubbs.

WILLIAMS, L. L., Assistant Surgeon-General. Relieved from duty in the Bureau, and directed to proceed to Baltimore, Md., and assume command of the service, relieving Passed Assistant Surgeon C. W. Wile.

YOUNG, G. B., Passed Assistant Surgeon. Upon being relieved by Passed Assistant Surgeon B. W. Brown, to proceed to Chicago, Ill., and assume command of the service.

Board Convened.

Board convened to meet at Chelsea, Mass., April 3, 1905, for the physical examination of Pharmacist Malcolm McKay to determine his fitness for promotion to the grade of pharmacist of the first class. Detail for the board—Surgeon R. M. Woodward, chairman. Acting Assistant Surgeon F. H. Cleaves, recorder.

Army Intelligence:

Official List of Changes in the Stations and Duties of Officers serving in the Medical Department of the United States Army for the week ending April 1, 1905:

BARTLETT, COSAM J., First Lieutenant and Assistant Surgeon. Relieved from duty at the Army and Navy General Hospital, Hot Springs, Ark., and assigned to duty at Fort Miley, Cal.

MUNSON, E. L., Captain and Assistant Surgeon. Granted ten days' leave of absence, with permission to apply for thirty days' extension.

SHORTLIDGE, E. D., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Miley, Cal., and ordered to the Army and Navy General Hospital, Hot Springs, Ark.

THOMASON, H. D., Captain and Assistant Surgeon. Advanced to the rank of captain.

WELLS, GEORGE M., Major and Surgeon. Ordered to proceed from San Francisco, Cal., to Hot Springs, Ark., and report to commanding officer, Army and Navy General Hospital, for treatment therein.

Births, Marriages, and Deaths.

Married.

FOARD—HACK.—In Baltimore, Maryland, on Wednesday, March 22nd, Dr. William R. Foard and Miss Flora Norris Hack.

O'BRIEN—McWILLIAMS.—In Baltimore, Maryland, on Thursday, March 23rd, Dr. Jerome O'Brien and Miss Kate McWilliams.

SAPPINGTON—PORTER.—In Baltimore, Maryland, on Thursday, March 23rd, Dr. Earl N. Sappington and Miss Hattie C. Porter.

TADDIKEN—TATE.—In Mount Upton, N. Y., on Tuesday, March 21st, Dr. Paul Gerald Taddiken and Miss Lena Millsbaugh Tate.

TANEYHILL—CRANSTON.—In Washington, D. C., on Saturday, March 25th, Dr. G. Lane Taneyhill, Jr., and Miss Ethel Cranston.

Died.

ARMSTRONG.—In St. Louis, Missouri, on Wednesday, March 22nd, Dr. George M. Armstrong.

BODENHAMER.—In New Rochelle, N. Y., on Friday, March 31st, Dr. William Bodenhamer, in the ninety-seventh year of his age.

BONESTEEL.—In Troy, N. Y., on Monday, March 20th, Dr. William M. Bonesteel.

CHAFFERS.—In Detroit, Michigan, on Sunday, March 26th, Dr. E. A. Chaffers, in the forty-third year of his age.

COOK.—In San Francisco, California, on Monday, March 20th, Dr. Fernando C. Cook, in the seventy-ninth year of his age.

CORSE.—In Gardenville, Maryland, on Thursday, March 23rd, Dr. George F. Corse, in the sixty-sixth year of his age.

CRANE.—In Kosciusko, Mississippi, on Friday, March 24th, Dr. C. A. Crane.

DANNE.—In New York, on Monday, March 27th, Dr. Frederick Danne, in the sixty-ninth year of his age.

DOLAN.—In Detroit, Michigan, on Tuesday, March 21st, Dr. Theodore C. Dolan, in the twenty-sixth year of his age.

DOREN.—In Columbus, Ohio, on Thursday, March 23rd, Dr. Gustavus A. Doren, in the sixty-eighth year of his age.

FILLER.—In Washington, D. C., on Wednesday, March 22nd, Dr. Charles W. Filler, in the forty-fifth year of his age.

FWOWLE.—In Milwaukee, Wisconsin, on Wednesday, March 22nd, Dr. Henry Fowle, in the seventy-sixth year of his age.

FOX.—In Baltimore, Maryland, on Wednesday, March 29th, Dr. Fabius Fox, in the forty-first year of his age.

GARLAND.—In Syracuse, N. Y., on Monday, March 20th, Dr. John J. Garland, in the thirty-second year of his age.

KLIPEL.—In St. Louis, Missouri, on Friday, March 17th, Dr. H. A. B. Klippel, in the thirtieth year of his age.

LEICK.—In Cleveland, Ohio, on Friday, March 31st, Dr. George F. Leick, in the fiftieth year of his age.

OLCOTT.—In Brooklyn, N. Y., on Thursday, March 30th, Dr. Charles A. Olcott, in the fiftieth year of his age.

PORTER.—In Paris, Tennessee, on Monday, March 20th, Dr. Joseph H. Porter, in the eighty-first year of his age.

REYNOLDS.—In Colorado Springs, Colorado, on Thursday, March 23rd, Dr. C. J. Reynolds.

RICE.—In Passaic, New Jersey, on Monday, March 27th, Dr. Frank H. Rice, in the seventy-sixth year of his age.

ROGERS.—In Elmer, New Jersey, on Monday, March 27th, Dr. Harry C. Rogers.

SITTEL.—In Cincinnati, Ohio, on Saturday, March 25th, Dr. Theodore Sittel, in the seventy-seventh year of his age.

SULLIVAN.—In Brooklyn, N. Y., on Monday, March 27th, Dr. Richard H. Sullivan, in the fifty-first year of his age.

TANSLEY.—In New York, N. Y., on Saturday, March 25th, Dr. John Oseroff Tansley, in the sixty-first year of his age.

THOMPSON.—In Washington, D. C., on Tuesday, March 21st, Dr. Richard Hamilton Thompson, in the eighty-seventh year of his age.

WARDER.—In Philadelphia, on Saturday, March 25th, Dr. William H. Warder, in the seventy-second year of his age.

WARDNER.—In La Porte, Indiana, on Friday, March 17th, Dr. Horace Wardner, in the seventy-sixth year of his age.

WHITEHEAD.—In Greenwood, Mississippi, on Saturday, March 25th, Dr. N. E. Whitehead.

WHITING.—In Janesville, Wisconsin, on Monday, March 27th, Dr. J. B. Whiting, in the eighty-third year of his age.

CASES OF ENTEROPTOSIS AND CARDIOPTOSIS WITH RETURN TO THE NORMAL.

By MAX EINHORN, M. D.

NEW YORK.

PROFESSOR OF MEDICINE AT THE NEW YORK POSTGRADUATE
MEDICAL SCHOOL.

In regard to the ætiology of enteroptosis and cardioposis, the last word has not yet been spoken. Some authors assume the existence of a congenital defect. Even if this be true in some cases, it certainly plays no part in the majority. Visceral ptosis is most frequently caused by states of inanition, no matter of what origin. Predisposing factors are the corset, constriction of the abdomen, getting up too soon after confinements, etc., although these are not really absolutely essential in bringing about this condition. A high degree of long continued subnutrition alone is sufficient to cause marked enteroptosis and cardioposis. This at once indicates the line of treatment to be pursued in order to cure visceral ptosis, viz., the rebuilding of the organism.

That a movable kidney may be entirely cured by medical means was first proved by Henderson.¹ I have since observed such cases.² Notwithstanding the importance of this subject, not much is to be found about it in literature, and the fact that the prolapsed kidney may be restored to a normal position has certainly not yet become generally known to physicians. For this reason I have deemed it proper to discuss the subject, and shall first describe some cases of visceral ptoses in which the displaced organs have returned to their normal places.

CASE I.—January, 1900, Miss H. M., 33 years old, seamstress, complains of lack of appetite, poor sleep, constipation, and occasionally palpitation of the heart. The patient is rather thin. Examination of the chest organs shows a normal condition. The stomach extends about a hand's

width below the navel. The liver dulness begins at the lower margin of the seventh rib and projects two fingers beyond the right costal margin. About two thirds of the right kidney can be palpated on deep inspiration. Diagnosis: Enteroptosis, gastroposis, hepatoposis, right nephroposis, neurasthenia.

January 14, 1905, patient presents herself again, having gained 30 pounds in weight. Examination now reveals normal conditions as regards the position of the stomach, liver, and kidney.

CASE II.—February, 1901, Miss A. R., a teacher, about 38 years old, complains of violent diarrhoea and some cough. Examination of the lungs shows slight dulness at the apex anteriorly on the right side and fine râles. Heart normal. On deep inspiration the right kidney can be entirely palpated, being, therefore, movable in the third degree. The stomach extends about a hand's width below the navel. Weight of patient, about 100 pounds. Diagnosis: Catarrh of the right apex of the lung, enteroptosis, right movable kidney, gastroposis, chronic enteritis. She was treated for some time, according to the usual methods and improved.

January 20, 1905, she again came to the office after a long absence. She now weighed 130 pounds, having gained 30 pounds in the last few years. Her stools were normal. She had complained occasionally of a slight cough and recently of pain in the epigastrium. She is now again examined. In the right lung we find anteriorly a few râles at the apex. Stomach extends to one finger's width above the navel. The right kidney cannot be palpated on deep inspiration. The marked enteroptosis has, therefore, disappeared completely.

CASE III.—C. D. H., 40 years old, merchant, has suffered from his stomach for the last twenty years. He feels bloated two hours after meals and has some nausea. He frequently brings up a little watery fluid, belches a few times, and then feels better. During the last years he has lost from 12 to 15 pounds. He has always been a very rapid eater all his life. He is troubled with palpitation of the heart, but does not get short of breath. He is very much depressed and melancholy. The relative dulness of the heart begins at the lower margin of the fourth rib; the apex beat is not plainly discernible. The heart sounds are loudest in the seventh intercostal space, but murmurs are absent. The stomach extends two fingers' widths below the navel. The upper boundary of the liver dulness begins in

¹F. Henderson: A Case of Movable Kidney Permanently Cured. *Glasgow Medical Journal*, Vol. XX, 1883, p. 329.

²Max Einhorn: Remarks on Enteroposis. *Medical Record*, April 13, 1901.

the right mamillary line in the seventh intercostal space and extends about four fingers' widths below the margin of the ribs. The right kidney is movable in the fourth degree, the left in the first. Examination of the stomach contents one hour after Ewald's test breakfast shows normal conditions. The diagnosis of enteroptosis, cardioposis, and neurasthenia was made. The patient was given *magnesia usta* with *feratin*, advised to wear an abdominal supporter, and told to eat frequently (five times daily).

March 30, 1904, patient says that he has gained 25 pounds. He feels perfectly well. Examination reveals that the heart dulness begins at the upper margin of the third rib. The stomach extends to one finger's width above the navel, the liver does not project beyond the lower margin of the ribs. Neither the left nor the right kidney can be palpated. Therefore the heart, stomach, liver, and kidneys are in their normal places.

CASE IV.—J. C. R., 31 years old, engineer, has never been sick, with the exception of scarlet fever. Until six years ago he always had a good stomach; at that time he noticed that he was losing in weight. Appetite was moderate, bowels constipated. He complains of an uncomfortable feeling in the abdomen about two to three hours after meals, as well as of belching. Present condition: The heart dulness begins at the lower margin of the fourth rib; heart sounds are normal; liver dulness begins two to three fingers' widths above the lower margin of the ribs in the right mamillary line and extends three fingers' widths below the navel. The stomach extends about one hand's width below the navel. The right kidney is movable in the third degree. Examination of the stomach about one hour after Ewald's test breakfast shows a high degree of acidity. The patient was told to eat amply, to wear an abdominal supporter and was given *alkalies* internally.

January 5, 1905, patient says that he has gained 10 pounds in weight. He feels much better. Examination of the chest organs shows that the heart dulness begins at the normal place (third rib); the condition of the kidney and stomach, however, has remained the same (kidney movable in the third degree, stomach two to three fingers' widths below navel). The liver, however, occupies a more normal position, the dulness beginning at the upper margin of the seventh rib and extending to about one finger's width below the margin of the ribs.

CASE V.—November 23, 1903, J. A., 44 years old, *méchant*, complains of frequent attacks of headache, rapid fatigue, frequent belching, and constipation. Examination shows that the heart dulness begins at the lower margin of the fourth rib. Heart sounds are normal. The liver dulness begins at the lower margin of the seventh rib, and extends in the right mamillary line two to three fingers below the margin of the ribs. The stomach extends a hand's width below the navel. Treatment consists in frequent feedings and the wearing of an abdominal supporter.

January 20, 1905, patient reports again, saying that he had gained 15 pounds and that he is feel-

ing perfectly well; he left off his abdominal supporter lately. Examination reveals that the heart dulness begins at the third rib, liver dulness in the right mamillary line at the lower margin of the sixth rib, and does not project beyond the costal margin. The stomach extends to a finger's width above the navel.

CASE VI.—March 21, 1904, Reverend Dr. R. G., 40 years old, complains of pains in his stomach about four to five hours after meals or shortly before meals, and of rapid fatigue when at work. When he partakes of food the pain is better. He sleeps poorly and suffers from constipation. Examination reveals: heart dulness begins at the lower margin of the fourth rib. Heart sounds are normal. Nothing abnormal can be discovered in the lungs. Liver dulness begins in the right mamillary line at the lower margin of the eighth rib and projects three fingers' widths beyond the costal margin. The stomach extends a hand's width below the navel. The diagnosis is: *Cardioposis*, *hepatoposis*, *gastroposis*, *gastral-gokenosis*. The patient is told to eat well, to wear an abdominal supporter, and is given one decigramme of *zinc valerianate* with three decigrammes of *ferratin* twice daily.

December 21, 1904, patient reports that he has gained 6 pounds, that he is feeling much better and sleeping well. He is again examined and the following is found: Heart dulness begins at the upper margin of the third rib. Liver dulness begins at the lower margin of the seventh rib and reaches two fingers' width below the right costal margin. Stomach reaches two fingers below navel.

Cases of this kind are not by any means so very rare, and I have simply selected the above from a large number of similar observations. I am convinced that nearly every clinician has seen cases resembling these. They illustrate two points: first, that a complete return to the normal of the prolapsed organs is possible; and, secondly, the importance played by an increase of the bodily weight. In all these cases after the patient had gained in weight, a better position of the organs resulted. The explanation for this process of restitution is not so easy. It seems, however, that an increase of fat around certain organs (kidneys, heart) as well as an improved general condition is an important factor.

According to some observations it seems to me, that the heart is the first organ to return to its normal location, even before a change in position can be discerned in the other organs. A return to the normal seems also to be more frequent in *cardioposis* than in *ptosis* of other viscera. As will be gathered from the above histories, the treatment consisted mainly in the wearing of a properly fitted abdominal supporter and ample feeding. That the last factor is the more important of the two may be inferred from the fact that the prolapsed heart returned to the normal after

an increase in bodily weight. The supporter under these circumstances can hardly have exerted an influence, and we must therefore attribute the favorable result to the improvement in nutrition.

In my article on enteroptosis I have already pointed out the importance of ample feeding in the treatment of this affection. Here I should like to emphasize this point once more and to add that in almost every case when desirable an increase of bodily weight can be established by a systematic augmentation of the quantity of food ingested. Practically this may be done according to the principles laid down by me in a recent paper.³

Even if the organs do not return to the normal in every instance, yet the prognosis is nearly always good. In almost all cases it is possible to relieve all the subjective symptoms by a rational treatment. But even to that end ample and proper feeding is the point of paramount importance.

20 EAST SIXTY-THIRD STREET.

DIETL'S CRISIS AND SOME CASES OF MOVABLE KIDNEY.

By L. W. ATLEE, M. D.,

PHILADELPHIA.

In making the selection of the following cases for publication there have purposely been omitted any representatives of that large class, the nervous female, presenting hysterical or neurasthenic symptoms, which, like the poor, is always with us. They present the usual motley array of symptoms so well known to every busy practitioner, and so difficult or impossible to deal with as to relief. It is not so long since that the ovaries bore the brunt of the blame for these manifestations; the sufferers were assured their ovaries were cystic, atrophic, or what not. They were advised to have the supposedly offending organs removed. Unfortunately the results were most disappointing, and, if one may judge by what is seen of the mutilated ones, not only do the original symptoms continue, but other and more serious symptoms are added. Hardly had the thinking men of our profession relegated spaying for the relief of this condition among the measures found wanting, when behold! the movable kidney comes to the relief of those of weak diagnostic and logical power of deduction. Now the discovery of a kidney that moves, in these cases, is fixed upon as the *fons et origo mali*. The offending kidney must be stitched fast, and all will be well. But is it? From our observation of the curative effects of this operation for the relief of the nervous symp-

toms in these cases the results have been absolutely nil.

"Far too much stress has been laid upon the condition of late years; if detected accidentally it is well not to let the patient know of its presence. The symptoms often date from the knowledge." Osler, *Practice of Medicine*, p. 847, 1903.

It is a very different matter when the movable kidney is producing symptoms due to the physical effects of its malposition. "Scarcely any mention is made of such symptoms, which were first described by Dietl in 1864, and a more widespread knowledge of their occurrence in connection with this condition is desirable." *Op. cit.*, p. 848.

These attacks come on suddenly and are characterized by severe abdominal pain, nausea, vomiting, and collapse, there are chills and sometimes high fever, I have seen the thermometer in an exceptional case show as high as 105° in a very hysterical subject. A practitioner who had seen this case just previous to my visit had made a diagnosis of typhoid fever with peritonitis; all the serious symptoms had subsided in twenty-four hours.

Among the more serious effects produced by a floating kidney is interference with the continuity of the intestinal tube, or stoppage of the bile duct. The circulation in the renal vessels, and the patency of the ureter may also be impaired, causing a temporary, or in time a permanent hydronephrosis. The kidney has also been looked upon as the cause of various grades of downward displacement of the viscera, but this requires confirmation. We see it cause a moderate grade of dilatation of the stomach due to pyloric and duodenal obstruction. Edebohls considers the kidney responsible for certain cases of appendicitis, but the explanation is not very satisfactory.

Before attributing effects to a kidney we have found to be floating, it is well to bear in mind that it is quite common to encounter considerable degrees of downward displacement of the viscera without any subjective symptoms at all. Subjective and nervous symptoms date usually from some cause injuring the general health, as severe nervous strain or shock. In the case of Mrs. McG., though no change could be made out as to the position of the abdominal viscera, all the subjective symptoms disappeared with the great improvement in the general health.

A reference to the literature on the subject will confirm the belief that a great variety of anatomical conditions are met with in the extreme grades of floating kidney—many different arrangements of bands, both cellular and peritoneal, passing from the kidney to various organs, thus in a way accounting for the many and varying effects on their functions.

³Max Einhorn: The Art of Increasing and Decreasing the Bodily Weight at Will. *Medical Record*, July 18, 1903.

Mrs. R. N., aged 42 years, laboring class, mother of five children. When seen first she was in bed, and had been under treatment by another practitioner during past five days for what he called appendicitis. She had been unable to retain anything in her stomach; the bowels were obstinately constipated. The woman had the appearance of being very ill, in a condition we call collapse, the pulse rapid, weak, and small, in the mouth the thermometer marked 102.5°, but the hands and feet were cold, and the finger nails cyanotic. The abdomen was tympanitic and distended by what seemed the cæcum and ascending colon. There was bitter complaint of pain extending from the right hypochondrium to the right groin. Rigidity of the right rectus muscle was not marked. The extreme tenderness prevented any thorough palpation, but a freely movable tumor was immediately recognized on palpating the right lumbar region. The thoracic organs were normal. The urine contained bile, but no other pathological ingredients. The treatment was merely symptomatic, opium, belladonna, and extract of colocynth being given internally (they did not cause vomiting), and turpentine stupes applied, as well as enemata containing turpentine administered. In the following twenty-four hours the bowels had freely moved and much flatus had been passed, the colonic distention having largely disappeared. The pain and nausea had ceased, the urine contained more bile pigments, and the conjunctiva and skin were decidedly bile tinged. At this time the movable lump was easily recognizable as a floating kidney, and could be pushed into its bed, and into the iliac region and almost across the middle line. A cough, or in fact any straining movement on the patient's part, made it quickly pop out again from its normal position. Pressure in the gall bladder region caused no pain. The further history of the case contains nothing of interest beyond the fact of her progressing uninterruptedly to the enjoyment of fair health. Some fourteen months after this she was seen again in a much milder attack which lasted only one day, and was not accompanied by symptoms indicating interference with the patency of the bile ducts. In this woman the abdominal walls were very lax, and there undoubtedly existed some downward displacement of the intestines and stomach. We may add that the usual means at our command were made use of to convince ourselves the lump was not an enlarged gall bladder. The existence of gallstones is only for conjecture, for it is conceded a floating kidney can and does at times produce such biliary interference as to cause jaundice. (Henry Morris, *Surg. Dis. of Kid. and Ureter*, Vol. 1, p. 128. London, 1901.)

However, Osler says "some writers have described pressure upon the gall ducts and bladder, with jaundice, but it is not very likely to occur." *Pract. Medicine*, p. 848, 1903.

"Transient attacks of jaundice are said not to be unfrequent, but I have never personally witnessed them." "Autopsy supports Landau's theory: A right floating kidney if carefully drawn forward or downward, causes traction in the duodenum at a point

2 to 3 cm. below the junction of the biliary ducts, and though it does not occlude the lumen it interferes with the contents of the bowel sufficiently to impair digestion and cause biliary obstruction." *Surgical Dis. of Kid. and Ureter*, Morris, Vol. 1, 113-114.

"In other instances intestinal obstruction has been attributed to renal pressure." Allbutt's *Syst. of Med.*, Vol. V, p. 344. "In Frank's case a peritoneal band from the upper portion of the kidney was attached to the duodenum in such a manner that, when the kidney was drawn down, the band dragged upon the duodenum and kinked it, thus practically occluding its lumen. Similar bands have been seen by Lenharz and Weisker, and I have been able to demonstrate the existence of folds of peritonæum of this nature in our dissecting room." "The drag of the peritonæum on the duodenum is probably the commonest cause of the temporary jaundice which often accompanies the gastric crisis." *Op. cit.*, p. 346.

In this case we have symptoms suggestive of gallstones, intestinal obstruction, and appendicitis, and on first approaching such a combination one may easily be led by a habit of "cocksureness," or snapshot diagnosis, to settle on any one of the three possibilities and proceed accordingly. "The Dietl's crises have been mistaken for appendicitis." Osler, *Op. cit.*, p. 526. It is necessary to have an accurate knowledge of the symptomatology of the diseases simulated, as well as of the disease presented for our diagnosis in this case, as in any other. For in these days of active surgical interference in all of these morbid conditions a laparotomy would be considered imperatively demanded.

Mrs. McG., widow, aged 41 years, cook. When first consulted by this woman my first thought was what a typical picture she presented of a case of cancer of the stomach, and the train of symptoms enumerated seemed to bear out strongly this first impression. She was very tall, emaciated, and of a ghastly complexion. No matter what she ate she vomited, in the course of one to three hours. After eating severe pain came on in the epigastrium, and was relieved only by vomiting. The vomitus was very sour and put her teeth on edge. The condition had been getting worse for the past eight months, though she stated she had been troubled with dyspeptic symptoms for years. She had left a hospital a few days ago; while there her stomach had been better on the diet she received, but all the symptoms immediately reappeared on her return to her home. She had been told she had gastroptosis, and advised to have an operation. The general condition was one of extreme inanition, the thoracic organs were normal, and the urine showed no morbid characteristics; it was scant and contained

lithates. In passing the hand over the abdomen in the recumbent position a tumor was felt in the right lumbar and iliac regions; it was very movable, pressure producing a sickening sensation of pain. It could be reduced into the kidney position in the right flank, where it remained until displaced by a deep inspiration or cough, or the assuming of the erect posture. The abdominal walls were relaxed, but there was no intestinal distention. It could not be made out that the body of the stomach was decidedly depressed, or that the organ was dilated. The symptoms suggested pyloric obstruction. There were no nervous symptoms of a neurasthenic or hysterical character. There had never been any severe crises of pain, vomiting, and prostration, nor were there complaints of pain in the back or lower thorax. Digestive disturbances, constipation, and the resulting weakness were the subjective conditions. This woman was given a simple abdominal supporter with a pad in the hypogastrium. This is especially mentioned, as she was much more comfortable with than without it; many of these patients cannot tolerate a supporter of any kind. The diet at first consisted principally of freshly expressed beef juice, relieved by occasional feedings of clam juice, or equal parts of milk and lime water. As her condition improved she gradually took up beefsteak, mutton chops, stale bread, eggs, and, lastly, vegetables of the starchy group. In three months she put on thirty pounds of flesh, felt strong and well, and returned to her work. She had to be very careful about certain articles of food, and needed always to take laxatives. Medication consisted of bismuth subnitrate with the digestive ferments, principally ingluvin, which acted like a specific in her case; to these strychnine in small doses was added. The improvement in this case was as unexpected as it was gratifying. She still continues in very good health for over a year now, working steadily. The only complaint she has had was a mild attack of sciatica in the right leg and hip, which was of long duration and yielded to antilithemics and counterirritation.

"The disturbances affecting the different parts of the digestive canal are sometimes very severe. Mathieu states that the percentage of cases of movable kidney in dyspeptics is very large; and it is well in cases of unaccountable disorders of digestion to search for the existence of nephroptosis. The symptoms are gastric pain, loss of appetite, frequent vomiting, and the other signs of gastric catarrh; the bowels are often obstinately constipated, the body becomes emaciated. The appearance in several cases has been suggestive of malignant disease of the stomach, as described by Lochhead." Allbutt, *Syst. of Med.*, Vol. V, p. 344.

CASE NO. 3.—Mrs. G., aged 28 years, mother of two healthy children, is rather short and thick set, well nourished. For the past year has at times been troubled with dyspeptic symptoms, eructations, and discomfort after meals, bowels

occasionally costive. Frequently has pain in lumbar region, right hypochondrium, and inguinal region. Pain in back sometimes very severe at night. Has had some half dozen attacks of most excruciating pain in regions described, accompanied by nausea and vomiting with straining. She had been told by an eminent practitioner the attacks were due to gallstones. There had never been any jaundice after these attacks. Examination of the abdomen showed the walls to be more relaxed than normal, but not greatly so. The right kidney was movable in a vertical line some four inches, but did not float. The lower pole of the left kidney was palpable and had the fancifully called "cinder-sifting" movement. No other organic lesion was found. The urine contained many oxalate of lime crystals and much epithelium showing irritation of the urinary tract. This woman was neither hysterical nor neurasthenic, and did not find the occasional pains and soreness of much moment, but she dreaded the attacks of pain, nausea, and vomiting, and felt at these times as if she were going to die. She was advised to get a supporter for the abdomen, and given directions as to diet and medication directed to aiding the digestion. During the following ten months she reported several times at the office and by letter that she was keeping comfortable. One evening at this time her husband called by telephone from their residence in the suburbs of Philadelphia for me to come as his wife had one of the terrible attacks. When seen her condition was such it was easy to understand her dread of these crises; the pain, nausea, and vomiting were accompanied with a condition bordering on collapse, great cardiac weakness, and cold extremities. Such examination as was possible showed great superficial sensitiveness all over the right side of the abdomen; it was not painful on deep pressure excepting the kidney. If the attention was withdrawn, deep pressure in the gall bladder region was not painful. A hypodermic of morphine, and a mustard plaster afforded relief, so that she slept most of the night and was able to resume her usual occupations on the following day.

Mrs. B. I., aged 27 years, Italian, mother of ten children, the youngest one year old. Has no distinct recollection when she first began to experience discomfort, but has always been nervous. She had occasionally, perhaps once in three or four months, severe attacks of pain in the right side of the thorax; these pains shot into the right iliac region also. When four months' pregnant with her last child she had walked to a nearby clinic of a large hospital. At this time she had some pain in the aforementioned region. She was advised to have her appendix removed. This was done, and she recovered quickly and returned home in a few weeks. While carrying her child she had no more attacks of pain, but a few months after its birth she had a return of the same pains. A second visit to the hospital brought forth the diagnosis of "inflammation of the ovary." She was urgently advised to have the ovary removed. About this time she was first seen by me. She is a well developed and nourished, rosy cheeked woman. A careful examination of the pelvic or-

gans revealed nothing out of the normal. She had a fairly good digestion, but was costive. She complained of an intercostal neuralgia, and there were the usual spots painful on pressure in this neuralgia. There was pain in the right loin at times, sometimes extending into the right groin. She had plenty of nourishment for her baby, which was big and fat. The right kidney was freely movable in a vertical direction and the fingers could be placed over the upper pole of the organ. She was mildly hysterical and very anxious about herself. The treatment was entirely symptomatic, and gave great relief. She was seen in a severe attack, later, of the intercostal neuralgia, with subjective symptoms of a hysterical character. There was no vomiting, fever, or urinary symptoms during the attack. Mild counter irritation and some potassium bromide and ammonium valerianate gave relief. During the past year she has been in my office frequently with relatives or friends to be treated, but makes no serious complaint about herself, and says she does not mind some occasional discomfort, so long as she knows there is nothing serious the matter.

"Symptoms of chronic appendicitis are considered by Edebohls to be a very frequent complication of movable kidney on the right side." Morris, *Op. cit.*, p. 114. In this regard Osler, who rarely misses a point, says: "In other instances the attacks of pain may be thought to be due to intestinal disease are due to recurring appendicitis." *Op. cit.*, p. 848.

George B., aged 28 years, at one time professional baseball player, now a moulder in plaster of paris, is well nourished, but sallow. He comes of a very neurotic family; his mother has spasmodic asthma, and two sisters suffer from severe neuralgias at times. He was at one time an enthusiastic baseball player, but has not played for the past three years. For some time he has complained of troublesome digestion, constipation, and palpitation of the heart. His relatives have noticed that he has become moody, talks but little, except of his health, and he has lost all interest in his family and work. He will sit about the house for days at a time brooding. He smokes a pipe a good deal, and drinks freely of tea and coffee, but not more than was usual heretofore. When first seen he was in bed and complained of feeling dizzy, of palpitation of the heart, and had some pain in the right lower thorax, right lumbar, and right umbilical regions. There was no tenderness or rigidity of the abdomen. His pulse was small, regular, and 140 per minute; temperature normal. Tongue coated, breath heavy. Examination failed to reveal any diseased organs. The lower two thirds of the right kidney was palpable, and could be pushed into its bed, but would descend again on forced inspiration or violent coughing. There was also a small reducible right inguinal hernia. The urine showed great quantities of oxalate of lime crystals, but there were no subjective symptoms of irritation of the urinary tract; there was no other abnormality about the urine. It is more than one year since this

man was first seen. Every effort has been made by treatment directed towards the correction of the stomach condition and the constipation, and general hygiene as to fresh air, bathing, and exercise to improve him, but beyond the fact of his being in apparently good general health, the condition of hypochondriasis is still the same. Many indefinite complaints have been made only to be changed for others at the next visit. However, this well known condition needs no further description, as it differs in no way in this case from the usual condition seen without movable kidney. (I have heard recently that this patient was much better and playing baseball as a professional.)

Of the nervous symptoms seen in nephroptosis, Osler says "in women the hysterical symptoms may be marked; and in men various grades of hypochondriasis." *Op. cit.*, pp. 847-848. No mention is made of this effect on the nervous system in the article on Nephroptosis in Allbutt's *System of Medicine*, but Morris says "during the course of the disease the general health of the patient is naturally much impaired; languor, debility, loss of flesh, hypochondriasis, great restlessness, great anxiety, hysteria, perversion of sensation, or of the special senses, and many other neurotic signs are some or other of them commonly present." Vol. I, p. 116. "So frequently are symptoms which are caused by the kidney referred to some other organ, so varied are the nervous and other disorders associated with the female genital organs, that it is often most difficult to say how much of the neurasthenic symptoms, how much of the abdominal pain and backache, how much of the gastroenteric disorder, or how much of the disturbed urinary functions is due to the movable kidney and how much to some other morbid condition, or indeed to a hysterical temperament." Morris, *Surgical Dis. of Kid. and Ureter*, Vol. I, p. 120.

2020 PINE STREET.

Testimonial to Dr. Lucy Bannister.—The resignation of Dr. Lucy A. Bannister as superintendent of the Mills Training School of Bellevue Hospital was distinguished by a gathering on April 7th, when a beautifully engrossed testimonial was presented by L. J. Rourke, on behalf of the students, while Walter M. Delevan, a recent graduate, made the speech which accompanied the presentation of a set of engraved resolutions from the graduating class. Dr. Nichols, of the medical division, also made a short address expressive of the general regret at Dr. Bannister's departure. Dr. Bannister is a graduate of the Pennsylvania Woman's College of Medicine. Before assuming the superintendency of the Mills Training School she held the position of superintendent in the Wisconsin General Hospital and Training School. She goes to Philadelphia to enter private practice.

INFLAMMATION OF THE GLANDS OF BARTHOLIN.

By CHARLES C. MILLER, M. D.,

CHICAGO.

A careful perusal of the literature upon acute inflammation of the gland of Bartholin will show that the condition described by the writers of to-day as an acute inflammation of the duct or gland is rather an inflammation subsequent to the occlusion of the duct of the gland, or one of its branches with the retention of secretions and discharges. Acute inflammation, without the retention of the secretions and pus formed, will differ widely from acute inflammation where secretions and inflammatory products are retained within duct and gland, both as to symptom complex and as to the subsequent outcome.

Where a woman develops an infection of the vulva, vagina, or urethra, accompanied by a profuse purulent discharge, the openings of the glands of Bartholin are constantly bathed in these discharges, which follow the line of least resistance. They are directed by the labia and by gravity toward the openings of the ducts of Bartholin's glands in the fossa navicularis. The imperfect, falciform, valvular fold, which can sometimes be demonstrated at the opening of Bartholin's duct cannot be expected to prevent an infection of the duct when the orifice of the duct is constantly bathed in a highly infectious discharge. All the tissues about the duct become inflamed and oedematous in many cases. This lessens the resistance to the invasion of the bacteria and the duct is lined with that variety of epithelial cells which are peculiarly favorable to the development of the gonococcus, the germ almost invariably responsible for the development of an acute vulvar, vaginal, or urethral inflammation.

When a woman is first infected with gonorrhœa she develops in not a few cases an acute vulvar inflammation, as well as a vaginitis and urethritis. In this case the entire genitalia become swollen, oedematous, and tender. A tingling, burning pain and more or less pruritus are noted. The mere gentle separation of the labia is painful. The gynecologist soon learns that these women have often but recently been violated. The introduction of the finger into the vagina causes severe pain, and but little information is elicited, so that the inspection of the parts and possibly the gentle separation of the labia is the extent of the examination made. Hidden among these acutely inflamed and exquisitely tender tissues are the infected, swollen glands, and ducts of Bartholin. There is no peculiar, striking, or distressing symptom to direct particular attention to them; they are inflamed, as are the tissues all about them, and inflammatory products, which

form in gland and duct, find free egress with the secretions of the gland into the fossa navicularis, where they mingle with the discharges from vulva, vagina, and urethra. It is thus not strange that an inflammation which has no symptoms to direct our attention to it should escape our notice.

I do not direct the attention of the profession to the frequent occurrence of acute inflammation of the duct and gland of Bartholin in order to propose some special treatment for this acute inflammation. The importance of recognizing acute inflammation lies in the fact that a very large number of such cases do not go on to complete resolution. The infection persisting in these structures contaminates the secretions of the gland and their discharge before and during intercourse exposes the partner to the dangers of infection. When the disease has quite disappeared from the remainder of the genital tract reinfection may occur from these discharges from the Bartholinian glands, and a pelvic inflammation ultimately developing may wreak irreparable damage in a patient who has previously escaped an ascension of the infection above the uterus.

Where there is a severe inflammation of the external genitals coupled with much swelling and tenderness, the palpation of the swollen gland of Bartholin is only possible with the patient under general anæsthesia. I have enjoyed the opportunity thus to examine several patients and have always found it possible to palpate the swollen gland. When the inflammation has somewhat subsided, it is also possible in quite a number of these cases to demonstrate the somewhat swollen and enlarged gland, if the patient is tolerant of pain. To palpate the gland the index finger should be introduced into the vaginal entrance and pressed somewhat backward; the thumb should then be pressed toward the vaginal finger, grasping the labium majus and intervening tissues. The tissues should then be allowed to slip through the fingers, and the gland will be felt, resembling very much a somewhat swollen lymphatic gland. If the gland is palpable, and an inflammation of the external genitals has but recently subsided, it is my opinion that the gland has been infected. Some anatomists have asserted that the gland when normal can be felt in the thin individual, but I do not believe this is correct if it has never been subjected to infection or trauma.

The inflammation sometimes subsides in the gland so rapidly that the gland cannot be felt when the acute inflammation has subsided, yet it remains infected. This is particularly likely to be the case in the woman who has more than the usual amount of subcutaneous fat. I have had one case of this kind where the woman had an acute inflammation

of the external genitals. The glands could not be felt during the acute inflammatory process owing to the swelling and tenderness interfering with a thorough examination. This patient was carefully treated, and after the inflammation of the parts subsided, efforts were made to palpate the glands without success. About a month after treatment had been discontinued, without any sign of a reinfection of the vulva, vagina, or urethra, an infection was demonstrated by the development of a purulent inflammation after retention of the secretions of the gland.

One would at first think that the presence of a purulent inflammation of the duct or gland might be demonstrated by expressing pus from the duct or gland by pressure, but this is not possible as a rule unless there is more or less obstruction to the duct allowing the retention of the pus in the dilated duct. Where it is possible to milk out a visible quantity of pus from the duct it is safe to infer that the duct is more or less strictured or that the secretions have become inspissated and have acted as a plug to the duct.

After an acute inflammation of the external genitals has subsided, we are able to palpate, in many of these cases, the gland in which complete resolution has not occurred. In others this will not be possible even though the gland is infected. If the patient is a woman fairly fleshy, the tissues will be well cushioned with fat, and if she has had no children, and the fascia and muscles are tense and resistant, palpation of the gland will be impossible unless it is very distinctly enlarged.

During an acute inflammation of the external genitals, the tissues all about the entrance of the duct of this gland are inflamed. When the inflammation of the vulva subsides and the tissues of the fossa navicularis gradually lose their congested appearance, if there has been an inflammation of the duct of the gland of Bartholin, we shall have the opening of the duct remain injected, if more or less inflammation persists in this duct. Pozzi has compared the opening of the duct with its purple red areolæ to a flea bite, and Sanger has called this the "gonorrhœal macule." This condition usually persists where the duct remains inflamed. In the absence of all other symptoms it is safe to infer that this woman has a condition which is a menace to herself and to any person who might have sexual relations with her.

The trauma incident to the birth of several children, and the trauma of frequent and violent intercourse or sexual abuse may result in the irritation and enlargement of the gland, where it is poorly protected by fat so that it becomes palpable, but I have never observed an acute inflammation

causing symptoms which could be attributed to trauma alone.

Mann, in his *System of Gynecology*, speaks of trauma as a factor in causing acute inflammation, but it is easy to see that the cases of which he is speaking are those in which a chronic infection of the duct and gland are complicated by stricture of the duct, the trauma merely favoring acute inflammation after cystic distention has developed.

CHRONIC INFLAMMATION OF THE DUCT AND GLAND WITHOUT OCCLUSION OF THE DUCT.

This is the condition which so often follows acute inflammation of the duct and gland. A few observers have recognized the frequency of this condition, but generally speaking gynecologists have overlooked it.

Reparative efforts are probably greater in the gland than in the duct, and in a percentage of cases, which it is hard to definitely estimate, the gland becomes entirely healthy, but the infection persists in the duct. It is sometimes easy to pronounce the gland infected, as one can easily palpate it as an enlarged, slightly tender mass. Where the woman is in good flesh, and the tissues are firm and resistant, even if it is enlarged and infected, it may not be palpable. In such a case, we are unable to say definitely as to the condition of the gland, even though we find conclusive evidence of the infection and disease of the duct. The opening of the duct will show as a purplish red injected point when the duct is diseased. In some cases the injection at the opening of the duct is very slight, in others it is easily apparent. A chronic inflammation of the duct will always be accompanied by more or less of a discharge. If there is no stricture of the duct, this will not accumulate in any considerable quantity in the lumen of the duct, and pressure along the course of the duct or over the gland may not serve to force out a drop at the opening of the duct, as a means of verification of the diagnosis. This is due to the fact that it is not easy to massage the duct and express a small accumulation from its lumen. Fascia, muscles, and fat protect it from the pressure.

For demonstrating the presence of pus in the duct, where pressure with the fingers fails to express a drop, a syringe of the type used in washing out the lacrymal passages in dacryocystitis is most useful. The fine point of this syringe can be introduced well into the duct, and a drachm or two of sterile water used to wash out the tract. The first portion of the fluid will contain more or less pus and shreds. This can sometimes be easily seen with the naked eye as the fluid escapes

from the duct, but in other cases it will be necessary to catch the fluid and hold it up to the light, as we do urine in examinations of the urine of patients with chronic gonorrhœa.

ANATOMY OF THE DUCT.

It will be necessary to consider the anatomy of the duct before a clear understanding of the treatment can be best acquired.

The orifice of the duct is found in the fossa navicularis, usually nearest the largest carunculæ myrtiformes, which represent the point of junction of the posterior and lateral vaginal walls above. The orifice is provided with an imperfect, falciform, valvular fold of mucous membrane on its outer aspect, which diminishes its size so that in some instances it is not more than one one hundredth of an inch in diameter, and when free from disease is not visible to the naked eye. It sometimes appears only as a minute opening; often, especially when diseased, it is surrounded by a lively red areola, and in many cases it may be noted as a small opening in the centre of a slight projection in the mucosa, due probably to a pouting of the mucosa of the duct.

The duct runs outward and upward toward the gland. Its course is easily estimated where the gland is palpable and the external orifice visible. It has been variously estimated as from one half to one inch in length and in the majority of instances it very closely approximates a length of three fourths of an inch. Its diameter probably varies from one sixteenth to one eighth of an inch. The duct is single until the gland is reached, when it usually divides into three branches. These branches continue to divide, the ultimate subdivisions becoming very minute. The duct is lined with cylindrical epithelium, and according to Kölliker its wall contains a delicate longitudinal layer of smooth, muscular fibres, and is two millimetres in thickness.

If the syringe used in the first examination passes readily into the duct, we can treat the case by daily irrigations with various antiseptic solutions. Of these the mildest is the saturated solution of boric acid. It will usually prove inefficient. Probably the best solution is the silver nitrate solution, beginning with a solution one fourth of one per cent. in strength. This is best used hot and from one to four drachms should be used for washing out the duct. The solution can be allowed to flow in rapidly, and will in this way be more likely to reach all portions of the duct. If the solution is used daily for two weeks in this way, we mechanically cleanse the duct a number of times and also bring in contact with its walls an active antiseptic. This solution is

irritating and we should soon substitute a milder solution, such as that of boric acid, and lengthen the interval between treatments to two days.

It is probably well in all cases to slit the opening of the duct before beginning treatment, and in a large percentage of cases this will be found necessary. This little procedure can be easily accomplished with a delicately pointed knife, such as is used in cataract operations. The cut should be made outward and backward, as it will then be more likely to divide the delicate fold of mucous membrane, which diminishes the calibre of the external opening of the duct. The cut should be free so as to insure that the external orifice will no longer be the smallest portion of the duct. The cut should be about an eighth of an inch in length. The calibre of the duct should then be tested with probes.

STRICTURE OF THE DUCT OF BARTHOLIN.
